    elseif method == 'shutdown' then
      callback(nil, nil)
    end
    request_id = request_id + 1
    return true, request_id
  end
  function srv.notify(method, params)
    if method == 'exit' then
      dispatchers.on_exit(0, 15)
    end
  end
  function srv.is_closing()
    return closing
  end
  function srv.terminate()
    closing = true
  end

  return srv
end

-- Define a config for the server, then enable it...
vim.lsp.config['my-server'] = {
  cmd = cmd_fn,
  filetypes = { 'lua' },
  root_markers = { '.git' },
}
vim.lsp.enable('my-server')

-- ...or call start() directly.
vim.lsp.start(
  { cmd = cmd_fn, name = 'my-server', root_dir = vim.uv.cwd() },
  { attach = true })
```

LSP HIGHLIGHT

lsp-highlight

Reference Highlights:

Highlight groups that are meant to be used by vim.lsp.buf.document_highlight().

You can see more about the differences in types here: https://microsoft.github.io/language-server-protocol/specification#textDocument_documentHighlight

hl-LspReferenceText
hl-LspReferenceRead
hl-LspReferenceWrite
hl-LspReferenceTarget
hl-LspInlayHint

LspReferenceText used for highlighting "text" references
LspReferenceRead used for highlighting "read" references
LspReferenceWrite used for highlighting "write" references
LspReferenceTarget used for highlighting reference targets (e.g. in a hover range)
LspInlayHint used for highlighting inlay hints

lsp-highlight-codelens

Highlight groups related to lsp-codelens functionality.

hl-LspCodeLens

LspCodeLens Used to color the virtual text of the codelens. See nvim_buf_set_extmark().

hl-LspCodeLensSeparator

LspCodeLensSeparator
Used to color the separator between two or more code lenses.

lsp-highlight-signature

Highlight groups related to vim.lsp.handlers.signature_help().

hl-LspSignatureActiveParameter

LspSignatureActiveParameter Used to highlight the active parameter in the signature help. See vim.lsp.handlers.signature_help().

LSP SEMANTIC HIGHLIGHTS

lsp-semantic-highlight

When available, the LSP client highlights code using lsp-semantic_tokens, which are another way that LSP servers can provide information about source code. Note that this is in addition to treesitter syntax highlighting; semantic highlighting does not replace syntax highlighting.

The server will typically provide one token per identifier in the source code. The token will have a `type` such as "function" or "variable", and 0 or more `modifiers` such as "readonly" or "deprecated." The standard types and modifiers are described here:

https://microsoft.github.io/language-server-protocol/specification/#textDocument_semanticTokens LSP servers may also use off-spec types and modifiers.

The LSP client adds one or more highlights for each token. The highlight groups are derived from the token's type and modifiers:

- `@lsp.type.<type>.<ft>` for the type
- `@lsp.mod.<mod>.<ft>` for each modifier
- `@lsp.typemod.<type>.<mod>.<ft>` for each modifier Use :Inspect to view the highlights for a specific token. Use :hi or nvim_set_hl() to change the appearance of semantic highlights:

```
hi @lsp.type.function guifg=Yellow        " function names are yellow
hi @lsp.type.variable.lua guifg=Green     " variables in lua are green
hi @lsp.mod.deprecated gui=strikethrough  " deprecated is crossed out
hi @lsp.typemod.function.async guifg=Blue " async functions are blue
```

The value vim.hl.priorities`.semantic_tokens` is the priority of the `@lsp.type.*` highlights. The `@lsp.mod.*` and `@lsp.typemod.*` highlights have priorities one and two higher, respectively.

You can disable semantic highlights by clearing the highlight groups:

```
-- Hide semantic highlights for functions
vim.api.nvim_set_hl(0, '@lsp.type.function', {})

-- Hide all semantic highlights
for _, group in ipairs(vim.fn.getcompletion("@lsp", "highlight")) do
  vim.api.nvim_set_hl(0, group, {})
end
```

You probably want these inside a ColorScheme autocommand.

Use LspTokenUpdate and vim.lsp.semantic_tokens.highlight_token() for more complex highlighting.

The following is a list of standard captures used in queries for Nvim, highlighted according to the current colorscheme (use :Inspect on one to see the exact definition):

@lsp.type.class Identifiers that declare or reference a class type @lsp.type.comment Tokens that represent a comment @lsp.type.decorator Identifiers that declare or reference decorators and annotations @lsp.type.enum Identifiers that declare or reference an enumeration type @lsp.type.enumMember Identifiers that declare or reference an enumeration property, constant, or member @lsp.type.event Identifiers that declare an event property @lsp.type.function Identifiers that declare a function @lsp.type.interface Identifiers that declare or reference an interface type @lsp.type.keyword Tokens that represent a language keyword @lsp.type.macro Identifiers that declare a macro @lsp.type.method Identifiers that declare a member function or method @lsp.type.modifier Tokens that represent a modifier @lsp.type.namespace Identifiers that declare or reference a namespace, module, or package @lsp.type.number Tokens that represent a number literal @lsp.type.operator Tokens that represent an operator @lsp.type.parameter Identifiers that declare or reference a function or method parameters @lsp.type.property Identifiers that declare or reference a member property, member field, or member variable @lsp.type.regexp Tokens that represent a regular expression literal @lsp.type.string Tokens that represent a string literal @lsp.type.struct Identifiers that declare or reference a struct type @lsp.type.type Identifiers that declare or reference a type that is not covered above @lsp.type.typeParameter Identifiers that declare or reference a type parameter @lsp.type.variable Identifiers that declare or reference a local or global variable

@lsp.mod.abstract Types and member functions that are abstract @lsp.mod.async Functions that are marked async @lsp.mod.declaration Declarations of symbols @lsp.mod.defaultLibrary Symbols that are part of the standard library @lsp.mod.definition Definitions of symbols, for example, in header files @lsp.mod.deprecated Symbols that should no longer be used @lsp.mod.documentation Occurrences of symbols in documentation @lsp.mod.modification Variable references where the variable is assigned to @lsp.mod.readonly Readonly variables and member fields (constants) @lsp.mod.static Class members (static members)

EVENTS

lsp-events

LspAttach LspAttach

After an LSP client performs "initialize" and attaches to a buffer. The autocmd-pattern is the buffer name. The event-data (type: `vim.event.lspattach.data`) has the client ID.

Example:

```
vim.api.nvim_create_autocmd('LspAttach', {
  callback = function(ev)
    local client = vim.lsp.get_client_by_id(ev.data.client_id)
    -- ...
  end
})
```

Note: If the LSP server performs dynamic registration, capabilities may be registered any time _after_ LspAttach. In that case you may want to handle the "registerCapability" event.

Example:

```
vim.lsp.handlers['client/registerCapability'] = (function(overridden)
  return function(err, res, ctx)
    local result = overridden(err, res, ctx)
    local client = vim.lsp.get_client_by_id(ctx.client_id)
    if not client then
      return
    end
    for bufnr, _ in pairs(client.attached_buffers) do
      -- Call your custom on_attach logic...
      -- my_on_attach(client, bufnr)
    end
    return result
  end
end)(vim.lsp.handlers['client/registerCapability'])
```

LspDetach LspDetach

Just before an LSP client detaches from a buffer. The autocmd-pattern is the buffer name. The event-data (type: `vim.event.lspdetach.data`) has the client ID.

Example:

```
vim.api.nvim_create_autocmd('LspDetach', {
  callback = function(ev)
    -- Get the detaching client
    local client = vim.lsp.get_client_by_id(ev.data.client_id)

    -- Remove the autocommand to format the buffer on save, if it exists
    if client:supports_method('textDocument/formatting') then
      vim.api.nvim_clear_autocmds({
        event = 'BufWritePre',
        buffer = ev.buf,
      })
    end
  end,
})
```

LspNotify LspNotify

This event is triggered after each successful notification sent to an LSP server.

The event-data (type: `vim.event.lspnotify.data`) has the client_id, LSP method, and parameters.

Example:

```
vim.api.nvim_create_autocmd('LspNotify', {
  callback = function(ev)
    local bufnr = ev.buf
    local client_id = ev.data.client_id
    local method = ev.data.method
    local params = ev.data.params

    -- do something with the notification
    if method == 'textDocument/...' then
      update_buffer(bufnr)
    end
  end,
})
```

LspProgress LspProgress

Upon receipt of a progress notification from the server. Notifications can be polled from a `progress` ring buffer of a vim.lsp.Client or use vim.lsp.status() to get an aggregate message.

If the server sends a "work done progress", the `pattern` is set to `kind` (one of `begin`, `report` or `end`).

The event-data (type: `vim.event.lspprogress.data`) has `client_id` and `params` properties, where `params` is the request params sent by the server (see `lsp.ProgressParams`).

Examples:

Redraw the statusline whenever an LSP progress message arrives:

```
autocmd LspProgress * redrawstatus
```

Emit a progress-message on LSP progress events:

```
vim.api.nvim_create_autocmd('LspProgress', { buffer = buf, callback = function(ev)
    local value = ev.data.params.value
    vim.api.nvim_echo({ { value.message or 'done' } }, false, {
      id = 'lsp.' .. ev.data.params.token,
      kind = 'progress',
      source = 'vim.lsp',
      title = value.title,
      status = value.kind ~= 'end' and 'running' or 'success',
      percent = value.percentage,
    })
  end,
})
```

See also:

- https://github.com/MicrosoftDocs/terminal/blob/main/TerminalDocs/tutorials/progress-bar-sequences.md

LspRequest LspRequest

For each request sent to an LSP server, this event is triggered for every change to the request's status. The status can be one of `pending`, `complete`, or `cancel` and is sent as the `{type}` on the "data" table passed to the callback function.

It triggers when the initial request is sent (`{type} == pending`) and when the LSP server responds (`{type} == complete`). If a cancellation is requested using `client.cancel_request(request_id)`, then this event will trigger with `{type} == cancel`.

The event-data (type: `vim.event.lsprequest.data`) has the client ID, request ID, and request (described at vim.lsp.Client, `{requests}` field). If the request type is `complete`, the request will be deleted from the client's pending requests table after processing the event handlers.

Example:

```
vim.api.nvim_create_autocmd('LspRequest', {
  callback = function(ev)
    local bufnr = ev.buf
    local client_id = ev.data.client_id
    local request_id = ev.data.request_id
    local request = ev.data.request
    if request.type == 'pending' then
      -- do something with pending requests
      track_pending(client_id, bufnr, request_id, request)
    elseif request.type == 'cancel' then
      -- do something with pending cancel requests
      track_canceling(client_id, bufnr, request_id, request)
    elseif request.type == 'complete' then
      -- do something with finished requests. this pending
      -- request entry is about to be removed since it is complete
      track_finish(client_id, bufnr, request_id, request)
    end
  end,
})
```

LspTokenUpdate LspTokenUpdate

When a visible semantic token is sent or updated by the LSP server, or when an existing token becomes visible for the first time. The autocmd-pattern is the buffer name. The event-data (type: `vim.event.lsptokenupdate.data`) has the client ID and token (see vim.lsp.semantic_tokens.get_at_pos()).

Example:

```
vim.api.nvim_create_autocmd('LspTokenUpdate', {
  callback = function(ev)
    local token = ev.data.token
    if token.type == 'variable' and not token.modifiers.readonly then
      vim.lsp.semantic_tokens.highlight_token(
        token, ev.buf, ev.data.client_id, 'MyMutableVariableHighlight'
      )
    end
  end,
})
```

Note: doing anything other than calling vim.lsp.semantic_tokens.highlight_token() is considered experimental.

Lua module: vim.lsp lsp-core

vim.lsp.Config Extends: vim.lsp.ClientConfig

Fields:

- `{cmd}?` (`string[]|fun(dispatchers: vim.lsp.rpc.Dispatchers, config: vim.lsp.ClientConfig): vim.lsp.rpc.Client`) See `cmd` in vim.lsp.ClientConfig. See also `reuse_client` to dynamically decide (per-buffer) when `cmd` should be re-invoked.
- `{filetypes}?` (`string[]`) Filetypes the client will attach to, or `nil` for ALL filetypes. To match files by name, pattern, or contents, you can define a custom filetype using vim.filetype.add():

  ```
  vim.filetype.add({
    filename = {
      ['my_filename'] = 'my_filetype1',
    },
    pattern = {
      ['.*/etc/my_file_pattern/.*'] = 'my_filetype2',
    },
  })
  vim.lsp.config('…', {
    filetypes = { 'my_filetype1', 'my_filetype2' },
  })
  ```

- `{reuse_client}?` (`fun(client: vim.lsp.Client, config: vim.lsp.ClientConfig, bufnr: integer): boolean`) Predicate which decides if a client should be re-used. Used on all running clients. The default implementation re-uses a client if name and root_dir matches.
- `{root_dir}?` (`string|fun(bufnr: integer, on_dir:fun(root_dir?:string))`) lsp-root_dir() Decides the workspace root: the directory where the LSP server will base its workspaceFolders, rootUri, and rootPath on initialization. The function form must call the `on_dir` callback to provide the root dir, or LSP will not be activated for the buffer. Thus a `root_dir()` function can dynamically decide per-buffer whether to activate (or skip) LSP. See example at vim.lsp.enable().
- `{root_markers}?` (`((string|string[])[])`) lsp-root_markers
  Filename(s) ("".git/"", ""package.json"", …) used to decide the workspace root. Unused if `root_dir` is defined. The list order decides priority. To indicate "equal priority", specify names in a nested list `{ { 'a.txt', 'b.lua' }, ... }`.
  - For each item, Nvim will search upwards (from the buffer file) for that marker, or list of markers; search stops at the first directory containing that marker, and the directory is used as the root dir (workspace folder).
  - Example: Find the first ancestor directory containing file or directory "stylua.toml"; if not found, find the first ancestor containing ".git":

```
root_markers = { 'stylua.toml', '.git' }
```

- Example: Find the first ancestor directory containing EITHER "stylua.toml" or ".luarc.json"; if not found, find the first ancestor containing ".git":

```
root_markers = { { 'stylua.toml', '.luarc.json' }, '.git' }
```

buf_attach_client({bufnr}, {client_id}) vim.lsp.buf_attach_client()
Implements the `textDocument/did…` notifications required to track a buffer for any language server.

Without calling this, the server won't be notified of changes to a buffer.

Parameters:
- {bufnr} (integer) Buffer handle, or 0 for current
- {client_id} (integer) Client id

Return:
(boolean) success `true` if client was attached successfully; `false` otherwise

buf_detach_client({bufnr}, {client_id}) vim.lsp.buf_detach_client()
Detaches client from the specified buffer. **Note:** While the server is notified that the text document (buffer) was closed, it is still able to send notifications should it ignore this notification.

Parameters:
- {bufnr} (integer) Buffer handle, or 0 for current
- {client_id} (integer) Client id

buf_is_attached({bufnr}, {client_id}) vim.lsp.buf_is_attached()
Checks if a buffer is attached for a particular client.

Parameters:
- {bufnr} (integer) Buffer handle, or 0 for current
- {client_id} (integer) the client id

buf_notify({bufnr}, {method}, {params}) vim.lsp.buf_notify()
Send a notification to a server

Attributes:
Since: 0.5.0

Parameters:
- {bufnr} (integer?) The number of the buffer
- {method} (string) Name of the request method
- {params} (any) Arguments to send to the server

Return:
(boolean) success true if any client returns true; false otherwise

vim.lsp.buf_request_all()
buf_request_all({bufnr}, {method}, {params}, {handler}) Sends an async request for all active clients attached to the buffer and executes the `handler` callback with the combined result.

Attributes:
Since: 0.5.0

Parameters:
- {bufnr} (integer) Buffer handle, or 0 for current.
- {method} (string) LSP method name
- {params} (table|(fun(client: vim.lsp.Client, bufnr: integer): table?)?) Parameters to send to the server. Can also be passed as a function that returns the params table for cases where parameters are specific to the client.
- {handler} (function) Handler called after all requests are completed. Server results are passed as a `client_id:result` map.

Return:
(function) cancel Function that cancels all requests.

vim.lsp.buf_request_sync()
buf_request_sync({bufnr}, {method}, {params}, {timeout_ms}) Sends a request to all server and waits for the response of all of them.

Calls vim.lsp.buf_request_all() but blocks Nvim while awaiting the result. Parameters are the same as vim.lsp.buf_request_all() but the result is different. Waits a maximum of {timeout_ms}.

Attributes:
Since: 0.5.0

Parameters:
- {bufnr} (integer) Buffer handle, or 0 for current.
- {method} (string) LSP method name
- {params} (table|(fun(client: vim.lsp.Client, bufnr: integer): table?)?) Parameters to send to the server. Can also be passed as a function that returns the params table for cases where parameters are specific to the client.
- {timeout_ms} (integer?, default: 1000) Maximum time in milliseconds to wait for a result.

Return (multiple):
(table<integer, {error: lsp.ResponseError?, result: any}>?) result Map of client_id:request_result. (string?) err On timeout, cancel, or error, `err` is a string describing the failure reason, and `result` is nil.

commands vim.lsp.commands
Map of client-defined handlers implementing custom (off-spec) commands which a server may invoke. Each key is a unique command name; each value is a function which is called when an LSP action (code action, code lenses, …) requests it by name.

If an LSP response requests a command not defined client-side, Nvim will forward it to the server as `workspace/executeCommand`.

- Argument 1 is the `Command`:

```
Command
title: String
command: String
arguments?: any[]
```

- Argument 2 is the lsp-handler `ctx`.

Example:

```
vim.lsp.commands['java.action.generateToStringPrompt'] = function(_, ctx)
  require("jdtls.async").run(function()
    local _, result = request(ctx.bufnr, 'java/checkToStringStatus', ctx.params)
    local fields = ui.pick_many(result.fields, 'Include item in toString?', function(x)
      return string.format('%s: %s', x.name, x.type)
    end)
    local _, edit = request(ctx.bufnr, 'java/generateToString', { context = ctx.params; fields = fields; })
    vim.lsp.util.apply_workspace_edit(edit, offset_encoding)
  end)
end
```

config({name}, {cfg}) vim.lsp.config()
Sets the default configuration for an LSP client (or all clients if the special name "*" is used).

Can also be accessed by table-indexing (`vim.lsp.config[…]`) to get the resolved config, or redefine the config (instead of "merging" with the config chain).

Examples:
- Add root markers for ALL clients:

```
vim.lsp.config('*', {
  root_markers = { '.git', '.hg' },
})
```

- Add capabilities to ALL clients:

```
  vim.lsp.config('*', {
  capabilities = {
    textDocument = {
      semanticTokens = {
        multilineTokenSupport = true,
      }
    }
  }
})
```

- Add root markers and capabilities for "clangd":

```
  vim.lsp.config('clangd', {
  root_markers = { '.clang-format', 'compile_commands.json' },
  capabilities = {
    textDocument = {
      completion = {
        completionItem = {
          snippetSupport = true,
        }
      }
    }
  }
})
```

- (Re-)define the "clangd" configuration (overrides the resolved chain):

```
  vim.lsp.config.clangd = {
  cmd = {
    'clangd',
    '--clang-tidy',
    '--background-index',
    '--offset-encoding=utf-8',
  },
  root_markers = { '.clangd', 'compile_commands.json' },
  filetypes = { 'c', 'cpp' },
}
```

- Get the resolved configuration for "emmylua_ls":

```
local cfg = vim.lsp.config.emmylua_ls
```

Attributes:
Since: 0.11.0

Parameters:
- `{name}` (`string`)
- `{cfg}` (`vim.lsp.Config`)

enable({name}, {enable}) vim.lsp.enable()
Enables a lsp-config: automatically attaches the client to any buffer based on the config `filetypes`, `root_markers`, and `root_dir`. See lsp-activate for details.

To disable, pass `enable=false`: Stops related clients and servers (force-stops servers after a timeout, unless `exit_timeout=false`).

Raises an error under the following conditions:
- {name} is not a valid LSP config name (for example, `'*'`).
- {name} corresponds to an LSP config file which raises an error.

If an error is raised when multiple names are provided, this function will have no side-effects; it will not enable/disable any configs, including ones which contain no errors.

Examples:

```
vim.lsp.enable('clangd')
vim.lsp.enable({'emmylua_ls', 'pyright'})
```

Example: To dynamically decide whether LSP is activated, define a lsp-root_dir() function which calls `on_dir()` only when you want that config to activate:

```
vim.lsp.config('emmylua_ls', {
  root_dir = function(bufnr, on_dir)
    if vim.fs.ext(vim.fn.bufname(bufnr)) ~= 'txt' then
      on_dir(vim.fn.getcwd())
    end
  end
})
```

Attributes:
Since: 0.11.0

Parameters:
- {name} (`string|string[]`) Name(s) of client(s) to enable.
- {enable} (`boolean?`) If `true|nil`, enables auto-activation of the given LSP config on current and future buffers. If `false`, disables auto-activation and stops related LSP clients and servers (force-stops servers after `exit_timeout` milliseconds).

foldclose({kind}, {winid}) vim.lsp.foldclose()
Close all {kind} of folds in the window with {winid}.

To automatically fold imports when opening a file, you can use an autocmd:

```
vim.api.nvim_create_autocmd('LspNotify', {
  callback = function(ev)
    if ev.data.method == 'textDocument/didOpen' then
      vim.lsp.foldclose('imports', vim.fn.bufwinid(ev.buf))
    end
  end,
})
```

Attributes:
Since: 0.11.0

Parameters:
- {kind} (`lsp.FoldingRangeKind`) Kind to close, one of "comment", "imports" or "region".
- {winid} (`integer?`) Defaults to the current window.

foldexpr({lnum}) vim.lsp.foldexpr()
Provides an interface between the built-in client and a `foldexpr` function.

To use, set 'foldmethod' to "expr" and set the value of 'foldexpr':

```
vim.o.foldmethod = 'expr'
vim.o.foldexpr = vim.lsp.foldexpr
```

Or use it only when supported by checking for the "textDocument/foldingRange" capability in an LspAttach autocommand. Example:

```
vim.o.foldmethod = 'expr'
-- Default to treesitter folding
vim.o.foldexpr = vim.treesitter.foldexpr
-- Prefer LSP folding if client supports it
vim.api.nvim_create_autocmd('LspAttach', {
  callback = function(ev)
    local client = vim.lsp.get_client_by_id(ev.data.client_id)
    if client:supports_method('textDocument/foldingRange') then
      local win = vim.api.nvim_get_current_win()
      vim.wo[win][0].foldexpr = vim.lsp.foldexpr
    end
  end,
})
```

Parameters:
- {lnum} (`integer`) line number

foldtext({lnum}) vim.lsp.foldtext()
Provides a `foldtext` function that shows the `collapsedText` retrieved, defaults to the first folded line if `collapsedText` is not provided.

The displayed foldtext will be highlighted via treesitter.

Parameters:
- {lnum} (`integer?`) line number (default: current fold start)

formatexpr({opts}) vim.lsp.formatexpr()
Provides an interface between the built-in client and a `formatexpr` function.

Currently only supports a single client. This can be set via `vim.bo[bufnr].formatexpr = vim.lsp.formatexpr`, or with a wrapper to pass options:

```
vim.bo[bufnr].formatexpr = function()
  return vim.lsp.formatexpr({ timeout_ms = 250 })
end
```

Parameters:
- `{opts}` (`table?`) A table with the following fields:
  - `{timeout_ms}?` (`integer`, default: 500ms) The timeout period for the formatting request..

get_client_by_id({client_id}) vim.lsp.get_client_by_id()
Gets a client by id, or nil if the id is invalid or the client was stopped. The returned client may not yet be fully initialized.

Parameters:
- `{client_id}` (`integer`) client id

Return:
(`vim.lsp.Client?`) client rpc object

get_clients({filter}) vim.lsp.get_clients()
Gets active clients.

Attributes:
Since: 0.10.0

Parameters:
- `{filter}` (`table?`) Key-value pairs used to filter the returned clients.
  - `{bufnr}?` (`integer`) Only return clients attached to this buffer
  - `{id}?` (`integer`) Only return clients with the given id
  - `{method}?` (`string`) Only return clients supporting the given method
  - `{name}?` (`string`) Only return clients with the given name

Return:
(`vim.lsp.Client[]`) List of vim.lsp.Client objects

get_configs({filter}) vim.lsp.get_configs()
Gets LSP configs.

See also vim.lsp.get_clients() to get the runtime values of dynamic fields like `root_dir`, which depend on the current buffer/workspace/etc.

WARNING: May eagerly (prematurely!) evaluate config files in 'runtimepath'.

Attributes:
Since: 0.12.0

Parameters:
- `{filter}` (`table?`) Key-value pairs used to filter the returned configs.
  - `{enabled}?` (`boolean`) If true, only return enabled configs. If false, only return configs that aren't enabled.
  - `{filetype}?` (`string`) Only return configs which attach to the given filetype.

Return:
(`vim.lsp.Config[]`) List of vim.lsp.Config objects

is_enabled({name}) vim.lsp.is_enabled()
Checks if the given LSP config is enabled (globally, not per-buffer).

Unlike `vim.lsp.config['…']`, this does not have the side-effect of resolving the config.

Parameters:
- `{name}` (`string`) Config name

Return:
(`boolean`)

omnifunc({findstart}, {base}) vim.lsp.omnifunc()
Implements 'omnifunc' compatible LSP completion.

Parameters:
- `{findstart}` (`integer`) 0 or 1, decides behavior
- `{base}` (`integer`) findstart=0, text to match against

Return:
(`integer|table`) Decided by `{findstart}`:
- findstart=1: column where the completion starts, or -2 or -3
- findstart=0: list of matches (actually just calls complete())

See also:
- complete-functions
- complete-items
- CompleteDone

start({config}, {opts}) vim.lsp.start()
Create a new LSP client and start a language server or reuses an already running client if one is found matching `name` and `root_dir`. Attaches the current buffer to the client.

Example:

```
vim.lsp.start({
   name = 'my-server-name',
   cmd = {'name-of-language-server-executable'},
   root_dir = vim.fs.root(0, {'pyproject.toml', 'setup.py'}),
})
```

See vim.lsp.ClientConfig for all available options. The most important are:

- `name` arbitrary name for the LSP client. Should be unique per language server.
- `cmd` command string[] or function. See also lsp-server.
- `root_dir` path to the project root. By default this is used to decide if an existing client should be re-used. The example above uses vim.fs.root() to detect the root by traversing the file system upwards starting from the current directory until either a `pyproject.toml` or `setup.py` file is found.
- `workspace_folders` list of `{ uri:string, name: string }` tables specifying the project root folders used by the language server. If `nil` the property is derived from `root_dir` for convenience.

Language servers use this information to discover metadata like the dependencies of your project and they tend to index the contents within the project folder.

To ensure a language server is only started for languages it can handle, make sure to call vim.lsp.start() within a FileType autocmd. Either use :au, nvim_create_autocmd() or put the call in a `ftplugin/<filetype_name>.lua` (See ftplugin-name)

Attributes:
Since: 0.8.0

Parameters:

- `{config}` (`vim.lsp.ClientConfig`) Configuration for the server.
- `{opts}` (`table?`) Optional keyword arguments.
  - `{attach}?` (`boolean`, default: true) Whether to attach the client to a buffer. If set to `false`, `reuse_client` and `bufnr` will be ignored.
  - `{bufnr}?` (`integer`) Buffer handle to attach to if starting or re-using a client (0 for current).
  - `{reuse_client}?` (`fun(client: vim.lsp.Client, config: vim.lsp.ClientConfig, bufnr: integer): boolean`) Predicate used to decide if a client should be re-used. Used on all running clients. The default implementation re-uses a client if it has the same name and if the given workspace folders (or root_dir) are all included in the client's workspace folders.
  - `{silent}?` (`boolean`, default: false) Suppress error reporting if the LSP server fails to start.

Return:
(`integer?`) client_id

status() vim.lsp.status()
Consumes the latest progress messages from all clients and formats them as a string. Empty if there are no clients or if no new messages

Return:
(`string`)

tagfunc({`pattern`}, {`flags`}) vim.lsp.tagfunc()
Provides an interface between the built-in client and 'tagfunc'.

When used with normal mode commands (e.g. CTRL-]) this will invoke the "textDocument/definition" LSP method to find the tag under the cursor. Otherwise, uses "workspace/symbol". If no results are returned from any LSP servers, falls back to using built-in tags.

Parameters:

- `{pattern}` (`string`) Pattern used to find a workspace symbol
- `{flags}` (`string`) See tag-function

Return:
(`table[]|vim.NIL`) tags A list of matching tags, or `vim.NIL` to use the built-in tags.

Lua module: vim.lsp.buf lsp-buf

The `vim.lsp.buf_…` functions perform operations for LSP clients attached to the current buffer.

vim.lsp.ListOpts

Fields:

- `{loclist}?` (`boolean`) Whether to use the location-list or the quickfix list in the default handler.

```
vim.lsp.buf.definition({ loclist = true })
vim.lsp.buf.references(nil, { loclist = false })
```

- `{on_list}?` (`fun(what: vim.fn.setqflist.what)`) list-handler replacing the default handler. Called for any non-empty result. The default handler populates the quickfix (or location) list with the result. If there is a single result (and the method is not `implementation` or `references`), it pushes a tag onto the tagstack and jumps to the result. For example, when `loclist == false` (the default), the handler is equivalent to:

```
local function on_list(what)
  vim.fn.setqflist({}, ' ', what)
  if
    #what.items == 1
    and what.context.method ~= 'textDocument/implementation'
    and what.context.method ~= 'textDocument/references'
  then
    local tagstack = { { tagname = tagname, from = from } }
    vim.fn.settagstack(vim.fn.win_getid(win), { items = tagstack }, 't')
    vim.cmd('cfirst')
  else
    vim.cmd('botright copen')
  end
end

vim.lsp.buf.definition({ on_list = on_list })
vim.lsp.buf.references(nil, { on_list = on_list })
```

The list can be transformed before it is shown. For example, to remove duplicate locations returned by multiple clients:

```
local function on_list(what)
  vim.list.unique(what.items, function(item)
    return ('%s\0%d\0%d\0%d\0%d'):format(
      item.filename or '',
      item.lnum or 0,
      item.col or 0,
      item.end_lnum or 0,
      item.end_col or 0
    )
  end)
  vim.fn.setqflist({}, ' ', what)
  vim.cmd('botright copen')
end

vim.lsp.buf.definition({ on_list = on_list })
vim.lsp.buf.references(nil, { on_list = on_list })
```

See setqflist-what for the structure of the `what` parameter.

- `{pos}`? (`vim.Pos`, default: cursor position) Position on a buffer to request.

vim.lsp.buf.hover.Opts Extends: vim.lsp.util.open_floating_preview.Opts

Fields:

- `{silent}`? (`boolean`)

vim.lsp.buf.signature_help.Opts Extends: vim.lsp.util.open_floating_preview.Opts

Fields:

- `{silent}`? (`boolean`)

vim.lsp.buf.add_workspace_folder()

add_workspace_folder(`{workspace_folder}`) Add the folder at path to the workspace folders. If `{path}` is not provided, the user will be prompted for a path using input().

Parameters:

- `{workspace_folder}` (`string?`)

clear_references() vim.lsp.buf.clear_references()

Removes document highlights from current buffer.

code_action(`{opts}`) vim.lsp.buf.code_action()

Selects a code action (LSP: "textDocument/codeAction" request) available at cursor position.

Parameters:

- `{opts}` (`table?`) A table with the following fields:
  - `{apply}`? (`boolean`) When set to `true`, and there is just one remaining action (after filtering), the action is applied without user query.
  - `{context}`? (`table`) Corresponds to `lsp.CodeActionContext`, but all fields are optional:
    - `{diagnostics}`? (`lsp.Diagnostic[]`) Inferred from the current position if not provided.
    - `{only}`? (`lsp.CodeActionKind[]`) `CodeActionKinds` used to filter the code actions. Most servers support values like "refactor" or "quickfix".
    - `{triggerKind}`? (`lsp.CodeActionTriggerKind`) Why code actions were requested.
  - `{filter}`? (`fun(x: lsp.CodeAction|lsp.Command, client_id: integer):boolean`) Predicate taking a code action or command and the provider's ID. If it returns false, the action is filtered out.
  - `{range}`? (`{start: integer[], end: integer[]}`) Range for which code actions should be requested. If in visual mode this defaults to the active selection. Table must contain `start` and `end` keys with `{row,col}` tuples using mark-like indexing. See api-indexing

See also:

- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocument_codeAction
- vim.lsp.protocol.CodeActionTriggerKind

declaration(`{opts}`) vim.lsp.buf.declaration()

Jumps to the declaration of the symbol under the cursor.

Note:

- Many servers do not implement this method. Generally, see vim.lsp.buf.definition() instead.

Parameters:

- `{opts}` (`vim.lsp.ListOpts?`)

definition({opts}) vim.lsp.buf.definition()
Jumps to the definition of the symbol under the cursor.

Parameters:
- {opts} (vim.lsp.ListOpts?)

document_highlight() vim.lsp.buf.document_highlight()
Send request to the server to resolve document highlights for the current text document position. This request can be triggered by a key mapping or by events such as CursorHold, e.g.:

```
autocmd CursorHold  <buffer> lua vim.lsp.buf.document_highlight()
autocmd CursorHoldI <buffer> lua vim.lsp.buf.document_highlight()
autocmd CursorMoved <buffer> lua vim.lsp.buf.clear_references()
```

Note: Usage of vim.lsp.buf.document_highlight() requires the following highlight groups to be defined or you won't be able to see the actual highlights. hl-LspReferenceText hl-LspReferenceRead hl-LspReferenceWrite

document_symbol({opts}) vim.lsp.buf.document_symbol()
Lists all symbols in the current buffer in the location-list.

Parameters:
- {opts} (vim.lsp.ListOpts?)

format({opts}) vim.lsp.buf.format()
Formats a buffer using the attached (and optionally filtered) language server clients.

Parameters:
- {opts} (table?) A table with the following fields:
  - {async}? (boolean, default: false) If true the method won't block. Editing the buffer while formatting asynchronous can lead to unexpected changes.
  - {bufnr}? (integer, default: current buffer) Restrict formatting to the clients attached to the given buffer.
  - {filter}? (fun(client: vim.lsp.Client): boolean?) Predicate used to filter clients. Receives a client as argument and must return a boolean. Clients matching the predicate are included. Example:

    ```
    -- Never request typescript-language-server for formatting
    vim.lsp.buf.format {
      filter = function(client) return client.name ~= "ts_ls" end
    }
    ```

  - {formatting_options}? (lsp.FormattingOptions) Can be used to specify FormattingOptions. Some unspecified options will be automatically derived from the current Nvim options. See https://microsoft.github.io/language-server-protocol/specification/#formattingOptions
  - {id}? (integer) Restrict formatting to the client with ID (client.id) matching this field.
  - {name}? (string) Restrict formatting to the client with name (client.name) matching this field.
  - {range}? ({start:[integer,integer],end:[integer, integer]}|{start:[integer,integer],end:[integer,integer]}[], default: current selection in visual mode, nil in other modes, formatting the full buffer) Range to format. Table must contain start and end keys with {row,col} tuples using (1,0) indexing. The end column can be -1 to format through the end of the line. Can also be a list of tables that contain start and end keys as described above, in which case textDocument/rangesFormatting support is required.
  - {timeout_ms}? (integer, default: 1000 for synchronous requests) Time in milliseconds allowed for each formatting request. On timeout, cancels the request and continues with the next client. With async=true, there is no timeout unless this option is set. Responses received after the request times out are ignored.

hover({config}) vim.lsp.buf.hover()
Displays hover information about the symbol under the cursor in a floating window. The window will be dismissed on cursor move. Calling the function twice will jump into the floating window (thus by default, "KK" will open the hover window and focus it). In the floating window, all commands and mappings are available as usual, except that "q" dismisses the window. You can scroll the contents the same as you would any other buffer.

Note: to disable hover highlights, add the following to your config:

```
vim.api.nvim_create_autocmd('ColorScheme', {
  callback = function()
    vim.api.nvim_set_hl(0, 'LspReferenceTarget', {})
  end,
})
```

Parameters:
- {config} (vim.lsp.buf.hover.Opts?)

implementation({opts}) vim.lsp.buf.implementation()
Lists all the implementations for the symbol under the cursor in the quickfix window.

Parameters:
- {opts} (vim.lsp.ListOpts?)

incoming_calls() vim.lsp.buf.incoming_calls()
Lists all the call sites of the symbol under the cursor in the quickfix window. If the symbol can resolve to multiple items, the user can pick one in the inputlist().

list_workspace_folders() vim.lsp.buf.list_workspace_folders()
List workspace folders.

outgoing_calls() vim.lsp.buf.outgoing_calls()
Lists all the items that are called by the symbol under the cursor in the quickfix window. If the symbol can resolve to multiple items, the user can pick one in the inputlist().

references({context}, {opts}) vim.lsp.buf.references()
Lists all the references to the symbol under the cursor in the quickfix window.

Parameters:
- {context} (lsp.ReferenceContext?) Context for the request
- {opts} (vim.lsp.ListOpts?)

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocument_references

vim.lsp.buf.remove_workspace_folder()
remove_workspace_folder({workspace_folder}) Remove the folder at path from the workspace folders. If {path} is not provided, the user will be prompted for a path using input().

Parameters:
- {workspace_folder} (string?)

rename({new_name}, {opts}) vim.lsp.buf.rename()
Renames all references to the symbol under the cursor.

Parameters:
- {new_name} (string?) If not provided, the user will be prompted for a new name using vim.ui.input().
- {opts} (table?) Additional options:
  - {bufnr}? (integer) (default: current buffer)
  - {filter}? (fun(client: vim.lsp.Client): boolean?) Predicate used to filter clients. Receives a client as argument and must return a boolean. Clients matching the predicate are included.
  - {name}? (string) Restrict clients used for rename to ones where client.name matches this field.

vim.lsp.buf.selection_range()
selection_range({direction}, {timeout_ms}) lsp-incremental-selection

Expands or contracts a Visual selection at cursor, based on ranges given by LSP. The direction parameter specifies the number of times to expand the selection. Negative values will shrink the selection.

Parameters:
- {direction} (integer)
- {timeout_ms} (integer?) (default: 1000) Maximum time (milliseconds) to wait for a result.

signature_help({config}) vim.lsp.buf.signature_help()
Displays signature information about the symbol under the cursor in a floating window. Allows cycling through signature overloads with <C-s>, which can be remapped via <Plug>(nvim.lsp.ctrl-s)

Example:

```
vim.keymap.set('n', '<C-b>', '<Plug>(nvim.lsp.ctrl-s)')
```

Parameters:
- {config} (vim.lsp.buf.signature_help.Opts?)

type_definition({opts}) vim.lsp.buf.type_definition()
Jumps to the definition of the type of the symbol under the cursor.

Parameters:
- {opts} (vim.lsp.ListOpts?)

typehierarchy({kind}) vim.lsp.buf.typehierarchy()
Lists all the subtypes or supertypes of the symbol under the cursor in the quickfix window. If the symbol can resolve to multiple items, the user can pick one using vim.ui.select().

Parameters:
- {kind} ("subtypes"|"supertypes")

workspace_diagnostics({opts}) vim.lsp.buf.workspace_diagnostics()
Request workspace-wide diagnostics.

Parameters:
- {opts} (table?) A table with the following fields:
  - {client_id}? (integer) Only request diagnostics from the indicated client. If nil, the request is sent to all clients.

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#workspace_diagnostic

workspace_symbol({query}, {opts}) vim.lsp.buf.workspace_symbol()
Lists all symbols in the current workspace in the quickfix window.

The list is filtered against {query}; if the argument is omitted from the call, the user is prompted to enter a string on the command line. An empty string means no filtering is done.

Parameters:
- {query} (string?) optional
- {opts} (vim.lsp.ListOpts?)

Lua module: vim.lsp.client lsp-client

vim.lsp.Client

Fields:
- {attached_buffers} (table<integer,string>) Each buffer's last used languageId.
- {cancel_request} (fun(self: vim.lsp.Client, id: integer): boolean) See Client:cancel_request().

- {capabilities} (lsp.ClientCapabilities) Capabilities provided by the client (editor or tool), at startup.
- {commands} (table<string,fun(command: lsp.Command, ctx: table)>) Client commands. See vim.lsp.ClientConfig.
- {config} (vim.lsp.ClientConfig) Copy of the config passed to vim.lsp.start().
- {dynamic_capabilities} (lsp.DynamicCapabilities) Capabilities provided at runtime (after startup).
- {exec_cmd} (fun(self: vim.lsp.Client, cmd: lsp.Command, context: {bufnr?: integer}?, handler: lsp.Handler?)) See Client:exec_cmd().
- {exit_timeout} (integer|boolean, default: false) See vim.lsp.ClientConfig.
- {flags} (table) Experimental client flags:
  - {allow_incremental_sync}? (boolean, default: true) Allow using incremental sync for buffer edits
  - {debounce_text_changes}? (integer, default: 150) Debounce didChange notifications to the server by the given number in milliseconds.
- {get_language_id} (fun(bufnr: integer, filetype: string): string) See vim.lsp.ClientConfig.
- {handlers} (table<string,lsp.Handler>) See vim.lsp.ClientConfig.
- {id} (integer) The id allocated to the client.
- {initialized} (true?)
- {is_stopped} (fun(self: vim.lsp.Client): boolean) See Client:is_stopped().
- {name} (string) See vim.lsp.ClientConfig.
- {notify} (fun(self: vim.lsp.Client, method: string, params: table?, bufnr: integer?): boolean) See Client:notify().
- {offset_encoding} ('utf-8'|'utf-16'|'utf-32') See vim.lsp.ClientConfig.
- {on_attach} (fun(self: vim.lsp.Client, bufnr: integer)) See Client:on_attach().
- {progress} (vim.lsp.Client.Progress) A ring buffer (vim.ringbuf()) containing progress messages sent by the server.
- {request} (fun(self: vim.lsp.Client, method: string, params: table?, handler: lsp.Handler?, bufnr: integer?): boolean, integer?) See Client:request().
- {request_sync} (fun(self: vim.lsp.Client, method: string, params: table, timeout_ms: integer?, bufnr: integer?): {err: lsp.ResponseError?, result:any}?, string?) See Client:request_sync().
- {requests} (table<integer,{ type: string, bufnr: integer, method: vim.lsp.protocol.Method}?>) The current pending requests in flight to the server. Entries are key-value pairs with the key being the request id while the value is a table with type, bufnr, and method key-value pairs. type is either "pending" for an active request, or "cancel" for a cancel request. It will be "complete" ephemerally while executing LspRequest autocmds when replies are received from the server.
- {root_dir} (string?) See vim.lsp.ClientConfig.
- {rpc} (vim.lsp.rpc.Client) RPC client object, for low level interaction with the client. See vim.lsp.rpc.start().
- {server_capabilities} (lsp.ServerCapabilities) Response from the server sent on initialize describing the server's capabilities.
- {server_info} (lsp.ServerInfo?) Response from the server sent on initialize describing server information (e.g. version).
- {settings} (lsp.LSPObject) See vim.lsp.ClientConfig.
- {stop} (fun(self: vim.lsp.Client, force: integer|boolean?)) See Client:stop().
- {supports_method} (fun(self: vim.lsp.Client, method: string|string, bufnr: integer?): boolean) See Client:supports_method().
- {workspace_folders} (lsp.WorkspaceFolder[]?) See vim.lsp.ClientConfig.

vim.lsp.Client.Progress Extends: vim.Ringbuf

Fields:
- {pending} (table<lsp.ProgressToken,lsp.LSPAny>)

vim.lsp.ClientConfig

Fields:
- {before_init}? (fun(params: lsp.InitializeParams, config: vim.lsp.ClientConfig)) Callback which can modify parameters before they are sent to the server. Invoked before LSP "initialize" phase (after cmd is invoked), where params is the parameters being sent to the server and config is the config passed to vim.lsp.start().

Hint: use vim.tbl_deep_extend() to set nested fields easily.

```
before_init = function(_, config)
  config.settings = vim.tbl_deep_extend('force',
    config.settings,
    { tailwindCSS = { experimental = { configFile = find_tailwind_global_css() } } }
  )
end
```

- {capabilities}? (lsp.ClientCapabilities) Map overriding the default capabilities defined by vim.lsp.protocol.make_client_capabilities(), passed to the language server on initialization. Hint: use make_client_capabilities() and modify its result.
  - **Note:** To send an empty dictionary use vim.empty_dict(), else it will be encoded as an array.
- {cmd} (string[]|fun(dispatchers: vim.lsp.rpc.Dispatchers, config: vim.lsp.ClientConfig): vim.lsp.rpc.Client) Command string[] that launches the language server (treated as in jobstart(), must be absolute or on $PATH, shell constructs like "~" are not expanded), or function that creates an RPC client (or an in-process lsp-server). Function receives a dispatchers table and the resolved config, and must return an object in the form of vim.lsp.rpc.Client.

Example (list):

```
cmd = { 'flow', 'lsp' }
```

Example (function):

```
cmd = function(dispatchers, config)
  local cmd = vim.fn.executable('flow') == 1 and { 'flow', 'lsp' } or { 'npx', '--no-install', 'flow', 'lsp' }
  return vim.lsp.rpc.start(cmd, dispatchers)
end
```

- See vim.lsp.rpc.Client.
- For TCP there is a builtin RPC client factory: vim.lsp.rpc.connect()

- {cmd_cwd}? (string) Directory where the cmd process is launched when cmd is a string array. Defaults to root_dir when available, then the current working directory.
- {cmd_env}? (table) Environment variables passed to the LSP process on spawn. Non-string values are coerced to string. Example:

```
{ PORT = 8080, HOST = '0.0.0.0' }
```

- {commands}? (table<string,fun(command: lsp.Command, ctx: table)>) Map of client-defined commands overriding the global vim.lsp.commands.
- {detached}? (boolean, default: true) Daemonize the server process so that it runs in a separate process group from Nvim. Nvim will shutdown the process on exit, but if Nvim fails to exit cleanly this could leave behind orphaned server processes.
- {exit_timeout}? (integer|boolean, default: false) Decides if/when to force-stop the server after sending the "shutdown" request. See Client:stop(). **Note:** when Nvim itself is exiting,
  - false: Nvim will not force-stop LSP server(s).
  - true: Nvim will force-stop LSP server(s) that did not comply with the "shutdown" request.
  - number: Nvim will wait up to exit_timeout milliseconds before performing force-stop.
- {flags}? (table) Experimental client flags:
  - {allow_incremental_sync}? (boolean, default: true) Allow using incremental sync for buffer edits
  - {debounce_text_changes}? (integer, default: 150) Debounce didChange notifications to the server by the given number in milliseconds.
- {get_language_id}? (fun(bufnr: integer, filetype: string): string) Language ID as string. Defaults to the buffer filetype.
- {handlers}? (table<string,function>) Map of LSP method names to lsp-handlers.
- {init_options}? (lsp.LSPObject) Values to pass in the initialization request as initializationOptions. See initialize in the LSP spec.
- {name}? (string, default: client-id) Name in logs and user messages.
- {offset_encoding}? ('utf-8'|'utf-16'|'utf-32') Called "position encoding" in LSP spec. The encoding that the LSP server expects, used for communication. Not validated. Can be modified in on_init before text is sent to the server.
- {on_attach}? (elem_or_list<fun(client: vim.lsp.Client, bufnr: integer)>) Callback invoked when client attaches to a buffer.
- {on_error}? (fun(code: integer, err: string)) Callback invoked when the client operation throws an error. code is a number describing the error. Other arguments may be passed depending on the error kind. See vim.lsp.rpc.client_errors for possible errors. Use vim.lsp.rpc.client_errors[code] to get human-friendly name.
- {on_exit}? (elem_or_list<fun(code: integer, signal: integer, client_id: integer)>) Callback invoked on client exit.
  - code: exit code of the process
  - signal: number describing the signal used to terminate (if any)
  - client_id: client handle
- {on_init}? (elem_or_list<fun(client: vim.lsp.Client, init_result: lsp.InitializeResult)>) Callback invoked after LSP "initialize", where result is a table of capabilities and anything else the server may send. For example, clangd sends init_result.offsetEncoding if capabilities.offsetEncoding was sent to it. You can only modify the client.offset_encoding here before any notifications are sent.
- {root_dir}? (string) Directory where the LSP server will base its workspaceFolders, rootUri, and rootPath on initialization.
- {settings}? (lsp.LSPObject) Map of language server-specific settings, decided by the client. Sent to the LS if requested via workspace/configuration. Keys are case-sensitive.
- {trace}? ('off'|'messages'|'verbose', default: "off") Passed directly to the language server in the initialize request. Invalid/empty values will
- {workspace_folders}? (lsp.WorkspaceFolder[]) List of workspace folders passed to the language server. For backwards compatibility rootUri and rootPath are derived from the first workspace folder in this list. Can be null if the client supports workspace folders but none are configured. See workspaceFolders in LSP spec.
- {workspace_required}? (boolean, default: false) Server requires a workspace (no "single file" support). **Note:** Without a workspace, cross-file features (navigation, hover) may or may not work depending on the language server, even if the server doesn't require a workspace.

Client:cancel_request({id}) Client:cancel_request()
Cancels a request with a given request id.

Parameters:
- {id} (integer) id of request to cancel

Return:
(boolean) status indicating if the notification was successful.

See also:
- Client:notify()

Client:exec_cmd({cmd}, {context}, {handler}) Client:exec_cmd()
Execute a lsp command, either via client command function (if available) or via workspace/executeCommand (if supported by the server)

Parameters:
- {cmd} (lsp.Command)
- {context} ({bufnr?: integer}?)
- {handler} (lsp.Handler?) only called if a server command

Client:is_stopped() Client:is_stopped()
Checks whether a client is stopped.

Return:
(boolean) true if client is stopped or in the process of being stopped; false otherwise

Client:notify({method}, {params}, {bufnr}) Client:notify()
Sends a notification to an LSP server.

Parameters:
- {method} (string) LSP method name.
- {params} (table?) LSP request params.
- {bufnr} (integer?) Buffer associated with notification.

Return:
(boolean) status indicating if the notification was successful. If it is false, then the client has shutdown.

Client:on_attach({bufnr}) Client:on_attach()
Runs the on_attach function from the client's config if it was defined. Useful for buffer-local setup.

Parameters:
- {bufnr} (integer) Buffer number

Client:request()

Client:request({method}, {params}, {handler}, {bufnr}) Sends a request to the server.

This is a thin wrapper around {client.rpc.request} with some additional checks for capabilities and handler availability.

Parameters:
- {method} (string) LSP method name.
- {params} (table?) LSP request params.
- {handler} (lsp.Handler?) Response lsp-handler for this method.
- {bufnr} (integer?) (default: 0) Buffer handle, or 0 for current.

Return (multiple):
(boolean) status indicates whether the request was successful. If it is false, then it will always be false (the client has shutdown).
(integer?) request_id Can be used with Client:cancel_request(). nil is request failed.

See also:
- vim.lsp.buf_request_all()

Client:request_sync()

Client:request_sync({method}, {params}, {timeout_ms}, {bufnr}) Sends a request to the server and synchronously waits for the response.

This is a wrapper around Client:request()

Parameters:
- {method} (string) LSP method name.
- {params} (table) LSP request params.
- {timeout_ms} (integer?) Maximum time in milliseconds to wait for a result. Defaults to 1000
- {bufnr} (integer?) (default: 0) Buffer handle, or 0 for current.

Return (multiple):
({err: lsp.ResponseError?, result:any}?) result and err from the lsp-handler. nil is the request was unsuccessful (string?) err On timeout, cancel or error, where err is a string describing the failure reason.

See also:
- vim.lsp.buf_request_sync()

Client:stop({force}) Client:stop()
Stops a client, optionally with force after a timeout.

By default this sends a "shutdown" request to the server, escalating to force-stop if the server has not exited after self.exit_timeout milliseconds (unless exit_timeout=false). Calling stop() on a client that was previously requested to shutdown, will escalate to force-stop immediately, regardless of force (or self.exit_timeout if force=nil).

Note: Forcing shutdown while a server is busy writing out project or index files can lead to file corruption.

Parameters:
- {force} (integer|boolean?) (default: self.exit_timeout) Decides whether to force-stop the server.
  - false: Do not force-stop after "shutdown" request.
  - nil: Defaults to exit_timeout from vim.lsp.ClientConfig.
  - true: Force-stop after "shutdown" request.
  - number: Wait up to force milliseconds before force-stop.

Client:supports_method({method}, {bufnr}) Client:supports_method()
Checks if a client supports a given method. Always returns true for unknown off-spec methods.

Note: Some language server capabilities can be file specific.

Parameters:
- {method} (string|string)
- {bufnr} (integer?)

Return:
(boolean)

Lua module: vim.lsp.codelens lsp-codelens

enable({enable}, {filter}) vim.lsp.codelens.enable()
Enables or disables code lens for the {filter}ed scope.

To "toggle", pass the inverse of is_enabled():

```
vim.lsp.codelens.enable(not vim.lsp.codelens.is_enabled())
```

To run a code lens, see vim.lsp.codelens.run().

Parameters:
- {enable} (boolean?) true/nil to enable, false to disable
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

get({filter}) vim.lsp.codelens.get()
Get all code lenses in the {filter}ed scope.

Parameters:
- {filter} (table?) Optional filters kwargs:
  - {bufnr}? (integer, default: 0) Buffer handle, or 0 for current.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

Overloads:
- fun(filter: integer): lsp.CodeLens[]

Return:
(table[]) A list of objects with the following fields:
  - {client_id} (integer)
  - {lens} (lsp.CodeLens)

is_enabled({filter}) vim.lsp.codelens.is_enabled()
Query whether code lens is enabled in the {filter}ed scope

Parameters:
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

Return:
(boolean) whether code lens is enabled.

run({opts}) vim.lsp.codelens.run()
Run code lens at the current cursor position.

Parameters:
- {opts} (table?) Optional parameters kwargs:
  - {client_id}? (integer, default: all) Client ID, or nil for all.

Lua module: vim.lsp.completion lsp-completion

The vim.lsp.completion module enables insert-mode completion driven by an LSP server. Call enable() to make it available through Nvim builtin completion (via the CompleteDone event). Specify autotrigger=true to activate "auto-completion" when you type any of the server-defined triggerCharacters. Use CTRL-Y to select an item from the completion menu. complete_CTRL-Y

Example: activate LSP-driven auto-completion:

```
-- Works best if 'completeopt' has "noselect".
-- Use CTRL-Y to select an item. |complete_CTRL-Y|
vim.cmd[[set completeopt+=menuone,noselect,popup]]
vim.lsp.start({
  name = 'ts_ls',
  cmd = …,
  on_attach = function(client, bufnr)
    vim.lsp.completion.enable(true, client.id, bufnr, {
      autotrigger = true,
      convert = function(item)
        return { abbr = item.label:gsub('%b()', '') }
      end,
    })
  end,
})
```

lsp-autocompletion

The LSP triggerCharacters field decides when to trigger autocompletion. If you want to trigger on EVERY keypress you can either:
- Extend client.server_capabilities.completionProvider.triggerCharacters on LspAttach, before you call vim.lsp.completion.enable(… {autotrigger=true}). See the lsp-attach example.
- Call vim.lsp.completion.get() from an InsertCharPre autocommand.

If the server provides commitCharacters for a completion item, typing one of those characters while the item is selected accepts the completion and then inserts the character. To disable this:

```
vim.lsp.completion.enable(true, client_id, bufnr, { commit_characters = false })
```

vim.lsp.completion.enable()
enable({enable}, {client_id}, {bufnr}, {opts}) Enables or disables completions from the given language client in the given buffer. Effects of enabling completions are:
- Calling vim.lsp.completion.get() uses the enabled clients to retrieve completion candidates.
- Selecting a completion item shows a preview popup ("completionItem/resolve") if 'completeopt' has "popup".
- Accepting a completion item using <c-y> applies side effects like expanding snippets, text edits (e.g. insert import statements) and executing associated commands. This works for completions triggered via autotrigger, 'omnifunc' or vim.lsp.completion.get().

Examples: lsp-attach lsp-completion

Note:
- vim.lsp.omnifunc() (i_CTRL-X_CTRL-O) queries every client that advertises completion, including clients that were disabled by enable(false). To suppress completions for a client, clear its capability on LspAttach: client.server_capabilities.completionProvider = nil.
- Behavior of autotrigger=true is controlled by the LSP triggerCharacters field. You can override it on LspAttach, see lsp-autocompletion.

Parameters:

- {enable} (boolean) True to enable, false to disable
- {client_id} (integer) Client ID
- {bufnr} (integer) Buffer handle, or 0 for the current buffer
- {opts} (table?) A table with the following fields:
  - {autotrigger}? (boolean) (default: false) When true, completion triggers automatically based on the server's `triggerCharacters`.
  - {cmp}? (fun(a: table, b: table): boolean) Comparator for sorting merged completion items from all servers.
  - {commit_characters}? (boolean) (default: true) When false, commit characters are ignored.
  - {convert}? (fun(item: lsp.CompletionItem): table) Transforms an LSP CompletionItem to complete-items.

get({opts}) vim.lsp.completion.get()
Triggers LSP completion once in the current buffer, if LSP completion is enabled (see lsp-attach lsp-completion).

Use CTRL-Y to select an item from the completion menu. complete_CTRL-Y

To invoke manually with CTRL-space, use this mapping:

```
-- Use CTRL-space to trigger LSP completion.
-- Use CTRL-Y to select an item. |complete_CTRL-Y|
vim.keymap.set('i', '<c-space>', function()
  vim.lsp.completion.get()
end)
```

Parameters:
- {opts} (table?) A table with the following fields:
  - {client_id}? (integer|integer[]) Only request from these clients. Defaults to all clients with completion enabled.
  - {ctx}? (lsp.CompletionContext) Completion context. Defaults to a trigger kind of `invoked`.

Lua module: vim.lsp.diagnostic lsp-diagnostic

This module provides functionality for requesting LSP diagnostics for a document/workspace and populating them using vim.Diagnostics. `DiagnosticRelatedInformation` is supported: it is included in the window shown by vim.diagnostic.open_float(). When the cursor is on a line with related information, gf jumps to the problem location.

from({diagnostics}) vim.lsp.diagnostic.from()
Converts the input `vim.Diagnostics` to LSP diagnostics.

Parameters:
- {diagnostics} (vim.Diagnostic[])

Return:
(lsp.Diagnostic[])

vim.lsp.diagnostic.get_namespace()
get_namespace({client_id}, {is_pull}, {pull_id}) Get the diagnostic namespace associated with an LSP client vim.diagnostic for diagnostics

Parameters:
- {client_id} (integer) The id of the LSP client
- {is_pull} (boolean?) Whether the namespace is for a pull or push client. Defaults to `false` (push).
- {pull_id} (string?) (default: nil) Optional identifier for pull diagnostic providers. Only used if `is_pull` is `true`.

vim.lsp.diagnostic.on_diagnostic()
on_diagnostic({error}, {result}, {ctx}) lsp-handler for the method "textDocument/diagnostic"

See vim.diagnostic.config() for configuration options.

Parameters:
- {error} (lsp.ResponseError?)
- {result} (lsp.DocumentDiagnosticReport)
- {ctx} (lsp.HandlerContext)

vim.lsp.diagnostic.on_publish_diagnostics()
on_publish_diagnostics({_}, {params}, {ctx}) lsp-handler for the method "textDocument/publishDiagnostics"

See vim.diagnostic.config() for configuration options.

Parameters:
- {params} (lsp.PublishDiagnosticsParams)
- {ctx} (lsp.HandlerContext)

Lua module: vim.lsp.document_color lsp-document_color

This module provides LSP support for highlighting color references in a document. Highlighting is enabled by default.

color_presentation() vim.lsp.document_color.color_presentation()
Select from a list of presentations for the color under the cursor.

enable({enable}, {filter}, {opts}) vim.lsp.document_color.enable()
Enables or disables document color highlighting for the {filter}ed scope.

To "toggle", pass the inverse of `is_enabled()`:

```
vim.lsp.document_color.enable(not vim.lsp.document_color.is_enabled())
```

Parameters:
- {enable} (boolean?) True to enable, false to disable. (default: `true`)
- {filter} (table?) Optional filters kwargs,

- {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
- {client_id}? (integer, default: all) Client ID, or nil for all.

- {opts} (table?) A table with the following fields:
  - {style}? ('background'|'foreground'|'virtual'|string|fun(bufnr: integer, range: vim.Range, hex_code: string)) Highlight style. It can be one of the pre-defined styles, a string to be used as virtual text, or a function that receives the buffer handle, the range (start line, start col, end line, end col) and the resolved hex color. (default: 'background')

is_enabled({filter}) vim.lsp.document_color.is_enabled()
Query whether document colors are enabled in the {filter}ed scope.

Parameters:
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

Return:
(boolean)

Lua module: vim.lsp.inlay_hint lsp-inlay_hint

enable({enable}, {filter}) vim.lsp.inlay_hint.enable()
Enables or disables inlay hints for the {filter}ed scope.

To "toggle", pass the inverse of is_enabled():

```
vim.lsp.inlay_hint.enable(not vim.lsp.inlay_hint.is_enabled())
```

Attributes:
Since: 0.10.0

Parameters:
- {enable} (boolean?) true/nil to enable, false to disable
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

get({filter}) vim.lsp.inlay_hint.get()
Get the list of inlay hints, (optionally) restricted by buffer or range.

Example usage:

```
local hint = vim.lsp.inlay_hint.get({ bufnr = 0 })[1] -- 0 for current buffer

local client = vim.lsp.get_client_by_id(hint.client_id)
local resp = client:request_sync('inlayHint/resolve', hint.inlay_hint, 100, 0)
local resolved_hint = assert(
  resp and resp.result,
  resp and resp.err and vim.lsp.rpc.format_rpc_error(resp.err) or 'request failed'
)
vim.lsp.util.apply_text_edits(resolved_hint.textEdits, 0, client.encoding)

location = resolved_hint.label[1].location
client:request('textDocument/hover', {
  textDocument = { uri = location.uri },
  position = location.range.start,
})
```

Attributes:
Since: 0.10.0

Parameters:
- {filter} (table?) Optional filters kwargs:
  - {bufnr} (integer?)
  - {range} (lsp.Range?)

Return:
(table[]) A list of objects with the following fields:
- {bufnr} (integer)
- {client_id} (integer)
- {inlay_hint} (lsp.InlayHint)

is_enabled({filter}) vim.lsp.inlay_hint.is_enabled()
Query whether inlay hint is enabled in the {filter}ed scope

Attributes:
Since: 0.10.0

Parameters:
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

Return:
(boolean)

Lua module: vim.lsp.inline_completion

lsp-inline_completion

This module provides the LSP "inline completion" feature, for completing multiline text (e.g., whole methods) instead of just a word or line, which may result in "syntactically or semantically incorrect" code. Unlike regular completion, this is typically presented as overlay text instead of a menu of completion candidates.

LSP spec: https://microsoft.github.io/language-server-protocol/specifications/lsp/3.18/specification/#textDocument_inlineCompletion

To try it out, here is a quickstart example using Copilot: lsp-copilot

1. Install Copilot:

```
npm install --global @github/copilot-language-server
```

1. Define a config, (or copy `lsp/copilot.lua` from https://github.com/neovim/nvim-lspconfig):

```
 vim.lsp.config('copilot', {
  cmd = { 'copilot-language-server', '--stdio' },
  root_markers = { '.git' },
   init_options = {
     editorInfo = {
       name = 'Neovim', version = tostring(vim.version()) },
       editorPluginInfo = { name = 'Neovim', version = tostring(vim.version()) },
     },
})
```

1. Activate the config:

```
vim.lsp.enable('copilot')
```

1. Sign in to Copilot, or use the `:LspCopilotSignIn` command from https://github.com/neovim/nvim-lspconfig
2. Enable inline completion:

```
vim.lsp.inline_completion.enable()
```

1. Set a keymap for `vim.lsp.inline_completion.get()` and invoke the keymap.

vim.lsp.inline_completion.Item

Fields:

- `{client_id}` (`integer`) Client ID
- `{command}?` (`lsp.Command`) Corresponding server command.
- `{insert_text}` (`string|lsp.StringValue`) The text to be inserted, can be a snippet.
- `{range}?` (`vim.Range`) Which range it be applied.

enable({enable}, {filter}) vim.lsp.inline_completion.enable()

Enables or disables inline completion for the `{filter}`ed scope, inline completion will automatically be refreshed when you are in insert mode.

To "toggle", pass the inverse of `is_enabled()`:

```
vim.lsp.inline_completion.enable(not vim.lsp.inline_completion.is_enabled())
```

Parameters:

- `{enable}` (`boolean?`) true/nil to enable, false to disable
- `{filter}` (`table?`) Optional filters kwargs,
  - `{bufnr}?` (`integer`, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - `{client_id}?` (`integer`, default: all) Client ID, or nil for all.

get({opts}) vim.lsp.inline_completion.get()

Accept the currently displayed completion candidate to the buffer.

It returns false when no candidate can be accepted, so you can use the return value to implement a fallback:

```
 vim.keymap.set('i', '<Tab>', function()
  if not vim.lsp.inline_completion.get() then
    return '<Tab>'
  end
end, { expr = true, desc = 'Accept the current inline completion' })
```

Parameters:

- `{opts}` (`table?`) A table with the following fields:
  - `{bufnr}?` (`integer`, default: 0) Buffer handle, or 0 for current.
  - `{on_accept}?` (`fun(item: vim.lsp.inline_completion.Item): vim.lsp.inline_completion.Item?`) A callback triggered when a completion item is accepted. You can use it to modify the completion item that is about to be accepted and return it to apply the changes, or return `nil` to prevent the changes from being applied to the buffer so you can implement custom behavior.

Return:

(`boolean`) `true` if a completion was applied, else `false`.

is_enabled({filter}) vim.lsp.inline_completion.is_enabled()

Query whether inline completion is enabled in the `{filter}`ed scope

Parameters:

- `{filter}` (`table?`) Optional filters kwargs,
  - `{bufnr}?` (`integer`, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - `{client_id}?` (`integer`, default: all) Client ID, or nil for all.

select({opts}) vim.lsp.inline_completion.select()
Switch between available inline completion candidates.

Parameters:
- {opts} (table?) A table with the following fields:
  - {bufnr}? (integer) (default: current buffer)
  - {count}? (integer, default: v:count1) The number of candidates to move by. A positive integer moves forward by {count} candidates, while a negative integer moves backward by {count} candidates.
  - {wrap}? (boolean, default: true) Whether to loop around file or not. Similar to 'wrapscan'.

Lua module: vim.lsp.linked_editing_range lsp-linked_editing_range

The vim.lsp.linked_editing_range module enables "linked editing" via a language server's textDocument/linkedEditingRange request. Linked editing ranges are synchronized text regions, meaning changes in one range are mirrored in all the others. This is helpful in HTML files for example, where the language server can update the text of a closing tag if its opening tag was changed.

LSP spec: https://microsoft.github.io/language-server-protocol/specification/#textDocument_linkedEditingRange

enable({enable}, {filter}) vim.lsp.linked_editing_range.enable()
Enable or disable a linked editing session for the {filter}ed scope. The following is a practical usage example:

```
vim.lsp.start({
  name = 'html',
  cmd = '…',
  on_attach = function(client)
    vim.lsp.linked_editing_range.enable(true, { client_id = client.id })
  end,
})
```

Parameters:
- {enable} (boolean?) true or nil to enable, false to disable.
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

Lua module: vim.lsp.log lsp-log

The vim.lsp.log module provides logging for the Nvim LSP client.

When debugging language servers, it is helpful to enable extra-verbose logging of the LSP client RPC events. Example:

```
vim.lsp.log.set_level 'trace'
```

Then try to run the language server, and open the log with:

```
:log lsp
```

Note:
- Remember to DISABLE verbose logging ("debug" or "trace" level), else you may encounter performance issues.
- "ERROR" messages containing "stderr" only indicate that the log was sent to stderr. Many servers send harmless messages via stderr.

get_filename() vim.lsp.log.get_filename()
Returns the log filename.

Return:
(string) log filename

get_level() vim.lsp.log.get_level()
Gets the current log level.

Return:
(integer) current log level

set_format_func({handle}) vim.lsp.log.set_format_func()
Sets the formatting function used to format logs. If the formatting function returns nil, the entry won't be written to the log file.

Parameters:
- {handle} (fun(level:string, ...): string?) Function to apply to log entries. The default will log the level, date, source and line number of the caller, followed by the arguments.

set_level({level}) vim.lsp.log.set_level()
Sets the current log level.

Parameters:
- {level} (string|integer) One of vim.log.levels

Lua module: vim.lsp.on_type_formatting lsp-on_type_formatting

enable({enable}, {filter}) vim.lsp.on_type_formatting.enable()
Enables/disables on-type formatting globally or for the {filter}ed scope. The following are some practical usage examples:

```
-- Enable for all clients
vim.lsp.on_type_formatting.enable()

-- Enable for a specific client
vim.api.nvim_create_autocmd('LspAttach', {
  callback = function(ev)
    local client_id = ev.data.client_id
    local client = assert(vim.lsp.get_client_by_id(client_id))
    if client.name == 'rust-analyzer' then
      vim.lsp.on_type_formatting.enable(true, { client_id = client_id })
    end
  end,
})
```

Parameters:
- {enable} (boolean?) true/nil to enable, false to disable.
- {filter} (table?) Optional filters kwargs:
  - {client_id} (integer?) Client ID, or nil for all.

Lua module: vim.lsp.rpc

lsp-rpc

vim.lsp.rpc.Client Client RPC object

Fields:
- {is_closing} (fun(): boolean) Indicates if the RPC is closing.
- {notify} (fun(method: string, params: any): boolean) Sends a notification to the LSP server.
- {request} (fun(method: string, params: table?, callback: fun(err?: lsp.ResponseError, result: any, request_id: integer), notify_reply_callback?: fun(message_id: integer)):boolean,integer?) Sends a request to the LSP server.
- {terminate} (fun()) Terminates the RPC client.

connect({host_or_path}, {port}) vim.lsp.rpc.connect()
Create a LSP RPC client factory that connects to either:
- a named pipe (windows)
- a domain socket (unix)
- a host and port via TCP

Return a function that can be passed to the cmd field for vim.lsp.start().

Parameters:
- {host_or_path} (string) host to connect to or path to a pipe/domain socket
- {port} (integer?) TCP port to connect to. If absent the first argument must be a pipe

Return:
(fun(dispatchers: vim.lsp.rpc.Dispatchers): vim.lsp.rpc.Client)

format_rpc_error({err}) vim.lsp.rpc.format_rpc_error()
Constructs an error message from an LSP error object.

Parameters:
- {err} (table) The error object

Return:
(string) error_message The formatted error message

vim.lsp.rpc.rpc_response_error()
rpc_response_error({code}, {message}, {data}) Creates an RPC response table error to be sent to the LSP response.

Parameters:
- {code} (integer) RPC error code defined, see vim.lsp.protocol.ErrorCodes
- {message} (string?) arbitrary message to send to server
- {data} (any?) arbitrary data to send to server

Return:
(lsp.ResponseError)

See also:
- lsp.ErrorCodes See vim.lsp.protocol.ErrorCodes

start({cmd}, {dispatchers}, {extra_spawn_params}) vim.lsp.rpc.start() Starts an LSP server process and create an LSP RPC client object to interact with it. Communication with the spawned process happens via stdio. For communication via TCP, spawn a process manually and use vim.lsp.rpc.connect()

Parameters:
- {cmd} (string[]) Command to start the LSP server.
- {dispatchers} (table?) Dispatchers for LSP message types.
  - {notification} (fun(method: string, params: table))
  - {on_error} (fun(code: integer, err: any))
  - {on_exit} (fun(code: integer, signal: integer))
  - {server_request} (fun(method: string, params: table): any?, lsp.ResponseError?)
- {extra_spawn_params} (table?) Additional context for the LSP server process.
  - {cwd}? (string) Working directory for the LSP server process
  - {detached}? (boolean) Detach the LSP server process from the current process
  - {env}? (table<string,string>) Additional environment variables for LSP server process. See vim.system()

Return:
(vim.lsp.rpc.Client)

Lua module: vim.lsp.semantic_tokens

lsp-semantic_tokens

enable({enable}, {filter}) vim.lsp.semantic_tokens.enable()
Enables or disables semantic tokens for the {filter}ed scope.

To "toggle", pass the inverse of is_enabled():

```
vim.lsp.semantic_tokens.enable(not vim.lsp.semantic_tokens.is_enabled())
```

Parameters:
- {enable} (boolean?) true/nil to enable, false to disable
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

force_refresh({bufnr}) vim.lsp.semantic_tokens.force_refresh()
Force a refresh of all semantic tokens

Only has an effect if the buffer is currently active for semantic token highlighting (vim.lsp.semantic_tokens.enable() has been called for it)

Parameters:
- {bufnr} (integer?) filter by buffer. All buffers if nil, current buffer if 0

vim.lsp.semantic_tokens.get_at_pos()
get_at_pos({bufnr}, {row}, {col}) Return the semantic token(s) at the given position. If called without arguments, returns the token under the cursor.

Parameters:
- {bufnr} (integer?) Buffer number (0 for current buffer, default)
- {row} (integer?) Position row (default cursor position)
- {col} (integer?) Position column (default cursor position)

Return:
(table?) List of tokens at position. Each token has the following fields:
- line (integer) line number, 0-based
- start_col (integer) start column, 0-based
- end_line (integer) end line number, 0-based
- end_col (integer) end column, 0-based
- type (string) token type as string, e.g. "variable"
- modifiers (table) token modifiers as a set. E.g., { static = true, readonly = true }
- client_id (integer)

vim.lsp.semantic_tokens.highlight_token()
highlight_token({token}, {bufnr}, {client_id}, {hl_group}, {opts}) Highlight a semantic token.

Apply an extmark with a given highlight group for a semantic token. The mark will be deleted by the semantic token engine when appropriate; for example, when the LSP sends updated tokens. This function is intended for use inside LspTokenUpdate callbacks.

Parameters:
- {token} (table) Semantic token, provided as ev.data.token in LspTokenUpdate
- {bufnr} (integer) Buffer to highlight, or 0 for current buffer.
- {client_id} (integer) ID of the vim.lsp.Client
- {hl_group} (string) Highlight group name
- {opts} (table?) Optional parameters:
  - {priority}? (integer, default: vim.hl.priorities.semantic_tokens + 3) Priority for the applied extmark.

is_enabled({filter}) vim.lsp.semantic_tokens.is_enabled()
Query whether semantic tokens is enabled in the {filter}ed scope

Parameters:
- {filter} (table?) Optional filters kwargs,
  - {bufnr}? (integer, default: all) Buffer number, or 0 for current buffer, or nil for all.
  - {client_id}? (integer, default: all) Client ID, or nil for all.

Lua module: vim.lsp.util

lsp-util

vim.lsp.util.open_floating_preview.Opts

Fields:
- {anchor_bias}? ('auto'|'above'|'below', default: 'auto') Adjusts placement relative to cursor.
  - "auto": place window based on which side of the cursor has more lines
  - "above": place the window above the cursor unless there are not enough lines to display the full window height.
  - "below": place the window below the cursor unless there are not enough lines to display the full window height.
- {border}? ('|'none'|'single'|'double'|'rounded'|'solid'|'shadow'|'bold'|(string|[string,string])[]) override border
- {close_events}? (table) List of events that closes the floating window
- {focus}? (boolean, default: true) If true, and if {focusable} is also true, focus an existing floating window with the same {focus_id}
- {focus_id}? (string) If a popup with this id is opened, then focus it
- {focusable}? (boolean, default: true) Make float focusable.
- {height}? (integer) Height of floating window
- {max_height}? (integer) Maximal height of floating window
- {max_width}? (integer) Maximal width of floating window
- {offset_x}? (integer) offset to add to col
- {offset_y}? (integer) offset to add to row
- {relative}? ('mouse'|'cursor'|'editor') (default: 'cursor')

- {title}? (string|[string,string][])
- {title_pos}? ('left'|'center'|'right')
- {width}? (integer) Width of floating window
- {wrap}? (boolean, default: true) Wrap long lines
- {wrap_at}? (integer) Character to wrap at for computing height when wrap is enabled
- {zindex}? (integer) override zindex, defaults to 50

vim.lsp.util.apply_text_document_edit()

apply_text_document_edit({text_document_edit}, {index}, {position_encoding}, {change_annotations}) Applies a TextDocumentEdit, which is a list of changes to a single document.

Parameters:
- {text_document_edit} (lsp.TextDocumentEdit)
- {index} (integer?) Optional index of the edit, if from a list of edits (or nil, if not from a list)
- {position_encoding} ('utf-8'|'utf-16'|'utf-32')
- {change_annotations} (table<string, lsp.ChangeAnnotation>?)

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocumentEdit

vim.lsp.util.apply_text_edits()

apply_text_edits({text_edits}, {bufnr}, {position_encoding}, {change_annotations}, {opts}) Applies a list of text edits to a buffer.
Note: this mutates text_edits (sorts in-place and adds _index fields).

Parameters:
- {text_edits} ((lsp.TextEdit|lsp.AnnotatedTextEdit)[])
- {bufnr} (integer) Buffer id
- {position_encoding} ('utf-8'|'utf-16'|'utf-32')
- {change_annotations} (table<string, lsp.ChangeAnnotation>?)
- {opts} (table?) A table with the following fields:
  - {keep_cursor}? (boolean, default: false) Keep the cursor on the text it is on, instead of letting the edits move it.

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textEdit

vim.lsp.util.apply_workspace_edit()

apply_workspace_edit({workspace_edit}, {position_encoding}) Applies a WorkspaceEdit.

Parameters:
- {workspace_edit} (lsp.WorkspaceEdit)
- {position_encoding} ('utf-8'|'utf-16'|'utf-32') (required)

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#workspace_applyEdit

buf_clear_references({bufnr}) vim.lsp.util.buf_clear_references()
Removes document highlights from a buffer.

Parameters:
- {bufnr} (integer?) Buffer id

vim.lsp.util.buf_highlight_references()

buf_highlight_references({bufnr}, {references}, {position_encoding}) Shows a list of document highlights for a certain buffer.

Parameters:
- {bufnr} (integer) Buffer id
- {references} (lsp.DocumentHighlight[]) objects to highlight
- {position_encoding} ('utf-8'|'utf-16'|'utf-32')

See also:
- https://microsoft.github.io/language-server-protocol/specification/#textDocumentContentChangeEvent

vim.lsp.util.convert_input_to_markdown_lines()

convert_input_to_markdown_lines({input}, {contents}) Converts any of MarkedString | MarkedString[] | MarkupContent into a list of lines containing valid markdown. Useful to populate the hover window for textDocument/hover, for parsing the result of textDocument/signatureHelp, and potentially others.

Note that if the input is of type MarkupContent and its kind is plaintext, then the corresponding value is returned without further modifications.

Parameters:
- {input} (lsp.MarkedString|lsp.MarkedString[]|lsp.MarkupContent)
- {contents} (string[]?) List of strings to extend with converted lines. Defaults to {}.

Return:
(string[]) extended with lines of converted markdown.

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocument_hover

vim.lsp.util.convert_signature_help_to_markdown_lines()

convert_signature_help_to_markdown_lines({signature_help}, {ft}, {triggers}) Converts textDocument/signatureHelp response to markdown lines.

Parameters:
- {signature_help} (lsp.SignatureHelp) Response of textDocument/SignatureHelp
- {ft} (string?) filetype that will be use as the lang for the label markdown code block
- {triggers} (string[]?) list of trigger characters from the lsp server. used to better determine parameter offsets

Return (multiple):
(`string[]?`) lines of converted markdown. (Range4?) highlight range for the active parameter

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocument_signatureHelp

get_effective_tabstop({`bufnr`}) vim.lsp.util.get_effective_tabstop()
Returns indentation size.

Parameters:
- {`bufnr`} (`integer?`) Buffer handle, defaults to current

Return:
(`integer`) indentation size

See also:
- 'shiftwidth'

vim.lsp.util.locations_to_items()
locations_to_items({`locations`}, {`position_encoding`}) Returns the items with the byte position calculated correctly and in sorted order, for display in quickfix and location lists.

The `user_data` field of each resulting item will contain the original `Location` or `LocationLink` it was computed from.

The result can be passed to the {`list`} argument of setqflist() or setloclist().

Parameters:
- {`locations`} (`lsp.Location[]|lsp.LocationLink[]`)
- {`position_encoding`} (`'utf-8'|'utf-16'|'utf-32'`)

Return:
(`vim.quickfix.entry[]`) See setqflist() for the format

vim.lsp.util.make_floating_popup_options()
make_floating_popup_options({`width`}, {`height`}, {`opts`}) Creates a table with sensible default options for a floating window. The table can be passed to nvim_open_win().

Parameters:
- {`width`} (`integer`) window width (in character cells)
- {`height`} (`integer`) window height (in character cells)
- {`opts`} (`vim.lsp.util.open_floating_preview.Opts?`)

Return:
(`vim.api.keyset.win_config`)

vim.lsp.util.make_formatting_params()
make_formatting_params({`options`}) Creates a `DocumentFormattingParams` object for the current buffer and cursor position.

Parameters:
- {`options`} (`lsp.FormattingOptions?`) with valid `FormattingOptions` entries

Return:
(`lsp.DocumentFormattingParams`) object

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocument_formatting

vim.lsp.util.make_given_range_params()
make_given_range_params({`start_pos`}, {`end_pos`}, {`bufnr`}, {`position_encoding`}) Using the given range in the current buffer, creates an object that is similar to vim.lsp.util.make_range_params().

Parameters:
- {`start_pos`} (`[integer,integer]?`) {`row,col`} mark-indexed position. Defaults to the start of the last visual selection.
- {`end_pos`} (`[integer,integer]?`) {`row,col`} mark-indexed position. Defaults to the end of the last visual selection.
- {`bufnr`} (`integer?`) buffer handle or 0 for current, defaults to current
- {`position_encoding`} (`'utf-8'|'utf-16'|'utf-32'`)

Return:
(`{ textDocument: { uri: lsp.DocumentUri }, range: lsp.Range }`)

vim.lsp.util.make_position_params()
make_position_params({`win`}, {`position_encoding`}) Creates a `TextDocumentPositionParams` object for the current buffer and cursor position.

Parameters:
- {`win`} (`integer?`) window-ID or 0 for current, defaults to current
- {`position_encoding`} (`'utf-8'|'utf-16'|'utf-32'`)

Return:
(`lsp.TextDocumentPositionParams`)

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocumentPositionParams

vim.lsp.util.make_range_params()
make_range_params({`win`}, {`position_encoding`}) Using the current position in the current buffer, creates an object that can be used as a building block for several LSP requests, such as `textDocument/codeAction`, `textDocument/colorPresentation`, `textDocument/rangeFormatting`.

Parameters:
- {`win`} (`integer?`) window-ID or 0 for current, defaults to current
- {`position_encoding`} (`"utf-8"|"utf-16"|"utf-32"`)

Return:
(`{ textDocument: { uri: lsp.DocumentUri }, range: lsp.Range }`)

vim.lsp.util.make_text_document_params()

make_text_document_params({`bufnr`}) Creates a `TextDocumentIdentifier` object for the current buffer.

Parameters:
- {`bufnr`} (`integer?`) Buffer handle, defaults to current

Return:
(`lsp.TextDocumentIdentifier`)

See also:
- https://microsoft.github.io/language-server-protocol/specifications/specification-current/#textDocumentIdentifier

vim.lsp.util.make_workspace_params()

make_workspace_params({`added`}, {`removed`}) Create the workspace params

Parameters:
- {`added`} (`lsp.WorkspaceFolder[]`)
- {`removed`} (`lsp.WorkspaceFolder[]`)

Return:
(`lsp.DidChangeWorkspaceFoldersParams`)

vim.lsp.util.open_floating_preview()

open_floating_preview({`contents`}, {`syntax`}, {`opts`}) Shows contents in a floating window.

Parameters:
- {`contents`} (`table`) of lines to show in window
- {`syntax`} (`string`) of syntax to set for opened buffer
- {`opts`} (`vim.lsp.util.open_floating_preview.Opts?`) with optional fields (additional keys are filtered with vim.lsp.util.make_floating_popup_options() before they are passed on to nvim_open_win())

Return (multiple):
(`integer`) bufnr of newly created float window (`integer`) winid of newly created float window preview window

preview_location({`location`}, {`opts`}) vim.lsp.util.preview_location()
Previews a location in a floating window

behavior depends on type of location:
- for Location, range is shown (e.g., function definition)
- for LocationLink, targetRange is shown (e.g., body of function definition)

Parameters:
- {`location`} (`lsp.Location|lsp.LocationLink`)
- {`opts`} (`vim.lsp.util.open_floating_preview.Opts?`)

Return (multiple):
(`integer?`) buffer id of float window (`integer?`) window id of float window

rename({`old_fname`}, {`new_fname`}, {`opts`}) vim.lsp.util.rename()
Rename old_fname to new_fname

Existing buffers are renamed as well, while maintaining their bufnr.

It deletes existing buffers that conflict with the renamed file name only when
- `opts` requests overwriting; or
- the conflicting buffers are not loaded, so that deleting them does not result in data loss.

Parameters:
- {`old_fname`} (`string`)
- {`new_fname`} (`string`)
- {`opts`} (`table?`) Options:
  - {`ignoreIfExists`}? (`boolean`)
  - {`overwrite`}? (`boolean`)

vim.lsp.util.show_document()

show_document({`location`}, {`position_encoding`}, {`opts`}) Shows document and optionally jumps to the location.

Parameters:
- {`location`} (`lsp.Location|lsp.LocationLink`)
- {`position_encoding`} (`'utf-8'|'utf-16'|'utf-32'`)
- {`opts`} (`table?`) A table with the following fields:
  - {`focus`}? (`boolean`) Whether to focus/jump to location if possible. (defaults: true)
  - {`reuse_win`}? (`boolean`) Jump to existing window if buffer is already open.

Return:
(`boolean`) `true` if succeeded

vim.lsp.util.symbols_to_items()

symbols_to_items({`symbols`}, {`bufnr`}, {`position_encoding`}) Converts symbols to quickfix list items.

Parameters:
- {`symbols`} (`lsp.DocumentSymbol[]|lsp.SymbolInformation[]|lsp.WorkspaceSymbol[]`) list of symbols
- {`bufnr`} (`integer?`) buffer handle or 0 for current, defaults to current
- {`position_encoding`} (`'utf-8'|'utf-16'|'utf-32'`)

Return:
(`vim.quickfix.entry[]`) See setqflist() for the format

Lua module: vim.lsp.protocol

lsp-protocol

vim.lsp.protocol.make_client_capabilities()

make_client_capabilities() Gets a new ClientCapabilities object describing the LSP client capabilities.

Return:
(`lsp.ClientCapabilities`)

vim.lsp.protocol.resolve_capabilities()

resolve_capabilities({`server_capabilities`}) Creates a normalized object describing LSP server capabilities.

Parameters:
- {`server_capabilities`} (`table`) Table of capabilities supported by the server

Return:
(`lsp.ServerCapabilities?`) Normalized table of capabilities

Structured async API for Lua code that waits on event-loop work.

vim.async lets Lua code wait for timers, callbacks, and other tasks without blocking Nvim's event loop. Async work runs inside tasks, which can pause at checkpoints and manage child tasks created while they are running.

Start async work with vim.async.run(). Inside a task, use vim.async.await() to wait for callback-style APIs or other tasks without blocking the event loop. Use vim.async.pawait() when an awaited operation can fail and the current task should continue.

Examples in this help use local async = vim.async for brevity.

Example: run async work without blocking Nvim:

```
local async = vim.async

async.run(function()
  vim.notify('waiting...')
  async.sleep(1000)
  vim.notify('done')
end)
```

Example: await a callback-style API. Callback results are returned unchanged, so an error-first callback still returns err, value:

```
local async = vim.async

async.run(function()
  local err, stat = async.await(2, fs_stat, 'notes.txt')
  if err then
    error(err, 0)
  end
  print(('notes.txt is %d bytes'):format(stat.size))
end)
```

A task has two roles:

- it is a handle that can be awaited, waited for, or closed
- it is a scope for child tasks created while the task is running

vim.async.run() creates a task. A top-level task starts immediately. A task created while another task is running becomes a child of that task, and its function starts when the parent reaches its next checkpoint. A parent task finishes only after its attached children finish. If a child fails without being handled, the parent fails and closes the remaining children.

Use Task:detach() for background work that should keep running after the current task finishes. A detached task becomes top-level work; the original parent no longer waits for it or closes it.

Awaiting a task observes that task's result; it does not attach the task to the awaiter or change which task owns it. Ownership is decided when the task is created.

Scheduling is cooperative. When a task awaits a timer, I/O operation, callback, or another task, vim.async saves the Lua stack and returns control to the event loop. Other callbacks can run while the task is paused. Nothing interrupts synchronous Lua code in the middle of a stack frame.

Checkpoints are the places where a task can pause, start pending child tasks, observe cancellation, and receive unhandled child failures. Inside a task, these operations are checkpoints:

- vim.async.await(...)
- vim.async.pawait(...)
- vim.async.checkpoint()
- successful return from the task function, which is the final checkpoint for child management

Convenience APIs such as vim.async.sleep() and vim.async.timeout() can also checkpoint because they call checkpointing APIs internally.

Closing a task closes its attached children. Cancellation is cooperative: Task:close() marks a task as closing, and the task observes that state at a checkpoint. If a task is suspended on a closable operation such as a timer or child task, vim.async closes that operation before reporting the cancellation.

Use vim.async.await() inside a task to suspend until work completes. It accepts a task, a callback-taking function, or an argument position plus a callback-taking function. await(task) returns the task result or raises the task failure. vim.async.pawait() is the async counterpart to pcall() for recoverable awaited-operation failures; it returns ok, ... instead of failing the current task for that awaited operation. It does not suppress cancellation or a failure already pending on the current task.

From synchronous code, use Task:wait() or Task:pwait() to pump the event loop until the task completes. Use Task:on_complete() to observe completion without blocking.

Coordination helpers work with task handles. vim.async.iter() yields completed task handles in completion order, vim.async.timeout() awaits a task with a deadline, and vim.async.semaphore(permits) creates a vim.async.Semaphore that limits how many tasks can hold a permit for a section at once.

vim.async.Closable

Fields:

- {close} (fun(self, callback?: fun()))
- {is_closing}? (fun(self): boolean)

vim.async.Semaphore

A semaphore manages an internal permit counter. Semaphore:acquire() consumes one permit and Semaphore:release() returns one permit. If no permits are available, acquire() suspends the current task until another task releases one.

The preferred way to use a Semaphore is with the with() method, which automatically acquires and releases the semaphore around a function call. This is useful for limiting sections that start external work and then await it, such as file reads, requests, or subprocesses.

```
local async = vim.async

async.run(function()
  local limit = async.semaphore(4)
  local tasks = {}

  for _, path in ipairs(paths) do
    table.insert(tasks, async.run(function()
      return limit:with(function()
        return read_file(path)
      end)
    end))
  end

  local next_task = async.iter(tasks)
  while true do
    local task = next_task()
    if task == nil then
      break
    end
    async.await(task)
  end
end)
```

Fields:

- {acquire} (fun(self: vim.async.Semaphore)) See Semaphore:acquire().
- {release} (fun(self: vim.async.Semaphore)) See Semaphore:release().
- {with} (fun(self: vim.async.Semaphore, fn: async fun(): R...): R...) See Semaphore:with().

vim.async.Task

Extends: vim.async.Closable

A coroutine-backed async operation and concurrency scope.

Use vim.async.run() to create tasks. A task may be awaited by more than one waiter. When a task is created inside another task, it is attached to that parent and becomes part of the parent's concurrency scope.

Fields:

- {close} (fun(self: vim.async.Task, callback: fun()?)) See Task:close().
- {completed} (fun(self: vim.async.Task): boolean) See Task:completed().
- {detach} (fun(self: vim.async.Task): vim.async.Task<R>) See Task:detach().
- {name}? (string) Name of the task

- {on_complete} (fun(self: vim.async.Task, callback: fun(err?: any, ...: R...)): fun())

  See Task:on_complete().
- {pwait} (fun(self: vim.async.Task, timeout: integer?): boolean, R...)

  See Task:pwait().
- {raise_on_error} (fun(self: vim.async.Task): vim.async.Task<R>) See

  Task:raise_on_error().
- {status} (fun(self: vim.async.Task): "running"|"awaiting"|"normal"|"completed")

  See Task:status().
- {traceback} (fun(self: vim.async.Task, msg: string?, level: integer?): string)

  See Task:traceback().
- {wait} (fun(self: vim.async.Task, timeout: integer?): R...)

  See Task:wait().

await({...}) vim.async.await()

Suspend the current task until an awaitable completes.

Accepts a task, a callback-taking function, or an argument position plus a callback-taking function. Raises awaited errors and current task-control errors.

The callback forms return callback arguments unchanged:

```
local async = vim.async

async.run(function()
  local err, stat = async.await(2, vim.uv.fs_stat, 'notes.txt')
  if err then
    error(err, 0)
  end
  print(stat.size)
end)
```

If a callback API starts cancellable work, return a closable handle from the await callback. Task:close() will close that handle if cancellation arrives while the task is suspended there.

```
local async = vim.async

async.run(function()
  local lines = async.await(function(done)
    return start_read_lines('notes.txt', done)
  end)
  render(lines)
end)
```

Parameters:
- {...} (any) see overloads

Overloads:
- async fun(func: (fun(callback: fun(...: R...)): vim.async.Closable?)): R...
- async fun(argc: integer, func: (fun(...: T..., callback: fun(...: R...)): vim.async.Closable?), ...: T...): R...
- async fun(task: vim.async.Task<R>): R...

Return:
(R...)

checkpoint() vim.async.checkpoint()

Start pending child tasks and deliver pending cancellation or task failure from the current task.

This does not yield to the event loop.

Use this after cleanup code that catches an async failure or close signal, so persistent task state is delivered again before normal execution continues.

```
local ok, err = pcall(cleanup_sensitive_work)
cleanup_resources()
vim.async.checkpoint()
if not ok then
  error(err, 0)
end
```

is_closing() vim.async.is_closing()

Returns true if the current task has been closed.

Can be used in an async function to do cleanup when a task is closing.

```
while not vim.async.is_closing() do
  poll_once()
  vim.async.sleep(1000)
end
```

Return:
(boolean)

iter({tasks}) vim.async.iter()

Iterate completed tasks in completion order.

The iterator yields task handles, not task results. Use vim.async.await() or vim.async.pawait() to retrieve each result. The tasks are observed in the order they complete, regardless of the order in the input list.

```
local async = vim.async

async.run(function()
  local tasks = {
    async.run(function() return 'cache', read_cache() end):detach(),
    async.run(function() return 'disk', read_file() end):detach(),
  }

  for task in async.iter(tasks) do
    local ok, source, text = async.pawait(task)
    if ok then
      for _, other in ipairs(tasks) do
        if other ~= task then
          other:close()
        end
      end
      print(('loaded from %s'):format(source))
      return text
    end
  end
end)
```

If code must support PUC Lua 5.1, use the direct-call form instead of a generic for loop. The iterator may need to suspend while waiting for the next completed task, and PUC Lua 5.1 cannot yield from a generic-for iterator call.

```
local next_task = async.iter(tasks)
while true do
  local task = next_task()
  if task == nil then
    break
  end
  async.await(task)
end
```

Parameters:
- {tasks} (vim.async.Task<R>[]) A list of tasks to wait for and iterate over.

Return:
(async fun(): vim.async.Task<R>?) iterator that yields each completed task.

pawait({...}) vim.async.pawait()

Protected await.

Async counterpart to pcall(). Accepts the same forms as vim.async.await(), but returns a leading ok boolean for awaited-operation failures.

Use this when the awaited task or operation is allowed to fail and the current task should continue. Cancellation or already pending failure from the current task is not protected.

```
local async = vim.async

async.run(function()
  local ok, text_or_err = async.pawait(async.run(read_file, 'notes.txt'))
  if not ok then
    text_or_err = ''
  end

  show_buffer(text_or_err)
end)
```

Parameters:

- {...} (any) see overloads

Overloads:
- async fun(func: (fun(callback: fun(...: R...)): vim.async.Closable?)): boolean, R...

- async fun(argc: integer, func: (fun(...: T..., callback: fun(...: R...)): vim.async.Closable?), ...: T...): boolean, R...

- async fun(task: vim.async.Task<R>): boolean, R...

Return (multiple):
(boolean) ok
(R...) ... result or error
(_overload) true
(R...)
(_overload) false
(any)

run({func}, {...}) vim.async.run()

Create a task from an async function.

Top-level tasks start immediately. Child tasks are attached immediately and first run when their parent reaches a checkpoint.

Creating a task decides ownership. Awaiting the task later only observes its result; it does not attach the task to the awaiter.

```
local async = vim.async

async.run(function()
  local child = async.run(function()
    return read_file('notes.txt')
  end)

  local text = async.await(child)
  show_buffer(text)
end)
```

A task created from synchronous code is top-level:

```
local task = vim.async.run(function()
  vim.async.sleep(100)
  return 'done'
end)

print(task:wait())
```

Parameters:
- {func} (async fun(...: T...): R...)

- {...} (T...) Arguments to pass to the function

Overloads:
- fun(name: string, func: async fun(...: T...), ...: T...): vim.async.Task<R...>

Return:
(vim.async.Task<R...>)

semaphore({permits}) vim.async.semaphore()

Create an async semaphore that allows up to a given number of acquisitions.

Prefer Semaphore:with() for most uses so permits are released reliably. Use Semaphore:acquire() and Semaphore:release() directly only when the acquire and release points cannot be expressed as one function call.

Parameters:
- {permits} (integer?) (default: 1)

Return:
(vim.async.Semaphore)

Semaphore:acquire() Semaphore:acquire()

Acquire a semaphore permit.

If the internal counter is greater than zero, decrement it by 1 and return immediately. If it is 0, wait until Semaphore:release() is called.

Semaphore:release() Semaphore:release()

Release a semaphore permit.

Increments the internal counter by 1 and can wake a task waiting in Semaphore:acquire().

Calling this more times than permits were acquired raises an error.

Semaphore:with({fn}) Semaphore:with()

Executes a function while holding one semaphore permit.

This acquires the semaphore before running the function and releases it after the function completes, even if it errors or the current task is closed.

Parameters:
- {fn} (async fun(): R...) Function to execute within the semaphore's context.

Return:
(R...) Result(s) of the executed function.

sleep({duration}) vim.async.sleep()

Asynchronously sleep for a given duration.

Suspends the current task for the given duration without blocking the event loop. After the delay and timer cleanup complete, sleep() returns to its caller through the runtime's schedule hook.

```
vim.async.run(function()
  vim.async.sleep(100)
  vim.notify('resumed later')
end)
```

Parameters:
- {duration} (integer) ms

Task:close({callback}) Task:close()

Request cooperative close for the task and all of its children.

The optional callback observes task completion and may run immediately if the task has already completed.

Closing is cooperative. The task observes the close request at a checkpoint such as vim.async.await() or vim.async.checkpoint(). If the task is suspended on an owned closable operation, that operation is closed before the task reports "closed".

Parameters:
- {callback} (fun()?)

Task:completed() Task:completed()

Returns whether the Task has completed.

Return:
(boolean)

Task:detach() Task:detach()

Detach a task from its parent.

The task becomes a top-level task. If it was waiting for a parent checkpoint, it is scheduled to start.

Use this for background work that should not be cancelled when the current task finishes. Detached task failures no longer fail the original parent, so observe them explicitly with Task:on_complete(), Task:wait(), or vim.async.await().

```
vim.async.run(function()
  while true do
    refresh_index()
    vim.async.sleep(1000)
  end
end):detach()
```

Return:
(vim.async.Task<R>)

Task:on_complete({callback}) Task:on_complete()

Add a callback to be run when the Task has completed.

If the Task is already done when this method is called, the callback is called immediately with the results.

This only observes completion. It does not start a pending task.

Parameters:
- {callback} (fun(err?: any, ...: R...))

Return:
(fun()) unsubscribe

Task:pwait({timeout}) Task:pwait()

Protected-call version of Task:wait().

Equivalent to pcall(task.wait, task, timeout).

```
local ok, result_or_err = task:pwait(1000)
if not ok then
  vim.notify(tostring(result_or_err), vim.log.levels.ERROR)
end
```

Parameters:
- {timeout} (integer?)

Return (multiple):
(boolean)
(R...)

Task:raise_on_error() Task:raise_on_error()

Raise this task's error when it completes.

Use this for detached or top-level fire-and-forget tasks whose completion will not otherwise be observed. Attached task errors already propagate to their parent.

Detached tasks do not raise errors automatically. Detaching changes ownership only; their completion can still be handled with vim.async.await(), Task:wait(), Task:pwait(), or Task:on_complete().

Return:
(vim.async.Task<R>) self

Task:status() Task:status()

Returns the status of the task:
- "running": task is currently executing Lua code
- "normal": task is active but another coroutine is running
- "awaiting": task is suspended at a checkpoint or waiting for children
- "completed": task and all attached children have completed

Return:
("running"|"awaiting"|"normal"|"completed")

Task:traceback({msg}, {level}) Task:traceback()

Get the traceback of a task when it is not active. Will also get the traceback of nested tasks.

Parameters:
- {msg} (string?)
- {level} (integer?)

Return:
(string) traceback

Task:wait({timeout}) Task:wait()

Synchronously wait for the Task to complete.

If a timeout is provided, waits for the given time in milliseconds before failing with "timeout". With no timeout, waits indefinitely.

This is for synchronous code. Inside a task, prefer vim.async.await() so the current task suspends instead of pumping the event loop itself.

```
local result = task:wait(10) -- wait for 10ms or raise "timeout"

local result = task:wait() -- wait indefinitely
```

Parameters:
- {timeout} (integer?)

Return:
(R...)

timeout({duration}, {task}) vim.async.timeout()

Await a task with a timeout.

If the task completes first, returns or raises the task result as vim.async.await() would. If the deadline wins, closes the task and

raises "timeout" after the target task finishes cancellation cleanup.

```
local async = vim.async

async.run(function()
  local task = async.run(read_file, 'notes.txt')
  local text = async.timeout(5000, task)
  show_buffer(text)
end)
```

Parameters:

- {duration} (integer) Timeout duration in milliseconds
- {task} (vim.async.Task<R>)

Return:

(R...)

wrap({argc}, {func}) vim.async.wrap()

Create an async function from a callback-style function.

The callback is inserted at argument position argc. If func returns a closable handle, it is closed when the awaiting task is cancelled.

This is a reusable wrapper around vim.async.await(). Use it when the same callback API is awaited from more than one place.

```
local async = vim.async
local fs_stat = async.wrap(2, vim.uv.fs_stat)

async.run(function()
  local err, stat = fs_stat(vim.api.nvim_buf_get_name(0))
  if not err and stat then
    print(stat.size)
  end
end)
```

Parameters:

- {argc} (integer)
- {func} (fun(...: T..., callback: fun(...: R...)): vim.async.Closable?)

Return:

(async fun(...: T...): R...)

Lua BitOp

Adapted from https://bitop.luajit.org.

Lua BitOp is a C extension module for Lua 5.1/5.2 which adds bitwise operations on numbers.

API FUNCTIONS

lua-bit-api

This list of API functions is not intended to replace a tutorial. If you are not familiar with the terms used, you may want to study the Wikipedia article on bitwise operations (https://en.wikipedia.org/wiki/Bitwise_operation) first.

Loading the BitOp module

lua-bit-module

The suggested way to use the BitOp module is to add the following to the start of every Lua file that needs one of its functions:

```
local bit = require("bit")
```

This makes the dependency explicit, limits the scope to the current file and provides faster access to the bit.* functions, too. It's good programming practice not to rely on the global variable bit being set (assuming some other part of your application has already loaded the module). The require function ensures the module is only loaded once, in any case.

Defining Shortcuts

lua-bit-shortcuts

It's a common (but not a required) practice to cache often used module functions in locals. This serves as a shortcut to save some typing and also speeds up resolving them (only relevant if called hundreds of thousands of times).

```
local bnot = bit.bnot
local band, bor, bxor = bit.band, bit.bor, bit.bxor
local lshift, rshift, rol = bit.lshift, bit.rshift, bit.rol
-- etc...

-- Example use of the shortcuts:
local function tr_i(a, b, c, d, x, s)
  return rol(bxor(c, bor(b, bnot(d))) + a + x, s) + b
end
```

Remember that `and`, `or` and `not` are reserved keywords in Lua. They cannot be used for variable names or literal field names. That's why the corresponding bitwise functions have been named `band`, `bor`, and `bnot` (and `bxor` for consistency).

While we are at it: a common pitfall is to use bit as the name of a local temporary variable — well, don't! :-)

About the Examples

The examples below show small Lua one-liners. Their expected output is shown after `-->`. This is interpreted as a comment marker by Lua so you can cut & paste the whole line to a Lua prompt and experiment with it.

Note that all bit operations return signed 32 bit numbers (rationale). And these print as signed decimal numbers by default.

For clarity the examples assume the definition of a helper function `printx()`. This prints its argument as an unsigned 32 bit hexadecimal number on all platforms:

```
function printx(x)
  print("0x"..bit.tohex(x))
end
```

Bit operations

lua-bitop

bit.tobit({x}) bit.tobit()

Normalizes a number to the numeric range for bit operations and returns it. This function is usually not needed since all bit operations already normalize all of their input arguments. See lua-bit-semantics.

Example:

```
print(0xffffffff)               --> 4294967295 (see Note)
print(bit.tobit(0xffffffff))    --> -1
printx(bit.tobit(0xffffffff))   --> 0xffffffff
print(bit.tobit(0xffffffff + 1)) --> 0
print(bit.tobit(2^40 + 1234))   --> 1234
```

Note: lua-bit-hex-literals explains why the numbers printed in the first two lines differ (if your Lua installation uses a double number type).

bit.tohex({x} [, {n}]) bit.tohex()

Converts its first argument to a hex string. The number of hex digits is given by the absolute value of the optional second argument. Positive numbers between 1 and 8 generate lowercase hex digits. Negative numbers generate uppercase hex digits. Only the least-significant 4*|n| bits are used. The default is to generate 8 lowercase hex digits.

Example:

```
print(bit.tohex(1))              --> 00000001
print(bit.tohex(-1))             --> ffffffff
print(bit.tohex(0xffffffff))     --> ffffffff
print(bit.tohex(-1, -8))         --> FFFFFFFF
print(bit.tohex(0x21, 4))        --> 0021
print(bit.tohex(0x87654321, 4))  --> 4321
```

bit.bnot({x}) bit.bnot()

Returns the bitwise `not` of its argument.

Example:

```
print(bit.bnot(0))            --> -1
printx(bit.bnot(0))           --> 0xffffffff
print(bit.bnot(-1))           --> 0
print(bit.bnot(0xffffffff))   --> 0
printx(bit.bnot(0x12345678))  --> 0xedcba987
```

bit.bor({...}) bit.bor()
bit.band({...}) bit.band()
bit.bxor({...}) bit.bxor()

Returns either the bitwise `or`, bitwise and, or bitwise `xor` of all of its arguments. Note that more than two arguments are allowed.

Example:

```
print(bit.bor(1, 2, 4, 8))               --> 15
printx(bit.band(0x12345678, 0xff))       --> 0x00000078
printx(bit.bxor(0xa5a5f0f0, 0xaa55ff00))  --> 0x0ff00ff0
```

bit.lshift({x}, {n}) bit.lshift()
bit.rshift{(x}, {n}) bit.rshift()
bit.arshift{(x}, {n}) bit.arshift()

Returns either the bitwise `logical left-shift`, bitwise `logical right-shift`, or bitwise `arithmetic right-shift` of its first argument by the number of bits given by the second argument.

Logical shifts treat the first argument as an unsigned number and shift in 0-bits. Arithmetic right-shift treats the most-significant bit as a sign bit and replicates it. Only the lower 5 bits of the shift count are used (reduces to the range [0..31]).

Example:

```
print(bit.lshift(1, 0))             --> 1
print(bit.lshift(1, 8))             --> 256
print(bit.lshift(1, 40))            --> 256
print(bit.rshift(256, 8))           --> 1
print(bit.rshift(-256, 8))          --> 16777215
print(bit.arshift(256, 8))          --> 1
print(bit.arshift(-256, 8))         --> -1
printx(bit.lshift(0x87654321, 12))  --> 0x54321000
printx(bit.rshift(0x87654321, 12))  --> 0x00087654
printx(bit.arshift(0x87654321, 12))  --> 0xfff87654
```

bit.rol({x}, {n}) bit.rol()
bit.ror({x}, {n}) bit.ror()

Returns either the bitwise `left rotation`, or bitwise `right rotation` of its first argument by the number of bits given by the second argument. Bits shifted out on one side are shifted back in on the other side.

Only the lower 5 bits of the rotate count are used (reduces to the range [0..31]).

Example:

```
printx(bit.rol(0x12345678, 12))  --> 0x45678123
printx(bit.ror(0x12345678, 12))  --> 0x67812345
```

bit.bswap({x}) bit.bswap()

Swaps the bytes of its argument and returns it. This can be used to convert little-endian 32 bit numbers to big-endian 32 bit numbers or vice versa.

Example:

```
printx(bit.bswap(0x12345678)) --> 0x78563412
printx(bit.bswap(0x78563412)) --> 0x12345678
```

Example Program

This is an implementation of the (naïve) Sieve of Eratosthenes algorithm. It counts the number of primes up to some maximum number.

A Lua table is used to hold a bit-vector. Every array index has 32 bits of the vector. Bitwise operations are used to access and modify them. Note that the shift counts don't need to be masked since this is already done by the BitOp shift and rotate functions.

```
local bit = require("bit")
local band, bxor = bit.band, bit.bxor
local rshift, rol = bit.rshift, bit.rol

local m = tonumber(arg and arg[1]) or 100000
if m < 2 then m = 2 end
local count = 0
local p = {}

for i=0,(m+31)/32 do p[i] = -1 end

for i=2,m do
  if band(rshift(p[rshift(i, 5)], i), 1) ~= 0 then
    count = count + 1
    for j=i+i,m,i do
      local jx = rshift(j, 5)
      p[jx] = band(p[jx], rol(-2, j))
    end
  end
end

io.write(string.format("Found %d primes up to %d\n", count, m))
```

Lua BitOp is quite fast. This program runs in less than 90 milliseconds on a 3 GHz CPU with a standard Lua installation, but performs more than a million calls to bitwise functions. If you're looking for even more speed, check out lua-luajit.

Caveats

lua-bit-caveats

Signed Results

Returning signed numbers from bitwise operations may be surprising to programmers coming from other programming languages which have both signed and unsigned types. But as long as you treat the results of bitwise operations uniformly everywhere, this shouldn't cause any problems.

Preferably format results with `bit.tohex` if you want a reliable unsigned string representation. Avoid the `"%x"` or `"%u"` formats for `string.format`. They fail on some architectures for negative numbers and can return more than 8 hex digits on others.

You may also want to avoid the default number to string coercion, since this is a signed conversion. The coercion is used for string concatenation and all standard library functions which accept string arguments (such as `print()` or `io.write()`).

Conditionals

If you're transcribing some code from C/C++, watch out for bit operations in conditionals. In C/C++ any non-zero value is implicitly considered as `true`. E.g. this C code:

```
if (x & 3) ...
```

must not be turned into this Lua code:

```
if band(x, 3) then ... -- wrong!
```

In Lua all objects except `nil` and `false` are considered `true`. This includes all numbers. An explicit comparison against zero is required in this case:

```
if band(x, 3) ~= 0 then ... -- correct!
```

Comparing Against Hex Literals

Comparing the results of bitwise operations (signed numbers) against hex literals (unsigned numbers) needs some additional care. The following conditional expression may or may not work right, depending on the platform you run it on:

```
bit.bor(x, 1) == 0xffffffff
```

E.g. it's never true on a Lua installation with the default number type. Some simple solutions:

Never use hex literals larger than 0x7fffffff in comparisons:

```
bit.bor(x, 1) == -1
```

Or convert them with bit.tobit() before comparing:

```
bit.bor(x, 1) == bit.tobit(0xffffffff)
```

Or use a generic workaround with bit.bxor():

```
bit.bxor(bit.bor(x, 1), 0xffffffff) == 0
```

Or use a case-specific workaround:

```
bit.rshift(x, 1) == 0x7fffffff
```

OPERATIONAL SEMANTICS AND RATIONALE

lua-bit-semantics

Input and Output Ranges

lua-bit-io-ranges

Bitwise operations cannot sensibly be applied to FP numbers (or their underlying bit patterns). They must be converted to integers before operating on them and then back to FP numbers.

It's desirable to define semantics that work the same across all platforms. This dictates that all operations are based on the common denominator of 32 bit integers. The `float` type provides only 24 bits of precision. This makes it unsuitable for use in bitwise operations. Lua BitOp refuses to compile against a Lua installation with this number type.

Bit operations only deal with the underlying bit patterns and generally ignore signedness (except for arithmetic right-shift). They are commonly displayed and treated like unsigned numbers, though.

But the Lua number type must be signed and may be limited to 32 bits. Defining the result type as an unsigned number would not be cross-platform safe. All bit operations are thus defined to return results in the range of signed 32 bit numbers (converted to the Lua number type).

lua-bit-hex-literals

Hexadecimal literals are treated as unsigned numbers by the Lua parser before converting them to the Lua number type. This means they can be out of the range of signed 32 bit integers if the Lua number type has a greater range. E.g. 0xffffffff has a value of 4294967295 in the default installation, but may be -1 on embedded systems. It's highly desirable that hex literals are treated uniformly across systems when used in bitwise operations. All bit operations accept arguments in the signed or the unsigned 32 bit range (and more, see below). Numbers with the same underlying bit pattern are treated the same by all operations.

Modular Arithmetic

lua-bit-modular-arith

Arithmetic operations on n-bit integers are usually based on the rules of modular arithmetic modulo 2^n. Numbers wrap around when the mathematical result of operations is outside their defined range. This simplifies hardware implementations and some algorithms actually require this behavior (like many cryptographic functions).

E.g. for 32 bit integers the following holds: `0xffffffff + 1 = 0`

Arithmetic modulo 2^32 is trivially available if the Lua number type is a 32 bit integer. Otherwise normalization steps must be inserted. Modular arithmetic should work the same across all platforms as far as possible:

- For the default number type of double, arguments can be in the range of ±2^51 and still be safely normalized across all platforms by taking their least-significant 32 bits. The limit is derived from the way doubles are converted to integers.
- The function bit.tobit can be used to explicitly normalize numbers to implement modular addition or subtraction. E.g.

```
              bit.tobit(0xffffffff + 1)
returns 0 on all platforms.
```

- The limit on the argument range implies that modular multiplication is usually restricted to multiplying already normalized numbers with small constants. FP numbers are limited to 53 bits of precision, anyway. E.g. (2^30+1)^2 does not return an odd number when computed with doubles.

BTW: The `tr_i` function shown here lua-bit-shortcuts is one of the non-linear functions of the (flawed) MD5 cryptographic hash and relies on modular arithmetic for correct operation. The result is fed back to other bitwise operations (not shown) and does not need to be normalized until the last step.

Restricted and undefined behaviors

lua-bit-restrictions

The following rules are intended to give a precise and useful definition (for the programmer), yet give the implementation (interpreter and compiler) the maximum flexibility and the freedom to apply advanced optimizations. It's strongly advised not to rely on undefined or implementation-defined behavior.

- All kinds of floating-point numbers are acceptable to the bitwise operations. None of them cause an error, but some may invoke undefined behavior:
  - `-0` is treated the same as `+0` on input and is never returned as a result.
  - Passing `±Inf`, `NaN` or numbers outside the range of `±2^51` as input yields an undefined result.
  - Non-integral numbers may be rounded or truncated in an implementation-defined way. This means the result could differ between different BitOp versions, different Lua VMs, on different platforms or even between interpreted vs. compiled code (as in LuaJIT). Avoid passing fractional numbers to bitwise functions. Use `math.floor()` or `math.ceil()` to get defined behavior.
- Lua provides auto-coercion of string arguments to numbers by default. This behavior is deprecated for bitwise operations.

Guide to using Lua in Nvim

Introduction

This guide introduces the basics of everyday Lua usage for configuring and controlling Nvim. It assumes some familiarity with the (non-Lua) basics of Nvim (commands, options, mappings, autocommands), which are covered in the user-manual.

This is not a comprehensive encyclopedia of all available features. Think of it as a survival kit: the bare minimum needed to comfortably get started on using Lua in Nvim.

- See lua-plugin for guidance on developing Lua plugins.
- See luaref and lua-concepts for details on the Lua programming language.

About the API

lua-guide-api

The purpose of this guide is to introduce the different ways of interacting with Nvim through Lua (the "API"). This API consists of three different layers:

1. The "Vim API" inherited from Vim: Ex-commands and vimscript-functions as well as user-functions in Vimscript. These are accessed through vim.cmd() and vim.fn respectively, which are discussed under lua-guide-vimscript below.
2. The "Nvim API" written in C for use in remote plugins and GUIs; see api. These functions are accessed through vim.api.
3. The "Lua API" written in and specifically for Lua. These are any other functions accessible through `vim.*` not mentioned already; see lua-stdlib.

This distinction is important, as API functions inherit behavior from their original layer: For example, Nvim API functions always need all arguments to be specified even if Lua itself allows omitting arguments (which are then passed as `nil`); and Vim API functions can use 0-based indexing even if Lua arrays are 1-indexed by default.

Through this, any possible interaction can be done through Lua without writing a complete new API from scratch. For this reason, functions are usually not duplicated between layers unless there is a significant benefit in functionality or performance (e.g., you can map Lua functions directly through nvim_create_autocmd() but not through :autocmd). In case there are multiple ways of achieving the same thing, this guide will only cover what is most convenient to use from Lua.

Using Lua

lua-guide-using-Lua

To run Lua code from the Nvim command line, use the :lua command:

```
:lua print("Hello!")
```

Note: each :lua command has its own scope and variables declared with the local keyword are not accessible outside of the command. This won't work:

```
:lua local foo = 1
:lua print(foo)
" prints "nil" instead of "1"
```

You can also use `:lua=`, which is equivalent to `:lua vim.print(...)`, to conveniently check the value of a variable or a table:

```
:lua =package
```

To run a Lua script in an external file, you can use the :source command exactly like for a Vimscript file:

```
:source ~/programs/baz/myluafile.lua
```

Finally, you can include Lua code in a Vimscript file by putting it inside a :lua-heredoc block:

```
lua << EOF
  local tbl = {1, 2, 3}
  for k, v in ipairs(tbl) do
    print(v)
  end
EOF
```

lua-guide-interrupt

Lua cannot normally be interrupted by CTRL-C (Lua does not implicitly "yield" to Nvim). To allow the user to interrupt potentially slow loops, periodically call vim.wait(). Passing `interval=0` skips the dummy timer setup, minimizing per-call overhead in a tight loop:

```
while true do
  -- ...work...
  local _, code = vim.wait(0, nil, 0)
  if code == -2 then -- CTRL-C.
    break
  end
end
```

See also: https://github.com/neovim/neovim/issues/6800

Using Lua files on startup

lua-guide-config

Nvim supports using `init.vim` or `init.lua` as the configuration file, but not both at the same time. This should be placed in your config directory (run `:echo stdpath('config')` to see where it is). Note that you can also use Lua in `init.vim` and Vimscript in `init.lua`, which will be covered below.

If you'd like to run any other Lua script on startup automatically, then you can simply put it in `plugin/` in your 'runtimepath'.

Lua modules

lua-guide-modules

If you want to load Lua files on demand, you can place them in the `lua/` directory in your 'runtimepath' and load them with `require`. (This is the Lua equivalent of Vimscript's autoload mechanism.)

Let's assume you have the following directory structure:

```
~/.config/nvim
|-- after/
|-- ftplugin/
|-- lua/
|   |-- myluamodule.lua
|   |-- other_modules/
|       |-- anothermodule.lua
|       |-- init.lua
|-- plugin/
|-- syntax/
|-- init.vim
```

Then the following Lua code will load `myluamodule.lua`:

```
require("myluamodule")
```

Note the absence of a `.lua` extension.

Similarly, loading `other_modules/anothermodule.lua` is done via

```
require('other_modules/anothermodule')
-- or
require('other_modules.anothermodule')
```

Note how "submodules" are just subdirectories; the `.` is equivalent to the path separator `/` (even on Windows).

A folder containing an init.lua file can be required directly, without having to specify the name of the file:

```
require('other_modules') -- loads other_modules/init.lua
```

Requiring a nonexistent module or a module which contains syntax errors aborts the currently executing script. `pcall()` may be used to catch such errors. The following example tries to load the `module_with_error` and only calls one of its functions if this succeeds and prints an error message otherwise:

```
local ok, mymod = pcall(require, 'module_with_error')
if not ok then
  print("Module had an error")
else
  mymod.func()
end
```

In contrast to :source, require() not only searches through all `lua/` directories under 'runtimepath', it also caches the module on first use. Calling `require()` a second time will therefore _not_ execute the script again and instead return the cached file. To rerun the file, you need to remove it from the cache manually first:

```
package.loaded['myluamodule'] = nil
require('myluamodule')    -- read and execute the module again from disk
```

See also:
- lua-module-load: how `require()` finds modules
- pcall()

Using Vim commands and functions from Lua

lua-guide-vimscript

All Vim commands and functions are accessible from Lua.

Vim commands

lua-guide-vim-commands

To run an arbitrary Vim command from Lua, pass it as a string to vim.cmd():

```
vim.cmd("colorscheme habamax")
```

Note that special characters will need to be escaped with backslashes:

```
vim.cmd("%s/\\Vfoo/bar/g")
```

An alternative is to use a literal string (see lua-literal) delimited by double brackets `[[ ]]` as in

```
vim.cmd([[%s/\Vfoo/bar/g]])
```

Another benefit of using literal strings is that they can be multiple lines; this allows you to pass multiple commands to a single call of vim.cmd():

```
vim.cmd([[
  highlight Error guibg=red
  highlight link Warning Error
]])
```

This is the converse of :lua-heredoc and allows you to include Vimscript code in your `init.lua`.

If you want to build your Vim command programmatically, the following form can be useful (all these are equivalent to the corresponding line above):

```
vim.cmd.colorscheme("habamax")
vim.cmd.highlight({ "Error", "guibg=red" })
vim.cmd.highlight({ "link", "Warning", "Error" })
```

Vimscript functions

lua-guide-vim-functions

Use vim.fn to call Vimscript functions from Lua. Data types between Lua and Vimscript are automatically converted:

```
print(vim.fn.printf('Hello from %s', 'Lua'))

local reversed_list = vim.fn.reverse({ 'a', 'b', 'c' })
vim.print(reversed_list) -- { "c", "b", "a" }

local function print_stdout(chan_id, data, name)
  print(data[1])
end

vim.fn.jobstart('ls', { on_stdout = print_stdout })
```

This works for both vimscript-functions and user-functions.

Note that hashes (#) are not valid characters for identifiers in Lua, so, e.g., autoload functions have to be called with this syntax:

```
vim.fn['my#autoload#function']()
```

See also:
- vimscript-functions: descriptions of all Vimscript functions
- function-list: Vimscript functions grouped by topic
- :runtime: run all Lua scripts matching a pattern in 'runtimepath'

Variables

lua-guide-variables

Variables can be set and read using the following wrappers, which directly correspond to their variable-scope:

- vim.g: global variables (g:)
- vim.b: variables for the current buffer (b:)
- vim.w: variables for the current window (w:)
- vim.t: variables for the current tabpage (t:)
- vim.v: predefined Vim variables (v:)
- vim.env: environment variables defined in the editor session

Data types are converted automatically. For example:

```
vim.g.some_global_variable = {
  key1 = "value",
  key2 = 300
}

vim.print(vim.g.some_global_variable)
--> { key1 = "value", key2 = 300 }
```

You can target specific buffers (via number), windows (via window-ID), or tabpages by indexing the wrappers:

```
vim.b[2].myvar = 1               -- set myvar for buffer number 2
vim.w[1005].myothervar = true    -- set myothervar for window ID 1005
```

Some variable names may contain characters that cannot be used for identifiers in Lua. You can still manipulate these variables by using the syntax

```
vim.g['my#variable'] = 1
```

Note that you cannot directly change fields of array variables. This won't work:

```
vim.g.some_global_variable.key2 = 400
vim.print(vim.g.some_global_variable)
--> { key1 = "value", key2 = 300 }
```

Instead, you need to create an intermediate Lua table and change this:

```
local temp_table = vim.g.some_global_variable
temp_table.key2 = 400
vim.g.some_global_variable = temp_table
vim.print(vim.g.some_global_variable)
--> { key1 = "value", key2 = 400 }
```

To delete a variable, simply set it to `nil`:

```
vim.g.myvar = nil
```

See also:
- lua-vim-variables

Options lua-guide-options

There are two complementary ways of setting options via Lua.

vim.opt

The most convenient way for setting global and local options, e.g., in `init.lua`, is through `vim.opt` and friends:

- vim.opt: behaves like :set
- vim.opt_global: behaves like :setglobal
- vim.opt_local: behaves like :setlocal

For example, the Vimscript commands

```
set smarttab
set nosmarttab
```

are equivalent to

```
vim.opt.smarttab = true
vim.opt.smarttab = false
```

In particular, they allow an easy way to working with list-like, map-like, and set-like options through Lua tables: Instead of

```
set wildignore=*.o,*.a,__pycache__
set listchars=space:_,tab:>~
set formatoptions=njt
```

you can use

```
vim.opt.wildignore = { '*.o', '*.a', '__pycache__' }
vim.opt.listchars = { space = '_', tab = '>~' }
vim.opt.formatoptions = { n = true, j = true, t = true }
```

These wrappers also come with methods that work similarly to their :set+=, :set^= and :set-= counterparts in Vimscript:

```
vim.opt.shortmess:append({ I = true })
vim.opt.wildignore:prepend('*.o')
vim.opt.whichwrap:remove({ 'b', 's' })
```

The price to pay is that you cannot access the option values directly but must use vim.opt:get():

```
print(vim.opt.smarttab)
--> {...} (big table)
print(vim.opt.smarttab:get())
--> false
vim.print(vim.opt.listchars:get())
--> { space = '_', tab = '>~' }
```

vim.o

For this reason, there exists a more direct variable-like access using `vim.o` and friends, similarly to how you can get and set options via `:echo &number` and `:let &listchars='space:_,tab:>~'`:

- vim.o: behaves like :set
- vim.go: behaves like :setglobal
- vim.bo: for buffer-scoped options
- vim.wo: for window-scoped options (can be double indexed)

For example:

```
vim.o.smarttab = false -- :set nosmarttab
print(vim.o.smarttab)
--> false
vim.o.listchars = 'space:_,tab:>~' -- :set listchars='space:_,tab:>~'
print(vim.o.listchars)
--> 'space:_,tab:>~'
vim.o.isfname = vim.o.isfname .. ',@-@' -- :set isfname+=@-@
print(vim.o.isfname)
--> '@,48-57,/,.,-,_,+,,,#,$,%,~,=,@-@'
vim.bo.shiftwidth = 4 -- :setlocal shiftwidth=4
print(vim.bo.shiftwidth)
--> 4
```

Just like variables, you can specify a buffer number or window-ID for buffer and window options, respectively. If no number is given, the current buffer or window is used:

```
vim.bo[4].expandtab = true -- sets expandtab to true in buffer 4
vim.wo.number = true       -- sets number to true in current window
vim.wo[0].number = true    -- same as above
vim.wo[0][0].number = true -- sets number to true in current buffer
                           -- in current window only
print(vim.wo[0].number)    --> true
```

- lua-options

Mappings lua-guide-mappings

You can map either Vim commands or Lua functions to key sequences.

Creating mappings lua-guide-mappings-set

Mappings can be created using vim.keymap.set(). This function takes three mandatory arguments:
- {mode} is a string or a table of strings containing the mode prefix for which the mapping will take effect. The prefixes are the ones listed in :map-modes, or "!" for :map!, or empty string for :map.
- {lhs} is a string with the key sequences that should trigger the mapping.
- {rhs} is either a string with a Vim command or a Lua function that should be executed when the {lhs} is entered. An empty string is equivalent to <Nop>, which disables a key.

Examples:

```
-- Normal mode mapping for Vim command
vim.keymap.set('n', '<Leader>ex1', '<cmd>echo "Example 1"<cr>')
-- Normal and Command-line mode mapping for Vim command
vim.keymap.set({'n', 'c'}, '<Leader>ex2', '<cmd>echo "Example 2"<cr>')
-- Normal mode mapping for Lua function
vim.keymap.set('n', '<Leader>ex3', vim.treesitter.start)
-- Normal mode mapping for Lua function with arguments
vim.keymap.set('n', '<Leader>ex4', function() print('Example 4') end)
```

You can map functions from Lua modules via

```
vim.keymap.set('n', '<Leader>pl1', require('plugin').action)
```

Note that this loads the plugin at the time the mapping is defined. If you want to defer the loading to the time when the mapping is executed (as for autoload functions), wrap it in `function() end`:

```
vim.keymap.set('n', '<Leader>pl2', function() require('plugin').action() end)
```

The fourth, optional, argument is a table with keys that modify the behavior of the mapping such as those from :map-arguments. The following are the most useful options:
- `buf`: If given, only set the mapping for the buffer with the specified number; `0` or `true` means the current buffer.

  ```
  -- set mapping for the current buffer
  vim.keymap.set('n', '<Leader>pl1', require('plugin').action, { buf = 0 })
  -- set mapping for the buffer number 4
  vim.keymap.set('n', '<Leader>pl1', require('plugin').action, { buf = 4 })
  ```

- `silent`: If set to `true`, suppress output such as error messages.

  ```
  vim.keymap.set('n', '<Leader>pl1', require('plugin').action, { silent = true })
  ```

- `expr`: If set to `true`, do not execute the {rhs} but use the return value as input. Special keycodes are converted automatically. For example, the following mapping replaces <down> with <c-n> in the popupmenu only:

  ```
  vim.keymap.set('c', '<down>', function()
    if vim.fn.pumvisible() == 1 then return '<c-n>' end
    return '<down>'
  end, { expr = true })
  ```

- `desc`: A string that is shown when listing mappings with, e.g., :map. This is useful since Lua functions as {rhs} are otherwise only listed as `Lua: <number> <source file>:<line>`. Plugins should therefore always use this for mappings they create.

  ```
  vim.keymap.set('n', '<Leader>pl1', require('plugin').action,
    { desc = 'Execute action from plugin' })
  ```

- `remap`: By default, all mappings are nonrecursive (i.e., vim.keymap.set() behaves like :noremap). If the {rhs} is itself a mapping that should be executed, set `remap = true`:

  ```
  vim.keymap.set('n', '<Leader>ex1', '<cmd>echo "Example 1"<cr>')
  -- add a shorter mapping
  vim.keymap.set('n', 'e', '<Leader>ex1', { remap = true })
  ```

  Note: <Plug> mappings are always expanded even with the default `remap = false`:

  ```
  vim.keymap.set('n', '[%', '<Plug>(MatchitNormalMultiBackward)')
  ```

Removing mappings lua-guide-mappings-del

A specific mapping can be removed with vim.keymap.del():

```
vim.keymap.del('n', '<Leader>ex1')
vim.keymap.del({'n', 'c'}, '<Leader>ex2', { buf = 0 })
```

See also:

- `vim.api.`nvim_buf_get_keymap(): return all mappings for buffer

Autocommands lua-guide-autocommands

An autocommand is a Vim command or a Lua function that is automatically executed whenever one or more events are triggered, e.g., when a file is read or written, or when a window is created. These are accessible from Lua through the Nvim API.

Creating autocommands lua-guide-autocommand-create

Autocommands are created using `vim.api.`nvim_create_autocmd(), which takes two mandatory arguments:
- `{event}`: a string or table of strings containing the event(s) which should trigger the command or function.
- `{opts}`: a table with keys that control what should happen when the event(s) are triggered.

The most important options are:

- `pattern`: A string or table of strings containing the autocmd-pattern. **Note:** Environment variable like `$HOME` and ~ are not automatically expanded; you need to explicitly use `vim.fn.`expand() for this.
- `command`: A string containing a Vim command.
- `callback`: A Lua function.

You must specify one and only one of `command` and `callback`. If `pattern` is omitted, it defaults to `pattern = '*'`. Examples:

```
vim.api.nvim_create_autocmd({"BufEnter", "BufWinEnter"}, {
  pattern = {"*.c", "*.h"},
  command = "echo 'Entering a C or C++ file'",
})

-- Same autocommand written with a Lua function instead
vim.api.nvim_create_autocmd({"BufEnter", "BufWinEnter"}, {
  pattern = {"*.c", "*.h"},
  callback = function() print("Entering a C or C++ file") end,
})

-- User event triggered by MyPlugin
vim.api.nvim_create_autocmd("User", {
  pattern = "MyPlugin",
  callback = function() print("My Plugin Works!") end,
})
```

Nvim will always call a Lua function with a single table containing information about the triggered autocommand. The most useful keys are
- `match`: a string that matched the `pattern` (see <amatch>)
- `buf`: the number of the buffer the event was triggered in (see <abuf>)
- `file`: the file name of the buffer the event was triggered in (see <afile>)
- `data`: a table with other relevant data that is passed for some events

For example, this allows you to set buffer-local mappings for some filetypes:

```
vim.api.nvim_create_autocmd("FileType", {
  pattern = "lua",
  callback = function(ev)
    vim.keymap.set('n', 'K', vim.lsp.buf.hover, { buf = ev.buf })
  end
})
```

This means that if your callback itself takes an (even optional) argument, you must wrap it in `function() end` to avoid an error:

```
vim.api.nvim_create_autocmd('TextYankPost', {
  callback = function() vim.hl.hl_op() end
})
```

(Since unused arguments can be omitted in Lua function definitions, this is equivalent to `function(args) ... end`.)

Instead of using a pattern, you can create a buffer-local autocommand (see autocmd-buflocal) with `buffer`; in this case, `pattern` cannot be used:

```
-- set autocommand for current buffer
vim.api.nvim_create_autocmd("CursorHold", {
  buffer = 0,
  callback = function() print("hold") end,
})

-- set autocommand for buffer number 33
vim.api.nvim_create_autocmd("CursorHold", {
  buffer = 33,
  callback = function() print("hold") end,
})
```

Similarly to mappings, you can (and should) add a description using `desc`:

```
vim.api.nvim_create_autocmd('TextYankPost', {
  callback = function() vim.hl.hl_op() end,
  desc = "Briefly highlight yanked text"
})
```

Finally, you can group autocommands using the `group` key; this will be covered in detail in the next section.

Grouping autocommands

lua-guide-autocommands-group

Autocommand groups can be used to group related autocommands together; see autocmd-groups. This is useful for organizing autocommands and especially for preventing autocommands to be set multiple times.

Groups can be created with `vim.api.`nvim_create_augroup(). This function takes two mandatory arguments: a string with the name of a group and a table determining whether the group should be cleared (i.e., all grouped autocommands removed) if it already exists. The function returns a number that is the internal identifier of the group. Groups can be specified either by this identifier or by the name (but only if the group has been created first).

For example, a common Vimscript pattern for autocommands defined in files that may be reloaded is

```
augroup vimrc
  " Remove all vimrc autocommands
  autocmd!
  au BufNewFile,BufRead *.html set shiftwidth=4
  au BufNewFile,BufRead *.html set expandtab
augroup END
```

This is equivalent to the following Lua code:

```
local mygroup = vim.api.nvim_create_augroup('vimrc', { clear = true })
vim.api.nvim_create_autocmd({ 'BufNewFile', 'BufRead' }, {
  pattern = '*.html',
  group = mygroup,
  command = 'set shiftwidth=4',
})
vim.api.nvim_create_autocmd({ 'BufNewFile', 'BufRead' }, {
  pattern = '*.html',
  group = 'vimrc',  -- equivalent to group=mygroup
  command = 'set expandtab',
})
```

Autocommand groups are unique for a given name, so you can reuse them, e.g., in a different file:

```
local mygroup = vim.api.nvim_create_augroup('vimrc', { clear = false })
vim.api.nvim_create_autocmd({ 'BufNewFile', 'BufRead' }, {
  pattern = '*.c',
  group = mygroup,
  command = 'set noexpandtab',
})
```

Deleting autocommands

lua-guide-autocommands-delete

You can use `vim.api.`nvim_clear_autocmds() to remove autocommands. This function takes a single mandatory argument that is a table of keys describing the autocommands that are to be removed:

```
-- Delete all BufEnter and InsertLeave autocommands
vim.api.nvim_clear_autocmds({event = {"BufEnter", "InsertLeave"}})

-- Delete all autocommands that uses "*.py" pattern
vim.api.nvim_clear_autocmds({pattern = "*.py"})

-- Delete all autocommands in group "scala"
vim.api.nvim_clear_autocmds({group = "scala"})

-- Delete all ColorScheme autocommands in current buffer
vim.api.nvim_clear_autocmds({event = "ColorScheme", buffer = 0 })
```

Note: Autocommands in groups will only be removed if the `group` key is specified, even if another option matches it.

- nvim_get_autocmds(): return all matching autocommands
- nvim_exec_autocmds(): execute all matching autocommands

User commands

lua-guide-commands

user-commands are custom Vim commands that call a Vimscript or Lua function. Just like built-in commands, they can have arguments, act on ranges, or have custom completion of arguments. As these are most useful for plugins, we will cover only the basics of this advanced topic.

Creating user commands

lua-guide-commands-create

User commands can be created via nvim_create_user_command(). This function takes three mandatory arguments:
- a string that is the name of the command (which must start with an uppercase letter to distinguish it from builtin commands);
- a string containing Vim commands or a Lua function that is executed when the command is invoked;
- a table with command-attributes; in addition, it can contain the keys `desc` (a string describing the command); `force` (set to `false` to avoid replacing an already existing command with the same name), and `preview` (a Lua function that is used for :command-preview).

Example:

```
vim.api.nvim_create_user_command('Test', 'echo "It works!"')
vim.cmd.Test()
--> It works!
```

(Note that the third argument is mandatory even if no attributes are given.)

Lua functions are called with a single table argument containing arguments and modifiers. The most important are:

- `name`: a string with the command name
- `fargs`: a table containing the command arguments split by whitespace (see <f-args>)
- `bang`: `true` if the command was executed with a `!` modifier (see <bang>)
- `line1`: the starting line number of the command range (see <line1>)
- `line2`: the final line number of the command range (see <line2>)
- `range`: the number of items in the command range: 0, 1, or 2 (see <range>)
- `count`: any count supplied (see <count>)
- `smods`: a table containing the command modifiers (see <mods>)

For example:

```
vim.api.nvim_create_user_command('Upper',
  function(opts)
    print(string.upper(opts.fargs[1]))
  end,
  { nargs = 1 })

vim.cmd.Upper('foo')
--> FOO
```

The `complete` attribute can take a Lua function in addition to the attributes listed in :command-complete.

```
vim.api.nvim_create_user_command('Upper',
  function(opts)
    print(string.upper(opts.fargs[1]))
  end,
  { nargs = 1,
    complete = function(ArgLead, CmdLine, CursorPos)
      -- return completion candidates as a list-like table
      return { "foo", "bar", "baz" }
    end,
})
```

Buffer-local user commands are created with `vim.api.`nvim_buf_create_user_command(). Here the first argument is the buffer number (`0` being the current buffer); the remaining arguments are the same as for nvim_create_user_command():

```
vim.api.nvim_buf_create_user_command(0, 'Upper',
  function(opts)
    print(string.upper(opts.fargs[1]))
  end,
  { nargs = 1 })
```

Deleting user commands

lua-guide-commands-delete

User commands can be deleted with `vim.api.`nvim_del_user_command(). The only argument is the name of the command:

```
vim.api.nvim_del_user_command('Upper')
```

To delete buffer-local user commands use `vim.api.`nvim_buf_del_user_command(). Here the first argument is the buffer number (`0` being the current buffer), and second is command name:

```
vim.api.nvim_buf_del_user_command(4, 'Upper')
```

Guide to developing Lua plugins for Nvim

Introduction

This document provides guidance for developing Nvim Lua plugins.

- See lua-guide for guidance on using Lua to configure and operate Nvim.
- See luaref and lua-concepts for details on the Lua programming language.

Creating your first plugin lua-plugin-new

Any Vimscript or Lua code file that lives in the right directory, automatically is a "plugin". There's no manifest or "registration" step.

You can try it right now:

1. Visit your config directory:

```
:exe 'edit' stdpath('config')
```

2. Create a `plugin/foo.lua` file in there.
3. Add something to it, like:

```
vim.print('Hello World')
```

4. Start `nvim` and notice that it prints "Hello World" in the messages area. Check `:messages` if you don't see it.

Besides `plugin/foo.lua`, which is always run at startup, you can define Lua modules in the `lua/` directory. Those modules aren't loaded until your `plugin/foo.lua`, or the user, calls `require(…)`.

Type safety lua-plugin-type-safety

Lua, as a dynamically typed language, is great for configuration. It provides virtually immediate feedback. But for larger projects, this can be a double-edged sword, leaving your plugin susceptible to unexpected bugs at the wrong time.

You can leverage LuaCATS or "emmylua" annotations https://luals.github.io/wiki/annotations/ along with lua-language-server ("LuaLS") https://luals.github.io/ to catch potential bugs in your CI before your plugin's users do. The Nvim codebase uses these annotations extensively.

TOOLS

- lua-typecheck-action https://github.com/marketplace/actions/lua-typecheck-action
- lua-language-server https://luals.github.io

Keymaps lua-plugin-keymaps

Avoid creating excessive keymaps automatically. Doing so can conflict with user mappings.

NOTE: An example for uncontroversial keymaps are buffer-local mappings for specific file types or floating windows, or <Plug> mappings.

A common approach to allow keymap configuration is to define a declarative DSL https://en.wikipedia.org/wiki/Domain-specific_language via a `setup` function.

However, doing so means that

- You will have to implement and document it yourself.
- Users will likely face inconsistencies if another plugin has a slightly different DSL.
- init.lua scripts that call such a `setup` function may throw an error if the plugin is not installed or disabled.

As an alternative, you can provide <Plug> mappings to allow users to define their own keymaps with vim.keymap.set().

- This requires one line of code in user configs.
- Even if your plugin is not installed or disabled, creating the keymap won't throw an error.

Another option is to simply expose a Lua function or user-commands.

Some benefits of <Plug> mappings are that you can

- Enforce options like `expr = true`.
- Use vim.keymap's built-in mode handling to expose functionality only for specific map-modes.
- Handle different map-modes differently with a single mapping, without adding mode checks to the underlying implementation.
- Detect user-defined mappings through hasmapto() before creating defaults.

Some benefits of exposing a Lua function are:

- Extensibility, if the function takes an options table as an argument.
- A cleaner UX, if there are many options and enumerating all combinations of options would result in a lot of <Plug> mappings.

NOTE: If your function takes an options table, users may still benefit from <Plug> mappings for the most common combinations.

KEYMAP EXAMPLE

In your plugin:

```
vim.keymap.set('n', '<Plug>(SayHello)', function()
    print('Hello from normal mode')
end)

vim.keymap.set('v', '<Plug>(SayHello)', function()
    print('Hello from visual mode')
end)
```

In the user's config:

```
vim.keymap.set({'n', 'v'}, '<leader>h', '<Plug>(SayHello)')
```

Initialization lua-plugin-init

Strictly separated configuration and smart initialization allow your plugin to work out of the box. Common approaches are:

- A Lua function, e.g. `setup(opts)` or `configure(opts)`, which only overrides the default configuration and does not contain any initialization logic.
- A Vimscript compatible table (e.g. in the vim.g or vim.b namespace) that your plugin reads from and validates at initialization time. See also lua-vim-variables.

Typically, automatic initialization logic is done in a plugin or ftplugin script. See also 'runtimepath'.

On the other hand, a single `setup(opts)` that combines configuration and initialization may be useful in specific cases:

- Customizing complex initialization, where there is a significant risk of misconfiguration.
- Requiring users to opt in for plugin functionality that should not be initialized automatically.

Keep in mind that this approach requires users to call `setup` in order to use your plugin, even if the default configuration is enough for them. Consider carefully whether your plugin benefits from combined `setup()` pattern before adopting it. This article chronicles the history and tradeoffs of `setup()`: https://mrcjkb.dev/posts/2023-08-22-setup.html

NOTE: A well designed plugin has minimal impact on startup time. See also lua-plugin-lazy.

Lazy loading lua-plugin-lazy

Some users like to micro-manage "lazy loading" of plugins by explicitly configuring which commands and key mappings load the plugin.

Your plugin should not depend on every user micro-managing their configuration in such a way. Nvim has a mechanism for every plugin to do its own implicit lazy-loading, via autoload (Vimscript) and `lua/` (Lua).

Plugin authors can provide "lazy loading" by providing a `plugin/<name>.lua` file which defines their commands and keymappings. This file should be small, and should not eagerly `require()` the rest of your plugin. Commands and mappings should do the `require()`.

Guidance:

- Plugins should arrange their "lazy" behavior once, instead of expecting every user to micromanage it.
- Keep `plugin/<name>.lua` small, avoid eagerly calling `require()` on modules until a command or mapping is actually used.

Defer require() calls lua-plugin-defer-require

`plugin/<name>.lua` scripts (plugin) are eagerly run at startup; this is intentional, so that plugins can setup the (minimal) commands and keymappings that users will use to invoke the plugin. This also means these "plugin/" files should NOT eagerly `require` Lua modules.

For example, instead of:

```
local foo = require('foo')
vim.api.nvim_create_user_command('MyCommand', function()
    foo.do_something()
end, {
  -- ...
})
```

which calls `require('foo')` as soon as the module is loaded, you can lazy-load it by moving the `require` into the command's implementation:

```
vim.api.nvim_create_user_command('MyCommand', function()
    local foo = require('foo')
    foo.do_something()
end, {
  -- ...
})
```

Likewise, if a plugin uses a Lua module as an entrypoint, it should defer `require` calls too.

NOTE: For a Vimscript alternative to `require`, see autoload.

NOTE: If you are worried about eagerly creating user commands, autocommands or keymaps at startup: Plugin managers that provide abstractions for lazy-loading plugins on such events do the same amount of work. There is no performance benefit for users to define lazy-loading entrypoints in their configuration instead of plugins defining it in `plugin/<name>.lua`.

NOTE: You can use --startuptime to profile the impact a plugin has on startup time.

Filetype-specific functionality lua-plugin-filetype

Consider making use of 'filetype' for any functionality that is specific to a filetype, by putting the initialization logic in a `ftplugin/{filetype}.lua` script.

For buffers owned by your plugin (often used to show a custom UI or view), typically your plugin will set a custom 'filetype'. In that case, it's useful to set the 'filetype' "as late as possible", so that users can override buffer-local settings after your plugin has (re)initialized the buffer.

FILETYPE EXAMPLE

A plugin tailored to Rust development might have initialization in `ftplugin/rust.lua`:

```
if not vim.g.loaded_my_rust_plugin then
    -- Initialize
end
-- NOTE: Using `vim.g.loaded_` prevents the plugin from initializing twice
-- and allows users to prevent plugins from loading
-- (in both Lua and Vimscript).
vim.g.loaded_my_rust_plugin = true

local bufnr = vim.api.nvim_get_current_buf()
-- do something specific to this buffer,
-- e.g. add a |<Plug>| mapping or create a command
vim.keymap.set('n', '<Plug>(MyPluginBufferAction)', function()
    print('Hello')
end, { buf = bufnr })
```

Opening files lua-plugin-open-file

To robustly open a file, see open-file.

Configuration lua-plugin-config

To allow users to override buffer-local configuration for filetypes owned by your plugin, publish a FileType event, "as late as possible". lua-plugin-filetype

Once you have merged the default configuration with the user's config, you should validate configs.

Validations could include:

- Correct types, see vim.validate()
- Unknown fields in the user config (e.g. due to typos). This can be tricky to implement, and may be better suited for a health check, to reduce overhead.

UI lua-plugin-ui

Some plugins have their own "UI" which they present in a buffer that the plugin "owns". In that buffer typically you will want to provide custom actions.

Besides creating <Plug> mappings, you may want to consider providing actions by defining an in-process LSP server. Offering actions as code-actions vim.lsp.buf.code_action() means the user can see all available actions using the default gra mapping to view the code-actions menu. They can even define mappings to a specific action by invoking `vim.lsp.buf.code_action()` with the `filter` + `apply` parameters:

```
vim.lsp.buf.code_action({
    apply = true,
    filter = function(a)
        return a.title == 'Do something'
    end,
})
```

Example: See `runtime/lua/vim/pack/_lsp.lua` for how vim.pack defines an in-process LSP server to provide interactive features in its `nvim-pack://confirm` buffer.

Troubleshooting lua-plugin-troubleshooting

While developing a plugin, you can use the :restart command to see the result of code changes in your plugin.

HEALTH

Nvim's "health" framework gives plugins a simple way to report status checks to users. See health-dev for an example.

Basically, this just means your plugin will have a `lua/{plugin}/health.lua` file. :checkhealth will automatically find this file when it runs.

Some things to validate:

- User configuration
- Proper initialization
- Presence of Lua dependencies (e.g. other plugins)
- Presence of external dependencies

MINIMAL CONFIG TEMPLATE

It can be useful to provide a template for a minimal configuration, along with a guide on how to use it to reproduce issues.

Versioning and releases lua-plugin-versioning

Consider:

- Use vim.deprecate() or a `---@deprecate` annotation when you need to communicate a (future) breaking change or discouraged practice.
- Using SemVer https://semver.org/ tags and releases to properly communicate bug fixes, new features, and breaking changes.
- Automating versioning and releases in CI.
- Publishing to luarocks https://luarocks.org, especially if your plugin has dependencies or components that need to be built; or if it could be a dependency for another plugin.

Lua engine Lua

INTRODUCTION lua-intro

The Lua 5.1 script engine is builtin and always available. Try this command to get an idea of what lurks beneath:

```
:lua vim.print(package.loaded)
```

Nvim includes a "standard library" lua-stdlib for Lua. It complements the "editor stdlib" (vimscript-functions + Ex-commands) and the API, all of which can be used from Lua code (lua-vimscript vim.api). These three namespaces form the Nvim programming interface.

Lua plugins and user config are automatically discovered and loaded, just like Vimscript. See lua-guide for practical guidance.

You can also run Lua scripts from your shell using the -l argument:

```
nvim -l foo.lua [args...]
```

lua-compat

Lua 5.1 is the permanent interface for Nvim Lua. Plugins should target Lua 5.1 as specified in luaref; later versions (which are essentially different, incompatible, dialects) are not supported. This includes extensions such as `goto` that some Lua 5.1 interpreters like LuaJIT may support.

lua-luajit

While Nvim officially only requires Lua 5.1 support, it should be built with LuaJIT or a compatible fork on supported platforms for performance reasons. LuaJIT also comes with useful extensions such as `ffi`, lua-profile, and enhanced standard library functions; these cannot be assumed to be available, and Lua code in init.lua or plugins should check the `jit` global variable before using them:

```
if jit then
  -- code for luajit
else
  -- code for plain lua 5.1
end
```

One exception is the LuaJIT `bit` extension, which is always available: when built with PUC Lua, Nvim includes a fallback implementation which provides `require("bit")`. See lua-bit.

lua-profile

If Nvim is built with LuaJIT, Lua code can be profiled via

```
-- Start a profiling session:
require('jit.p').start('ri1', '/tmp/profile')

-- Perform arbitrary tasks (use plugins, scripts, etc.) ...

-- Stop the session. Profile is written to /tmp/profile.
require('jit.p').stop()
```

See https://luajit.org/ext_profiler.html or the `p.lua` source for details:

```
:lua vim.cmd.edit(package.searchpath('jit.p', package.path))
```

LUA CONCEPTS AND IDIOMS lua-concepts

Lua is very simple, and _consistent_: while there are some quirks, once you internalize those quirks, everything works the same everywhere. Scopes (closures) in particular are very consistent, unlike JavaScript or most other languages.

Lua has three fundamental mechanisms—one for "each major aspect of programming": tables, closures, and coroutines.
https://www.lua.org/doc/cacm2018.pdf

- Tables are the "object" or container datastructure: they represent both lists and maps, you can extend them to represent your own datatypes and change their behavior using metatables (like Python's "datamodel").
- EVERY scope in Lua is a closure: a function is a closure, a module is a closure, a do block (lua-do) is a closure--and they all work the same. A Lua module is literally just a big closure discovered on the "path" (where your modules are found: package.cpath).
- Stackful coroutines enable cooperative multithreading, generators, and versatile control for both Lua and its host (Nvim).

lua-error-handling

Lua functions may throw lua-errors for exceptional (unexpected) failures, which you can handle with pcall(). lua-result-or-message
When failure is normal and expected, it's idiomatic to return `nil` which signals to the caller that failure is not "exceptional" and must be handled. This "result-or-message" pattern is expressed as the multi-value return type `any|nil,nil|string`, or in LuaLS notation:

```
---@return any|nil    # result on success, nil on failure.
---@return nil|string # nil on success, error message on failure.
```

Examples of the "result-or-message" pattern:

- vim.ui.open()
- io.open()
- luv-error-handling

When a caller can't proceed on failure, it's idiomatic to `assert()` the "result-or-message" result:

```
local value = assert(fn())
```

Guidance: use the "result-or-message" pattern for...

- Functions where failure is expected, especially when communicating with the external world. E.g. HTTP requests or LSP requests often fail because of server problems, even if the caller did everything right.
- Functions that return a value, e.g. Foo:new().
- When there is a list of known error codes which can be returned as a third value (like luv-error-handling).

iterator

An iterator is just a function that can be called repeatedly to get the "next" value of a collection (or any other iterable). This interface is expected by for-in loops, produced by pairs(), supported by vim.iter, etc. https://www.lua.org/pil/7.1.html

iterable

An "iterable" is anything that vim.iter() can consume: tables, dicts, lists, iterator functions, tables implementing the __call() metamethod, and vim.iter() objects.

list-iterator

Iterators on lua-list tables have a "middle" and "end", whereas iterators in general may be logically infinite. Therefore some vim.iter operations (e.g. IterArray:rev()) make sense only on list-like tables (which are finite by definition).

lua-function-call

Lua functions can be called in multiple ways. Consider the function:

```
local foo = function(a, b)
    print("A: ", a)
    print("B: ", b)
end
```

The first way to call this function is:

```
foo(1, 2)
-- ==== Result ====
-- A: 1
-- B: 2
```

This way of calling a function is familiar from most scripting languages. In Lua, any missing arguments are passed as `nil`, and extra parameters are silently discarded. Example:

```
foo(1)
-- ==== Result ====
-- A: 1
-- B: nil
```

kwargs

When calling a function, you can omit the parentheses if the function takes exactly one string literal (`"foo"`) or table literal (`{1,2,3}`). The latter is often used to mimic "named parameters" ("kwargs" or "keyword args") as in languages like Python and C#. Example:

```
local func_with_opts = function(opts)
    local will_do_foo = opts.foo
    local filename = opts.filename
    -- ...
end

func_with_opts { foo = true, filename = "hello.world" }
```

There's nothing special going on here except that parentheses are implicitly added. But visually, this small bit of sugar gets reasonably close to a "keyword args" interface.

lua-regex

Lua intentionally does not support regular expressions, instead it has limited lua-patterns which avoid the performance pitfalls of extended regex. Lua scripts can also use Vim regex via vim.regex().

Examples:

```
print(string.match("foo123bar123", "%d+"))
-- 123
print(string.match("foo123bar123", "[^%d]+"))
-- foo
print(string.match("foo123bar123", "[abc]+"))
-- ba
print(string.match("foo.bar", "%.bar"))
-- .bar
```

lua-truthy

Only `false` and `nil` evaluate to "false" in Lua. All other values are "true".

IMPORTING LUA MODULES

lua-module-load

Modules are searched for under the directories specified in 'runtimepath' and packages-runtimepath, in the order they appear in the output of this command

```
:echo nvim_list_runtime_paths()
```

Any "." in the module name is treated as a directory separator when searching. For a module `foo.bar`, each directory is searched for `lua/foo/bar.lua`, then `lua/foo/bar/init.lua`. If no files are found, the directories are searched again for a shared library with a name matching `lua/foo/bar.?`, where `?` is a list of suffixes (such as `so` or `dll`) derived from the initial value of package.cpath. If still no files are found, Nvim falls back to Lua's default search mechanism. The first script found is run and `require()` returns the value returned by the script if any, else `true`.

The return value is cached after the first call to `require()` for each module, with subsequent calls returning the cached value without searching for, or executing any script. For further details see require().

For example, if 'runtimepath' is `foo,bar` and package.cpath was `./?.so;./?.dll` at startup, `require('mod')` searches these paths in order and loads the first module found ("first wins"):

```
foo/lua/mod.lua
foo/lua/mod/init.lua
bar/lua/mod.lua
bar/lua/mod/init.lua
foo/lua/mod.so
foo/lua/mod.dll
bar/lua/mod.so
bar/lua/mod.dll
```

Note:

- Although 'runtimepath' is tracked, Nvim does not track current values of package.path or package.cpath. If you happen to delete some paths from there you can set 'runtimepath' to trigger an update:

  ```
  let &runtimepath = &runtimepath
  ```

- Skipping paths from 'runtimepath' which contain semicolons applies both to package.path and package.cpath. Given that there are some badly written plugins using shell, which will not work with paths containing semicolons, it is better to not have them in 'runtimepath' at all.

lua-script-location

To get its own location, Lua scripts/modules can use debug.getinfo():

```
debug.getinfo(1, 'S').source:gsub('^@', '')
```

COMMANDS

lua-commands

These commands execute a Lua chunk from either the command line (:lua, :luado) or a file (:luafile) on the given line [range]. As always in Lua, each chunk has its own scope (closure), so only global variables are shared between command calls. The lua-stdlib modules, user modules, and anything else on package.path are available.

The Lua print() function redirects its output to the Nvim message area, with arguments separated by " " (space) instead of "\t" (tab).

:lua= :lua :lua {chunk} Executes Lua chunk {chunk}. If {chunk} starts with "=" the rest of the chunk is evaluated as an expression and printed. `:lua =expr` and `:=expr` are equivalent to `:lua print(vim.inspect(expr))`. E5107 E5108

Examples:

```
:lua vim.api.nvim_command('echo "Hello, Nvim!"')
```

To see the Lua version:

```
:lua print(_VERSION)
```

To see the LuaJIT version:

```
:lua =jit.version
```

:{range}lua Executes buffer lines in {range} as Lua code. Unlike :source, this always treats the lines as Lua code.

Example: select the following code and type ":lua<Enter>" to execute it:

```
print(string.format(
    'unix time: %s', os.time()))
```

:lua-heredoc

:lua << [trim] [{endmarker}] {script} {endmarker} Executes Lua script {script} from within Vimscript. You can omit [endmarker] after the "<<" and use a dot "." after {script} (similar to :append, :insert). Refer to :let-heredoc for more information.

Example:

```
function! CurrentLineInfo()
lua << EOF
local linenr = vim.api.nvim_win_get_cursor(0)[1]
local curline = vim.api.nvim_buf_get_lines(0, linenr - 1, linenr, false)[1]
print(string.format('Line [%d] has %d bytes', linenr, #curline))
EOF
endfunction
```

Note that the `local` variables will disappear when the block finishes. But not globals.

:luado

:[range]luado {body} Executes Lua chunk "function(line, linenr) {body} end" for each buffer line in [range], where `line` is the current line text (without <EOL>), and `linenr` is the current line number. If the function returns a string that becomes the text of the corresponding buffer line. Default [range] is the whole file: "1,$". E5109 E5110 E5111

Examples:

```
:luado return string.format("%s\t%d", line:reverse(), #line)

:lua require"lpeg"
:lua -- balanced parenthesis grammar:
:lua bp = lpeg.P{ "(" * ((1 - lpeg.S"()") + lpeg.V(1))^0 * ")" }
:luado if bp:match(line) then return "=>\t" .. line end
```

:luafile

:luafile {file} Execute Lua script in {file}. The whole argument is used as the filename (like :edit), spaces do not need to be escaped. Alternatively you can :source Lua files. E5111 E5112 E5113

Examples:

```
:luafile script.lua
:luafile %
```

luaeval()

lua-eval

The (dual) equivalent of "vim.eval" for passing Lua values to Nvim is "luaeval". "luaeval" takes an expression string and an optional argument used for _A inside expression and returns the result of the expression. It is semantically equivalent in Lua to:

```
local chunkheader = "local _A = select(1, ...) return "
function luaeval (expstr, arg)
    local chunk = assert(loadstring(chunkheader .. expstr, "luaeval"))
    return chunk(arg) -- return typval
end
```

Lua nils, numbers, strings, tables and booleans are converted to their respective Vimscript types. If a Lua string contains a NUL byte, it will be converted to a Blob. Conversion of other Lua types is an error.

The magic global "_A" contains the second argument to luaeval().

Example:

```
:echo luaeval('_A[1] + _A[2]', [40, 2])
" 42
:echo luaeval('string.match(_A, "[a-z]+")', 'XYXfoo123')
" foo
```

lua-table-ambiguous

Lua tables are used as both dictionaries and lists, so it is impossible to decide whether empty table is a list or a dict. Also Lua does not have integer numbers. To disambiguate these cases, we define: lua-list

1. Empty table is a list. Use vim.empty_dict() to represent empty dict.
2. Table with N consecutive (no nil values, aka "holes") integer keys 1…N is a list. See also list-iterator. lua-dict
3. Table with string keys, none of which contains NUL byte, is a dict.
4. Table with string keys, at least one of which contains NUL byte, is also considered to be a dictionary, but this time it is converted to a msgpack-special-map. lua-special-tbl E5100 E5101 E5102
5. Table with vim.type_idx key may be a dictionary, a list or floating-point value:
   - {[vim.type_idx]=vim.types.float, [vim.val_idx]=1} is converted to a floating-point 1.0. Note that by default integral Lua numbers are converted to Numbers, non-integral are converted to Floats. This variant allows integral Floats.
   - {[vim.type_idx]=vim.types.dictionary} is converted to an empty dictionary, {[vim.type_idx]=vim.types.dictionary, [42]=1, a=2} is converted to a dictionary {'a': 42}: non-string keys are ignored. Without vim.type_idx key tables with keys not fitting in 1., 2. or 3. are errors.
   - {[vim.type_idx]=vim.types.array} is converted to an empty list. As well as {[vim.type_idx]=vim.types.array, [42]=1}: integral keys that do not form a 1-step sequence from 1 to N are ignored, as well as all non-integral keys.

Examples:

```
:echo luaeval('math.pi')
:function Rand(x,y) " random uniform between x and y
:  return luaeval('(_A.y-_A.x)*math.random()+_A.x', {'x':a:x,'y':a:y})
:  endfunction
:echo Rand(1,10)
```

Note: Second argument to luaeval is converted ("marshalled") from Vimscript to Lua, so changes to Lua containers do not affect values in Vimscript. Return value is also always converted. When converting, msgpack-special-dicts are treated specially.

Vimscript v:lua interface

v:lua-call

From Vimscript the special v:lua prefix can be used to call Lua functions which are global or accessible from global tables. The expression

```
call v:lua.func(arg1, arg2)
```

is equivalent to the Lua chunk

```
return func(...)
```

where the args are converted to Lua values. The expression

```
call v:lua.somemod.func(args)
```

is equivalent to the Lua chunk

```
return somemod.func(...)
```

Lua module functions can be accessed like:

```
call v:lua.require'mypack'.func(arg1, arg2)
call v:lua.require'mypack.submod'.func(arg1, arg2)
```

Note: Only single quote form without parens is allowed. Using `require"mypack"` or `require('mypack')` as a prefix does NOT work.

You can use `v:lua` in "func" options like 'tagfunc', 'omnifunc', etc. For example consider the following Lua omnifunc handler:

```
function mymod.omnifunc(findstart, base)
  if findstart == 1 then
    return 0
  else
    return {'stuff', 'steam', 'strange things'}
  end
end
-- Note: The module ("mymod") must be a Lua global, or use require() as
-- shown above to access it from a package.
vim.bo[buf].omnifunc = 'v:lua.mymod.omnifunc'
```

You can also use `v:lua` to call Lua functions as Vimscript methods:

```
:eval arg1->v:lua.somemod.func(arg2)
```

Note: `v:lua` without a call is not allowed in a Vimscript expression: Funcrefs cannot represent Lua functions. The following are errors:

```
let g:Myvar = v:lua.myfunc        " Error
call SomeFunc(v:lua.mycallback)   " Error
let g:foo = v:lua                 " Error
let g:foo = v:['lua']             " Error
```

Lua standard modules

lua-stdlib

The Nvim Lua "standard library" (stdlib) is the `vim` module, which exposes various functions and sub-modules. It is always loaded, thus `require("vim")` is unnecessary.

You can peek at the module properties:

```
:lua vim.print(vim)
```

Result is something like this:

```
{
  _os_proc_children = <function 1>,
  _os_proc_info = <function 2>,
  ...
  api = {
    nvim__id = <function 5>,
    nvim__id_array = <function 6>,
    ...
  },
  deepcopy = <function 106>,
  gsplit = <function 107>,
  ...
}
```

To find documentation on e.g. the "deepcopy" function:

```
:help vim.deepcopy()
```

Note that underscore-prefixed functions (e.g. "_os_proc_children") are internal/private and must not be used by plugins.

VIM.UV

lua-loop **vim.uv**

`vim.uv` exposes the "luv" Lua bindings for the libUV library that Nvim uses for networking, filesystem, and process management, see luvref.txt. In particular, it allows interacting with the main Nvim luv-event-loop.

E5560 lua-loop-callbacks It is an error to directly invoke `vim.api` functions (except api-fast) in `vim.uv` callbacks. For example, this is an error:

```
local timer = vim.uv.new_timer()
timer:start(1000, 0, function()
  vim.api.nvim_command('echomsg "test"')
end)
```

To avoid the error, schedule the callback:

```
local timer = vim.uv.new_timer()
timer:start(1000, 0, vim.schedule_wrap(function()
  vim.api.nvim_command('echomsg "test"')
end))
```

(For one-shot timers, see vim.defer_fn(), which automatically adds the wrapping.)

Example: repeating timer

1. Save this code to a file.
2. Execute it with ":luafile %".

```
-- Create a timer handle (implementation detail: uv_timer_t).
local timer = vim.uv.new_timer()
local i = 0
-- Waits 1000ms, then repeats every 750ms until timer:close().
timer:start(1000, 750, function()
  print('timer invoked! i='..tostring(i))
  if i > 4 then
    timer:close()  -- Always close handles to avoid leaks.
  end
  i = i + 1
end)
print('sleeping');
```

Example: File-change detection watch-file

1. Save this code to a file.
2. Execute it with ":luafile %".
3. Use ":Watch %" to watch any file.
4. Try editing the file from another text editor.
5. Observe that the file reloads in Nvim (because on_change() calls :checktime).

```
local w = vim.uv.new_fs_event()
local function on_change(err, fname, status)
  -- Do work...
  vim.api.nvim_command('checktime')
  -- Debounce: stop/start.
  w:stop()
  watch_file(fname)
end
function watch_file(fname)
  local fullpath = vim.api.nvim_call_function(
    'fnamemodify', {fname, ':p'})
  w:start(fullpath, {}, vim.schedule_wrap(function(...)
    on_change(...) end))
end
vim.api.nvim_command(
  "command! -nargs=1 Watch call luaeval('watch_file(_A)', expand('<args>'))")
```

inotify-limitations

When on Linux you may need to increase the maximum number of `inotify` watches and queued events as the default limit can be too low. To increase the limit, run:

```
sysctl fs.inotify.max_user_watches=494462
```

This will increase the limit to 494462 watches and queued events. These lines can be added to `/etc/sysctl.conf` to make the changes persistent.

Note that each watch is a structure in the Kernel, thus available memory is also a bottleneck for using inotify. In fact, a watch can take up to 1KB of space. This means a million watches could result in 1GB of extra RAM usage.

Example: TCP echo-server tcp-server

1. Save this code to a file.
2. Execute it with ":luafile %".
3. Note the port number.
4. Connect from any TCP client (e.g. "nc 0.0.0.0 36795"):

```
local function create_server(host, port, on_connect)
  local server = vim.uv.new_tcp()
  server:bind(host, port)
  server:listen(128, function(err)
    assert(not err, err)  -- Check for errors.
    local sock = vim.uv.new_tcp()
    server:accept(sock)  -- Accept client connection.
    on_connect(sock)  -- Start reading messages.
  end)
  return server
end
local server = create_server('0.0.0.0', 0, function(sock)
  sock:read_start(function(err, chunk)
    assert(not err, err)  -- Check for errors.
    if chunk then
      sock:write(chunk)  -- Echo received messages to the channel.
    else  -- EOF (stream closed).
      sock:close()  -- Always close handles to avoid leaks.
    end
  end)
end)
print('TCP echo-server listening on port: '..server:getsockname().port)
```

Multithreading lua-loop-threading

Plugins can perform work in separate (os-level) threads using the threading APIs in luv, for instance `vim.uv.new_thread`. Each thread has its own separate Lua interpreter state, with no access to Lua globals on the main thread. Neither can the editor state (buffers, windows, etc) be directly accessed from threads.

A subset of the `vim.*` stdlib is available in threads, including:

- `vim.uv` with a separate event loop per thread.
- `vim.mpack` and `vim.json` (useful for serializing messages between threads)
- `require` in threads can use Lua packages from the global package.path
- `print()` and `vim.inspect`
- `vim.text.diff`
- Most utility functions in `vim.*` that work with pure Lua values, like `vim.split`, `vim.tbl_*`, `vim.list_*`, etc.
- `vim.is_thread()` returns true from a non-main thread.

VIM vim.builtin

vim.api.{func}({...}) vim.api
Invokes Nvim API function `{func}` with arguments `{...}`. Example: call the "nvim_get_current_line()" API function:

```
print(tostring(vim.api.nvim_get_current_line()))
```

vim.NIL vim.NIL
Special value representing NIL in RPC and v:null in Vimscript conversion, and similar cases. Lua `nil` cannot be used as part of a Lua table representing a Dictionary or Array, because it is treated as missing: `{"foo", nil}` is the same as `{"foo"}`.

vim.type_idx vim.type_idx
Type index for use in lua-special-tbl. Specifying one of the values from vim.types allows typing the empty table (it is unclear whether empty Lua table represents empty list or empty array) and forcing integral numbers to be Float. See lua-special-tbl for more details.

vim.val_idx vim.val_idx
Value index for tables representing Floats. A table representing floating-point value 1.0 looks like this:

```
{
  [vim.type_idx] = vim.types.float,
  [vim.val_idx] = 1.0,
}
```

See also vim.type_idx and lua-special-tbl.

vim.types vim.types
Table with possible values for vim.type_idx. Contains two sets of key-value pairs: first maps possible values for vim.type_idx to human-readable strings, second maps human-readable type names to values for vim.type_idx. Currently contains pairs for `float`, `array` and `dictionary` types.

Note: One must expect that values corresponding to `vim.types.float`, `vim.types.array` and `vim.types.dictionary` fall under only two following assumptions:

1. Value may serve both as a key and as a value in a table. Given the properties of Lua tables this basically means “value is not `nil`”.
2. For each value in `vim.types` table `vim.types[vim.types[value]]` is the same as `value`. No other restrictions are put on types, and it is not guaranteed that values corresponding to `vim.types.float`, `vim.types.array` and `vim.types.dictionary` will not change or that `vim.types` table will only contain values for these three types.

log_levels vim.log.levels Log levels are one of the values defined in `vim.log.levels`:

vim.log.levels.DEBUG vim.log.levels.ERROR vim.log.levels.INFO vim.log.levels.TRACE vim.log.levels.WARN vim.log.levels.OFF

vim.empty_dict() vim.empty_dict()
Creates a special empty table (marked with a metatable), which Nvim converts to an empty dictionary when translating Lua values to Vimscript or API types. Nvim by default converts an empty table {} without this metatable to an list/array.

Note: If numeric keys are present in the table, Nvim ignores the metatable marker and converts the dict to a list/array anyway.

Return:

(table)

vim.iconv({str}, {from}, {to}) vim.iconv()
The result is a String, which is the text {str} converted from encoding {from} to encoding {to}. When the conversion fails nil is returned. When some characters could not be converted they are replaced with "?". The encoding names are whatever the iconv() library function can accept, see ":Man 3 iconv".

Parameters:
- {str} (string) Text to convert
- {from} (string) Encoding of {str}
- {to} (string) Target encoding

Return:
(string?) Converted string if conversion succeeds, nil otherwise.

vim.in_fast_event() vim.in_fast_event()
Returns true if the code is executing as part of a "fast" event handler, where most of the API is disabled. These are low-level events (e.g. lua-loop-callbacks) which can be invoked whenever Nvim polls for input. When this is false most API functions are callable (but may be subject to other restrictions such as textlock).

vim.rpcnotify({channel}, {method}, {...}) vim.rpcnotify()
Sends {event} to {channel} via RPC and returns immediately. If {channel} is 0, the event is broadcast to all channels.

This function also works in a fast callback lua-loop-callbacks.

Parameters:
- {channel} (integer)
- {method} (string)
- {...} (any?)

vim.rpcrequest({channel}, {method}, {...}) vim.rpcrequest()
Invokes RPC method on channel and blocks until a response is received.

Note: Msgpack NIL values in the response are represented as vim.NIL.

Example: see nvim_exec_lua()

Parameters:
- {channel} (integer)
- {method} (string)
- {...} (any?)

vim.schedule({fn}) vim.schedule()
Schedules {fn} to be invoked soon by the main event-loop. Useful to avoid textlock or other temporary restrictions.

Parameters:
- {fn} (fun())

Return (multiple):
(nil) result (string?) err Error message if scheduling failed, nil otherwise.

vim.str_utf_end({str}, {index}) vim.str_utf_end()
Gets the distance (in bytes) from the last byte of the codepoint (character) that {index} points to.

Examples:

```
-- The character 'æ' is stored as the bytes '\xc3\xa6' (using UTF-8)

-- Returns 0 because the index is pointing at the last byte of a character
vim.str_utf_end('æ', 2)

-- Returns 1 because the index is pointing at the penultimate byte of a character
vim.str_utf_end('æ', 1)
```

Parameters:
- {str} (string)
- {index} (integer)

Return:
(integer)

vim.str_utf_pos({str}) vim.str_utf_pos()
Gets a list of the starting byte positions of each UTF-8 codepoint in the given string.

Embedded NUL bytes are treated as terminating the string.

Parameters:
- {str} (string)

Return:
(integer[])

vim.str_utf_start({str}, {index}) vim.str_utf_start()
Gets the distance (in bytes) from the starting byte of the codepoint (character) that {index} points to.

The result can be added to {index} to get the starting byte of a character.

Examples:

```
-- The character 'æ' is stored as the bytes '\xc3\xa6' (using UTF-8)

-- Returns 0 because the index is pointing at the first byte of a character
vim.str_utf_start('æ', 1)

-- Returns -1 because the index is pointing at the second byte of a character
vim.str_utf_start('æ', 2)
```

Parameters:
- {str} (string)
- {index} (integer)

Return:
(integer)

vim.stricmp({a}, {b}) vim.stricmp()
Compares strings case-insensitively.

Parameters:
- {a} (string)
- {b} (string)

Return:
(0|1|-1) if strings are equal, {a} is greater than {b} or {a} is lesser than {b}, respectively.

vim.ui_attach({ns}, {opts}, {callback}) vim.ui_attach()
WARNING: This feature is experimental/unstable.

Subscribe to ui-events, similar to nvim_ui_attach() but receive events in a Lua callback. Used to implement screen elements like popupmenu or message handling in Lua.

{callback} receives event name plus additional parameters. See ui-popupmenu and the sections below for event format for respective events.

Callbacks for msg_show events originating from internal messages (as opposed to events from commands or API calls) are executed in api-fast context; showing the message needs to be scheduled.

Excessive errors inside the callback will result in forced detachment.

WARNING: This api is considered experimental. Usability will vary for different screen elements. In particular ext_messages behavior is subject to further changes and usability improvements. This is expected to be used to handle messages when setting 'cmdheight' to zero (which is likewise experimental).

Example (stub for a ui-popupmenu implementation):

```
ns = vim.api.nvim_create_namespace('my_fancy_pum')

vim.ui_attach(ns, {ext_popupmenu=true}, function(event, ...)
  if event == 'popupmenu_show' then
    local items, selected, row, col, grid = ...
    print('display pum ', #items)
  elseif event == 'popupmenu_select' then
    local selected = ...
    print('selected', selected)
  elseif event == 'popupmenu_hide' then
    print('FIN')
  end
end)
```

Parameters:
- {ns} (integer) Namespace ID
- {opts} (table<string, any>) Optional parameters.
  - {ext_…}? (boolean) Any of ui-ext-options, if true enable events for the respective UI element.
  - {set_cmdheight}? (boolean) If false, avoid setting 'cmdheight' to 0 when ext_messages is enabled.
- {callback} (fun(event: string, ...): any) Function called for each UI event. A truthy return value signals to Nvim that the event is handled, in which case it is not propagated to remote UIs.

vim.ui_detach({ns}) vim.ui_detach()
Detach a callback previously attached with vim.ui_attach() for the given namespace {ns}.

Parameters:
- {ns} (integer) Namespace ID

LUA-VIMSCRIPT BRIDGE lua-vimscript

Nvim Lua provides an interface or "bridge" to Vimscript variables and functions, and editor commands and options.

Objects passed over this bridge are COPIED (marshalled): there are no "references". lua-guide-variables For example, using vim.fn.remove() on a Lua list copies the list object to Vimscript and does NOT modify the Lua list:

```
local list = { 1, 2, 3 }
vim.fn.remove(list, 0)
vim.print(list)  --> "{ 1, 2, 3 }"
```

vim.call({func}, {...}) vim.call()
Invokes vim-function or user-function {func} with arguments {...}. See also vim.fn. Equivalent to:

```
vim.fn[func]({...})
```

vim.cmd({command}) See vim.cmd().

vim.fn.{func}({...}) vim.fn

Invokes vim-function or user-function {func} with arguments {...}. To call autoload functions, use the syntax:

```
vim.fn['some#function']({...})
```

Unlike vim.api.nvim_call_function() this converts directly between Vim objects and Lua objects. If the Vim function returns a float, it will be represented directly as a Lua number. Empty lists and dictionaries both are represented by an empty table.

Note: v:null values as part of the return value is represented as vim.NIL special value

Note: vim.fn keys are generated lazily, thus `pairs(vim.fn)` only enumerates functions that were called at least once.

Note: The majority of functions cannot run in api-fast callbacks with some undocumented exceptions which are allowed.

lua-vim-variables

The Vim editor global dictionaries g: w: b: t: v: can be accessed from Lua conveniently and idiomatically by referencing the `vim.*` Lua tables described below. In this way you can easily read and modify global Vimscript variables from Lua.

Example:

```
vim.g.foo = 5     -- Set the g:foo Vimscript variable.
print(vim.g.foo)  -- Get and print the g:foo Vimscript variable.
vim.g.foo = nil   -- Delete (:unlet) the Vimscript variable.
vim.b[2].foo = 6  -- Set b:foo for buffer 2
```

Note that setting dictionary fields directly will not write them back into Nvim. This is because the index into the namespace simply returns a copy. Instead the whole dictionary must be written as one. This can be achieved by creating a short-lived temporary.

Example:

```
vim.g.my_dict.field1 = 'value'  -- Does not work

local my_dict = vim.g.my_dict   --
my_dict.field1 = 'value'        -- Instead do
vim.g.my_dict = my_dict         --
```

vim.g vim.g

Global (g:) editor variables. Key with no value returns `nil`.

vim.b vim.b

Buffer-scoped (b:) variables for the current buffer. Invalid or unset key returns `nil`. Can be indexed with an integer to access variables for a specific buffer.

vim.w vim.w

Window-scoped (w:) variables for the current window. Invalid or unset key returns `nil`. Can be indexed with an integer to access variables for a specific window.

vim.t vim.t

Tabpage-scoped (t:) variables for the current tabpage. Invalid or unset key returns `nil`. Can be indexed with an integer to access variables for a specific tabpage.

vim.v vim.v

v: variables. Invalid or unset key returns `nil`.

lua-options
lua-vim-options
lua-vim-set
lua-vim-setlocal

Vim options can be accessed through vim.o, which behaves like Vimscript :set.

Examples:

To set a boolean toggle: Vimscript: `set number` Lua: `vim.o.number = true`

To set a string value: Vimscript: `set wildignore=*.o,*.a,__pycache__` Lua: `vim.o.wildignore = '*.o,*.a,__pycache__'` Lua (alt): `vim.o.wildignore = { '*.o', '*.a', '__pycache__' }`

To set a key:value type option: Vimscript: `set listchars=eol:~,space:-` Lua: `vim.o.listchars = 'eol:~,space:-'` Lua (alt): `vim.o.listchars = { eol = '~', space = '-' }`

Similarly, there is vim.bo and vim.wo for setting buffer-scoped and window-scoped options. Note that this must NOT be confused with local-options and :setlocal. There is also vim.go that only accesses the global value of a global-local option, see :setglobal.

vim.opt_local
vim.opt_global
vim.opt

A special interface vim.opt exists for conveniently interacting with list- and map-style options from Lua: It allows accessing them as Lua tables and offers object-oriented method for adding and removing entries.

Examples:

The following methods of setting a list-style option are equivalent: In Vimscript:

```
set wildignore=*.o,*.a,__pycache__
```

In Lua using `vim.o`:

```
vim.o.wildignore = '*.o,*.a,__pycache__'
```

In Lua using `vim.opt`:

```
vim.opt.wildignore = { '*.o', '*.a', '__pycache__' }
```

To replicate the behavior of :set+=, use:

```

vim.opt.wildignore:append { "*.pyc", "node_modules" }
```

To replicate the behavior of :set^=, use:

```

vim.opt.wildignore:prepend { "new_first_value" }
```

To replicate the behavior of :set-=, use:

```

vim.opt.wildignore:remove { "node_modules" }
```

The following methods of setting a map-style option are equivalent: In Vimscript:

```
set listchars=space:_,tab:>~
```

In Lua using `vim.o`:

```
vim.o.listchars = 'space:_,tab:>~'
```

In Lua using `vim.opt`:

```
vim.opt.listchars = { space = '_', tab = '>~' }
```

Note that vim.opt returns an `Option` object, not the value of the option, which is accessed through vim.opt:get():

Examples:

The following methods of getting a list-style option are equivalent: In Vimscript:

```
echo wildignore
```

In Lua using `vim.o`:

```
print(vim.o.wildignore)
```

In Lua using `vim.opt`:

```
vim.print(vim.opt.wildignore:get())
```

In any of the above examples, to replicate the behavior :setlocal, use `vim.opt_local`. Additionally, to replicate the behavior of :setglobal, use `vim.opt_global`.

Option:append({value}) vim.opt:append()
Append a value to string-style options. See :set+=

These are equivalent:

```
vim.opt.formatoptions:append('j')
vim.opt.formatoptions = vim.opt.formatoptions + 'j'
```

Parameters:

- {value} (`string`) Value to append

Option:get() vim.opt:get()
Returns a Lua-representation of the option. Boolean, number and string values will be returned in exactly the same fashion.

For values that are comma-separated lists, an array will be returned with the values as entries in the array:

```
vim.cmd [[set wildignore=*.pyc,*.o]]

vim.print(vim.opt.wildignore:get())
-- { "*.pyc", "*.o", }

for _, ignore_pattern in ipairs(vim.opt.wildignore:get()) do
    print("Will ignore:", ignore_pattern)
end
-- Will ignore: *.pyc
-- Will ignore: *.o
```

For values that are comma-separated maps, a table will be returned with the names as keys and the values as entries:

```
vim.cmd [[set listchars=space:_,tab:>~]]

vim.print(vim.opt.listchars:get())
--  { space = "_", tab = ">~", }

for char, representation in pairs(vim.opt.listchars:get()) do
    print(char, "=>", representation)
end
```

For values that are lists of flags, a set will be returned with the flags as keys and `true` as entries.

```
vim.cmd [[set formatoptions=njtcroql]]

vim.print(vim.opt.formatoptions:get())
-- { n = true, j = true, c = true, ... }

local format_opts = vim.opt.formatoptions:get()
if format_opts.j then
    print("J is enabled!")
end
```

Return:
(`string|integer|boolean|string[]|table<string,string|boolean>?`) value of option

Option:prepend({value}) vim.opt:prepend()
Prepend a value to string-style options. See :set^=

These are equivalent:

```
vim.opt.wildignore:prepend('*.o')
vim.opt.wildignore = vim.opt.wildignore ^ '*.o'
```

Parameters:
- {value} (`string`) Value to prepend

Option:remove({value}) vim.opt:remove()
Remove a value from string-style options. See :set-=

These are equivalent:

```
vim.opt.wildignore:remove('*.pyc')
vim.opt.wildignore = vim.opt.wildignore - '*.pyc'
```

Parameters:
- {value} (`string`) Value to remove

vim.bo[{bufnr}] vim.bo
Gets or sets buffer-scoped options on buffer {bufnr} (or "current buffer" if 0 or omitted). Like `:setlocal`. Invalid {bufnr} or key is an error.

Example:

```
local bufnr = vim.api.nvim_get_current_buf()
vim.bo[bufnr].buflisted = true    -- same as vim.bo.buflisted = true
print(vim.bo.comments)
print(vim.bo.baz)                 -- error: invalid key
```

vim.env vim.env
Gets or sets environment variables in the current editor process. See expand-env and :let-environment for the Vimscript behavior. Invalid or unset key returns `nil`.

Example:

```
vim.env.FOO = 'bar'
print(vim.env.TERM)
```

vim.go vim.go
Gets or sets global options. Like `:setglobal`. Invalid key is an error.

Note: unlike vim.o, this accesses the global option value and thus is mostly useful with global-local options.

Example:

```
vim.go.cmdheight = 4
print(vim.go.columns)
print(vim.go.bar)     -- error: invalid key
```

vim.o vim.o
Gets or sets options. Works like `:set`, so buffer/window-scoped options target the current buffer/window. Invalid key is an error.

Example:

```
vim.o.cmdheight = 4
print(vim.o.columns)
print(vim.o.foo)     -- error: invalid key
```

vim.wo[{winid}][{bufnr}] vim.wo
Gets or sets window-scoped options on window {winid} (or "current window" if 0 or omitted) and buffer {bufnr} (0 for current buffer). Like `:setlocal` if setting a global-local option or if {bufnr} is specified, like `:set` otherwise. Invalid {winid}, {bufnr}, or key is an error.

Note: only bufnr=0 (current window-buffer) is supported, currently.

Example:

```
local winid = vim.api.nvim_get_current_win()
vim.wo[winid].number = true    -- same as vim.wo.number = true
print(vim.wo.foldmarker)
print(vim.wo.quux)             -- error: invalid key
vim.wo[winid][0].spell = false -- like ':setlocal nospell'
```

Lua module: vim

vim.Ringbuf

Fields:

- {clear} (fun()) See Ringbuf:clear().
- {peek} (fun(): T?) See Ringbuf:peek().
- {pop} (fun(): T?) See Ringbuf:pop().
- {push} (fun(item: T)) See Ringbuf:push().

Ringbuf:clear() Ringbuf:clear()
Clear all items

Ringbuf:peek() Ringbuf:peek()
Returns the first unread item without removing it

Return:
(T?)

Ringbuf:pop() Ringbuf:pop()
Removes and returns the first unread item

Return:
(T?)

Ringbuf:push({item}) Ringbuf:push()
Adds an item, overriding the oldest item if the buffer is full.

Parameters:

- {item} (T)

vim.cmd({cmd}) vim.cmd()
Executes Vimscript (Ex-commands).

Can be indexed with a command name to get a function, thus you can write vim.cmd.echo(…) instead of vim.cmd{cmd='echo',…}.

Examples:

```
-- Single command:
vim.cmd('echo 42')
-- Multiline script:
vim.cmd([[
  augroup my.group
    autocmd!
    autocmd FileType c setlocal cindent
  augroup END
]])

-- Ex command :echo "foo". Note: string literals must be double-quoted.
vim.cmd('echo "foo"')
vim.cmd { cmd = 'echo', args = { '"foo"' } }
vim.cmd.echo({ args = { '"foo"' } })
vim.cmd.echo('"foo"')

-- Ex command :write! myfile.txt
vim.cmd('write! myfile.txt')
vim.cmd { cmd = 'write', args = { 'myfile.txt' }, bang = true }
vim.cmd.write { args = { 'myfile.txt' }, bang = true }
vim.cmd.write { 'myfile.txt', bang = true }

-- Ex command :vertical resize +2
vim.cmd.resize({ '+2', mods = { vertical = true } })

-- Pass arg literally, without needing to escape special chars:
vim.cmd.edit({ '%foo"|bar#baz"', magic = { file = false, bar = false } })
```

Parameters:

- {cmd} (string|table) Command(s) to execute.
  - The string form supports multiline Vimscript (alias to nvim_exec2(), behaves like :source).
  - The table form executes a single command (alias to nvim_cmd()).

See also:

- ex-cmd-index

vim.deep_equal({a}, {b}) vim.deep_equal()
Deep compare values for equality

Tables are compared recursively unless they both provide the eq metamethod. All other types are compared using the equality == operator. Cyclic tables are supported.

Parameters:

- {a} (any) First value

- {b} (any) Second value

Return:
(boolean) `true` if values are equals, else `false`

vim.deepcopy({orig}, {noref}) vim.deepcopy()
Returns a deep copy of the given object. Non-table objects are copied as in a typical Lua assignment, whereas table objects are copied recursively. Functions are naively copied, so functions in the copied table point to the same functions as those in the input table. Userdata and threads are not copied and will throw an error.

Note: `noref=true` is much more performant on tables with unique table fields, while `noref=false` is more performant on tables that reuse table fields.

Parameters:
- {orig} (table) Table to copy
- {noref} (boolean?) When `false` (default) a contained table is only copied once and all references point to this single copy. When `true` every occurrence of a table results in a new copy. This also means that a cyclic reference can cause `deepcopy()` to fail.

Return:
(table) Table of copied keys and (nested) values.

vim.defaulttable({createfn}) vim.defaulttable()
Creates a table whose missing keys are provided by {createfn} (like Python's "defaultdict").

If {createfn} is `nil` it defaults to defaulttable() itself, so accessing nested keys creates nested tables:

```
local a = vim.defaulttable()
a.b.c = 1
```

Parameters:
- {createfn} (fun(key:any):any?) Provides the value for a missing key.

Return:
(table) Empty table with `__index` metamethod.

vim.defer_fn({fn}, {timeout}) vim.defer_fn()
Defers calling {fn} until {timeout} ms passes.

Use to do a one-shot timer that calls {fn}. **Note:** The {fn} is scheduled automatically, so API functions are safe to call.

Parameters:
- {fn} (function) Callback to call once `timeout` expires
- {timeout} (integer) Number of milliseconds to wait before calling `fn`

Return:
(uv.uv_timer_t) timer luv timer object

vim.deprecate() vim.deprecate({name}, {alternative}, {version}, {plugin}, {backtrace}) Shows a deprecation message to the user.

Parameters:
- {name} (string) **Deprecated** feature (function, API, etc.).
- {alternative} (string?) Suggested alternative feature.
- {version} (string) Version when the deprecated function will be removed.
- {plugin} (string?) Name of the plugin that owns the deprecated feature. Defaults to "Nvim".
- {backtrace} (boolean?) Prints backtrace. Defaults to true.

Return:
(string?) Deprecation message, or nil if no message was shown.

vim.endswith({s}, {suffix}) vim.endswith()
Tests if s ends with `suffix`.

Parameters:
- {s} (string) String
- {suffix} (string) Suffix to match

Return:
(boolean) `true` if `suffix` is a suffix of s

vim.gsplit({s}, {sep}, {opts}) vim.gsplit()
Gets an iterator that splits a string at each instance of a separator, in "lazy" fashion (as opposed to vim.split() which is "eager").

Example:

```
for s in vim.gsplit(':aa::b:', ':', {plain=true}) do
  print(s)
end
```

If you want to also inspect the separator itself (instead of discarding it), use string.gmatch(). Example:

```
for word, num in ('foo111bar222'):gmatch('([^0-9]*)(%d*)') do
  print(('word: %s num: %s'):format(word, num))
end
```

Parameters:
- {s} (string) String to split
- {sep} (string) Separator or pattern
- {opts} (table?) Keyword arguments kwargs:
  - {plain}? (boolean) Use sep literally (as in string.find).

- `{trimempty}`? (`boolean`) Discard empty segments at start and end of the sequence.

Return:
(`fun():string`?) Iterator over the split components

See also:
- string.gmatch()
- vim.split()
- lua-patterns
- https://www.lua.org/pil/20.2.html
- http://lua-users.org/wiki/StringLibraryTutorial

vim.inspect({`root`}, {`options`}) vim.inspect()
Gets a human-readable representation of the given object.

Parameters:
- `{root}` (`any`)
- `{options}` (`table`?) A table with the following fields:
  - `{depth}`? (`integer`, default: unlimited) Maximum table nesting depth. Deeper tables are shown as `{...}`.
  - `{indent}`? (`string`, default: `"  "`) String repeated for each level of indentation.
  - `{newline}`? (`string`, default: `"\n"`) String used for line breaks.
  - `{process}`? (`fun(item: any, path: any[]): any`) Transforms values, keys, and metatables before formatting. Return a replacement value, or `nil` to omit a table entry. `{path}` lists the keys leading to `{item}`, with `vim.inspect.KEY` appended for keys or `vim.inspect.METATABLE` for metatables. The root has an empty path.

Return:
(`string`)

See also:
- vim.print()
- https://github.com/kikito/inspect.lua
- https://github.com/mpeterv/vinspect

vim.is_callable({`f`}) vim.is_callable()
Returns true if object `f` can be called as a function.

Parameters:
- `{f}` (`any`?) Any object

Return:
(`boolean`) `true` if `f` is callable, else `false`

vim.isarray({`t`}) vim.isarray()
Tests if `t` is an "array": a table indexed only by integers (potentially non-contiguous).

If the indexes start from 1 and are contiguous then the array is also a list. vim.islist()

Empty table {} is an array, unless it was created by vim.empty_dict() or returned as a dict-like API or Vimscript result, for example from rpcrequest() or vim.fn.

Parameters:
- `{t}` (`any`?)

Return:
(`boolean`) `true` if array-like table, else `false`.

See also:
- https://github.com/openresty/luajit2#tableisarray

vim.islist({`t`}) vim.islist()
Tests if `t` is a "list": a table indexed only by contiguous integers starting from 1 (what lua-length calls a "regular array").

Empty table {} is a list, unless it was created by vim.empty_dict() or returned as a dict-like API or Vimscript result, for example from rpcrequest() or vim.fn.

Parameters:
- `{t}` (`any`?)

Return:
(`boolean`) `true` if list-like table, else `false`.

See also:
- vim.isarray()

vim.isnil({`t`}) vim.isnil()
Tests if `t` is `nil` or vim.NIL.

Attributes:
Since: 0.13.0

Parameters:
- `{t}` (`any`?)

Return:
(`boolean`) `true` if `nil` or vim.NIL, else `false`.

vim.keycode({`keys`}, {`info`}) vim.keycode()
Converts keys from key-notation to the internal encoding. Optionally returns structured key-chord info as retval 2.

Inverse of keytrans(), which converts the internal encoding back to key-notation.

Examples:

```
local k = vim.keycode
vim.g.mapleader = k'<bs>'

-- Split a key sequence into chords, e.g. to inspect modifiers.
local _, chords = vim.keycode('<C-w>v', true)
assert(chords[1].key == 'w' and chords[1].mod[1] == 'C')

-- keytrans() is the inverse: internal encoding => key-notation.
assert(vim.fn.keytrans(vim.keycode('<C-a>')) == '<C-A>')
```

Parameters:
- {keys} (string) Keys in key-notation.
- {info} (boolean?) Also return key-chord info.

Return (multiple):
(string) Internal representation of the given keys. (table?) List of parsed key-chords, each with fields:
- {key} (string) Key without modifiers. Example: <C-A> has key="a".
- {key_alt} (string?) Alternative spelling of key, or nil if There Is No Alternative (TINA). Example: "<" has key_alt="lt".
- {keys} (string) Full key-chord in canonical key-notation (as produced by keytrans()), including modifiers. Example: <A-f> has keys="<M-f>".
- {mod} (('M'|'T'|'C'|'S'|'2'|'3'|'4'|'D')[]) List of key-chord modifiers. Example: <C-S-f> has mod={ 'C', 'S' }.

See also:
- nvim_replace_termcodes()
- keytrans()

vim.list.bisect({t}, {val}, {opts}) vim.list.bisect()
Search for a position in a sorted lua-list {t} where {val} can be inserted while keeping the list sorted.

Use {bound} to determine whether to return the first or the last position, defaults to "lower", i.e., the first position.

With {opts.key}, {val} may differ from the list elements, provided the key function accepts both. For a string key, that field must exist on both. A partial record is sufficient if it contains all fields used by the key.

NOTE: The values being compared must support <, and the list must be sorted by those values (after applying {opts.key}, if provided).

Example:

```
local t = { 1, 2, 2, 3, 3, 3 }
local first = vim.list.bisect(t, 3)
-- `first` is `val`'s first index if found,
-- useful for existence checks.
print(t[first]) -- 3

local last = vim.list.bisect(t, 3, { bound = 'upper' })
-- Note that `last` is 7, not 6,
-- this is suitable for insertion.

table.insert(t, last, 4)
-- t is now { 1, 2, 2, 3, 3, 3, 4 }

-- You can use lower bound and upper bound together
-- to obtain the range of occurrences of `val`.

-- 3 is in [first, last)
for i = first, last - 1 do
  print(t[i]) -- { 3, 3, 3 }
end
```

Attributes:
Since: 0.12.0

Parameters:
- {t} (any[]) A sorted list.
- {val} (any) The value to search.
- {opts} (table?) A table with the following fields:
  - {bound}? ('lower'|'upper', default: 'lower') Specifies the search variant.
    - "lower": returns the first position where inserting {val} keeps the list sorted.
    - "upper": returns the last position where inserting {val} keeps the list sorted..
  - {hi}? (integer, default: #t + 1) End index of the list, exclusive.
  - {key}? ((string & keyof T)|fun(val: T): any) Applied to {val} and the list elements being compared. If a string, index both by this field name. If a function, it must accept both {val} and the list elements and return mutually comparable keys.
  - {lo}? (integer, default: 1) Start index of the list.

Overloads:
- fun<T, Q>(t: T[], val: Q, opts: vim.list.bisect.Opts<T|Q> & { key: fun(val: T|Q): any }): integer
- fun<T: table, Q: table>(t: T[], val: Q, opts: vim.list.bisect.Opts<T|Q> & { key: string & keyof T & keyof Q }): integer

Return:
(integer) index serves as either the lower bound or the upper bound position.

vim.list.unique({t}, {key}) vim.list.unique()
Removes duplicate values from a lua-list in-place.

Only the first occurrence of each value is kept. The operation is performed in-place and the input table is modified.

Accepts an optional key argument, which if provided is called for each value in the list to compute a hash key for uniqueness comparison. If key is a string, it is used as the field name to index each value. This is useful for deduplicating table values or complex objects. If key returns `nil` for a value, that value will be considered unique, even if multiple values return `nil`.

Example:

```
local t = {1, 2, 2, 3, 1}
vim.list.unique(t)
-- t is now {1, 2, 3}

local t = { {id=1}, {id=2}, {id=1} }
vim.list.unique(t, 'id')
-- t is now { {id=1}, {id=2} }
```

Attributes:
Since: 0.12.0

Parameters:
- `{t}` (`any[]`)
- `{key}` (`string|fun(x: T): any?`) Optional field name or hash function to determine uniqueness of values

Return:
(`any[]`) The deduplicated list

See also:
- Iter:unique()

vim.list_contains(`{t}`, `{value}`) vim.list_contains()
Checks if a list-like table (integer keys without gaps) contains `value`.

Parameters:
- `{t}` (`table`) Table to check (must be list-like, not validated)
- `{value}` (any) Value to compare

Return:
(`boolean`) `true` if `t` contains `value`

See also:
- vim.tbl_contains() for checking values in general tables

vim.list_extend(`{dst}`, `{src}`, `{start}`, `{finish}`) vim.list_extend()
Extends a list-like table with the values of another list-like table.

NOTE: This mutates dst!

Parameters:
- `{dst}` (`table`) List which will be modified and appended to
- `{src}` (`table`) List from which values will be inserted
- `{start}` (`integer?`) (default: 1) Start index on src.
- `{finish}` (`integer?`) (default: `#src`) Final index on src.

Return:
(`table`) dst

See also:
- vim.tbl_extend()

vim.list_slice(`{list}`, `{start}`, `{finish}`) vim.list_slice()
Creates a copy of a table containing only elements from start to end (inclusive)

Parameters:
- `{list}` (`any[]`) Table
- `{start}` (`integer?`) Start range of slice
- `{finish}` (`integer?`) End range of slice

Return:
(`any[]`) Copy of table sliced from start to finish (inclusive)

vim.lua_omnifunc(`{find_start}`) vim.lua_omnifunc()
Omnifunc for completing Lua values from the runtime Lua interpreter, similar to the builtin completion for the `:lua` command.

Activate using `vim.bo.omnifunc = vim.lua_omnifunc` in a Lua buffer.

Parameters:
- `{find_start}` (`1|0`)

vim.nonnil(`{...}`) vim.nonnil()
Returns the first argument which is not nil.

If all arguments are nil, returns nil.

Example:

```
local a = nil
local b = nil
local c = 42
local d = true
assert(vim.nonnil(a, b, c, d) == 42)
```

Attributes:
Since: 0.13.0

Parameters:
- `{...}` (any)

Return:
(any)

vim.notify({msg}, {level}, {opts}) vim.notify()
Displays a notification to the user.

This function can be overridden by plugins to display notifications using a custom provider (such as the system notification provider). By default, writes to :messages.

Parameters:
- `{msg}` (`string`) Content of the notification to show to the user.
- `{level}` (`integer?`) One of the values from vim.log.levels.
- `{opts}` (`table?`) Optional parameters. Unused by default.

vim.notify_once({msg}, {level}, {opts}) vim.notify_once()
Displays a notification only one time.

Like vim.notify(), but subsequent calls with the same message will not display a notification.

Parameters:
- `{msg}` (`string`) Content of the notification to show to the user.
- `{level}` (`integer?`) One of the values from vim.log.levels.
- `{opts}` (`table?`) Optional parameters. Unused by default.

Return:
(`boolean`) true if message was displayed, else false

vim.npcall({fn}, {...}) vim.npcall()
Calls the function `fn` in `protected mode` like pcall(), but returns `nil` on error.

Attributes:
Since: 0.13.0

Parameters:
- `{fn}` (`fun(...):T`)
- `{...}` (`any?`)

Return:
(any) ...

vim.on_key({fn}, {ns_id}, {opts}) vim.on_key()
Registers function `{fn}` with namespace `{ns_id}` as a listener to EVERY input key (except keys consumed by getchar(), by `{fn}` itself, or by a `<Cmd>` payload).

To parse key-chords, see vim.keycode(). Example:

```
local keychords = vim.keycode(vim.fn.keytrans(key), true)
```

Note:
- If `{fn}` returns an empty string, `{key}` is discarded/ignored; if `{key}` is `<Cmd>` then the "`<Cmd>`…`<CR>`" sequence is discarded as a whole.
- Non-recursive: if `{fn}` itself consumes input, it won't be invoked for those keys.
- Not invoked for keys consumed by getchar()/getcharstr(): they never reach the main loop.
- To UNregister a given `{ns_id}`, pass `nil` `{fn}`.
- `{fn}` will be removed on error.
- `{fn}` will not be cleared by nvim_buf_clear_namespace()
- The -w command-line option is related but does not support callbacks and cannot be toggled dynamically.

Parameters:
- `{fn}` (`fun(key: string, typed: string): string??`) Function invoked for every input key, after mappings have been applied but before further processing. Arguments `{key}` and `{typed}` are raw input (use keytrans() to get keycodes).
  - `{key}` is the key after mappings are applied.
  - `{typed}` is the input before mappings are applied; may be empty if `{key}` was produced by non-typed key(s) or by the same typed key(s) that produced a previous `{key}`.
- `{ns_id}` (`integer?`) Namespace ID. If nil or 0, returns a new namespace id.
- `{opts}` (`table?`) Optional parameters

Return:
(`integer`) Namespace id associated with `{fn}`. Or count of all callbacks if on_key() is called without arguments.

See also:
- keytrans()
- vim.keycode()

vim.paste({lines}, {phase}) vim.paste()
Paste handler, invoked by nvim_paste().

Note: This is provided only as a "hook", don't call it directly; call nvim_paste() instead, which arranges redo (dot-repeat) and invokes `vim.paste`.

Example: To remove ANSI color codes when pasting:

```
vim.paste = (function(overridden)
  return function(lines, phase)
    for i,line in ipairs(lines) do
      -- Scrub ANSI color codes from paste input.
      lines[i] = line:gsub('\27%[[0-9;mK]+', '')
    end
    return overridden(lines, phase)
  end
end)(vim.paste)
```

Parameters:
- {lines} (string[]) readfile()-style list of lines to paste. channel-lines
- {phase} (-1|1|2|3) -1: "non-streaming" paste: the call contains all lines. If paste is "streamed", phase indicates the stream state:
  - 1: starts the paste (exactly once)
  - 2: continues the paste (zero or more times)
  - 3: ends the paste (exactly once)

Return:
(boolean) result false if client should cancel the paste.

See also:
- paste

vim.pesc({s}) vim.pesc()
Escapes magic chars in lua-patterns.

Parameters:
- {s} (string) String to escape

Return:
(string) %-escaped pattern string

See also:
- https://github.com/rxi/lume

vim.print({...}) vim.print()
"Pretty prints" the given arguments and returns them unmodified.

Example:

```
local hl_normal = vim.print(vim.api.nvim_get_hl(0, { name = 'Normal' }))
```

Parameters:
- {...} (any)

Return:
(any) given arguments.

See also:
- vim.inspect()
- :=

vim.ringbuf({size}) vim.ringbuf()
Create a ring buffer limited to a maximal number of items. Once the buffer is full, adding a new entry overrides the oldest entry.

```
local ringbuf = vim.ringbuf(4)
ringbuf:push("a")
ringbuf:push("b")
ringbuf:push("c")
ringbuf:push("d")
ringbuf:push("e")    -- overrides "a"
print(ringbuf:pop()) -- returns "b"
print(ringbuf:pop()) -- returns "c"

-- Can be used as iterator. Pops remaining items:
for val in ringbuf do
  print(val)
end
```

Returns a Ringbuf instance with the following methods:
- Ringbuf:push()
- Ringbuf:pop()
- Ringbuf:peek()
- Ringbuf:clear()

Parameters:
- {size} (integer)

Return:
(vim.Ringbuf<any>) ringbuf

vim.schedule_wrap({fn}) vim.schedule_wrap()
Returns a function which calls {fn} via vim.schedule().

The returned function passes all arguments to {fn}.

Example:

```
function notify_readable(_err, readable)
  vim.notify("readable? " .. tostring(readable))
end
vim.uv.fs_access(vim.fn.stdpath("config"), "R", vim.schedule_wrap(notify_readable))
```

Parameters:
- {fn} (function)

Return:
(function)

See also:
- lua-loop-callbacks
- vim.schedule()
- vim.in_fast_event()

vim.spairs({t}) vim.spairs()
Enumerates key-value pairs of a table, ordered by key.

Parameters:
- {t} (table) Dict-like table

Return (multiple):
(fun(table: table<K, V>, index?: K):K, V) for-in iterator over sorted keys and their values (table)

See also:
- Based on https://github.com/premake/premake-core/blob/master/src/base/table.lua

vim.split({s}, {sep}, {opts}) vim.split()
Splits a string at each instance of a separator and returns the result as a table (unlike vim.gsplit()).

Examples:

```
split(":aa::b:", ":")                   --> {'','aa','','b',''}
split("axaby", "ab?")                   --> {'','x','y'}
split("x*yz*o", "*", {plain=true})      --> {'x','yz','o'}
split("|x|y|z|", "|", {trimempty=true}) --> {'x', 'y', 'z'}
```

Parameters:
- {s} (string) String to split
- {sep} (string) Separator or pattern
- {opts} (table?) Keyword arguments kwargs:
  - {plain}? (boolean) Use sep literally (as in string.find).
  - {trimempty}? (boolean) Discard empty segments at start and end of the sequence.

Return:
(string[]) List of split components

See also:
- vim.gsplit()
- string.gmatch()

vim.startswith({s}, {prefix}) vim.startswith()
Tests if s starts with prefix.

Parameters:
- {s} (string) String
- {prefix} (string) Prefix to match

Return:
(boolean) true if prefix is a prefix of s

vim.str_byteindex()
vim.str_byteindex({s}, {encoding}, {index}, {strict_indexing}) Convert UTF-32, UTF-16 or UTF-8 {index} to byte index. If {strict_indexing} is false then an out of range index will return byte length instead of throwing an error.

Invalid UTF-8 and NUL is treated like in vim.str_utfindex(). An {index} in the middle of a UTF-16 sequence is rounded upwards to the end of that sequence.

Parameters:
- {s} (string)
- {encoding} ("utf-8"|"utf-16"|"utf-32")
- {index} (integer)
- {strict_indexing} (boolean?) default: true

Return:
(integer)

vim.str_utfindex()
vim.str_utfindex({s}, {encoding}, {index}, {strict_indexing}) Convert byte index to UTF-32, UTF-16 or UTF-8 indices. If {index} is not supplied, the length of the string is used. All indices are zero-based.

If {strict_indexing} is false then an out of range index will return string length instead of throwing an error. Invalid UTF-8 bytes, and embedded surrogates are counted as one code point each. An {index} in the middle of a UTF-8 sequence is rounded upwards to the end of that sequence.

Parameters:
- {s} (string)
- {encoding} ("utf-8"|"utf-16"|"utf-32")
- {index} (integer?)

- {strict_indexing} (boolean?) default: true

Return:
(integer)

vim.tbl_contains({t}, {value}, {opts}) vim.tbl_contains()
Checks if a table contains a given value, specified either directly or via a predicate that is checked for each value.

Example:

```
vim.tbl_contains({ 'a', { 'b', 'c' } }, function(v)
  return vim.deep_equal(v, { 'b', 'c' })
end, { predicate = true })
-- true
```

Parameters:
- {t} (table) Table to check
- {value} (any) Value to compare or predicate function reference
- {opts} (table?) Keyword arguments kwargs:
  - {predicate}? (boolean, default: false) value is a function reference to be checked

Return:
(boolean) true if t contains value

See also:
- vim.list_contains() for checking values in list-like tables

vim.tbl_count({t}) vim.tbl_count()
Counts the number of non-nil values in table t.

```
vim.tbl_count({ a=1, b=2 })  --> 2
vim.tbl_count({ 1, 2 })      --> 2
```

Parameters:
- {t} (table) Table

Return:
(integer) Number of non-nil values in table

See also:
- https://github.com/Tieske/Penlight/blob/master/lua/pl/tablex.lua

vim.tbl_deep_extend({behavior}, {...}) vim.tbl_deep_extend()
Merges two or more tables recursively.

Only lua-dict tables are merged recursively; lua-list tables are treated as opaque values (overwritten instead of merged). That is convenient for merging default/user configurations where lists typically should not be merged together.

Example:

```
-- Set `config.settings.…` without worrying about whether intermediate dicts exist.
local config = { settings = { tailwindCSS = { foo = 'bar' } } }
local merged = vim.tbl_deep_extend('force',
  config,
  { settings = { tailwindCSS = { experimental = { configFile = '/my/config.json' } } } }
)
vim.print(merged)
```

Parameters:
- {behavior} ('error'|'keep'|'force'|fun(key:any, prev_value:any?, value:any): any) Decides what to do if a key is found in more than one map:
  - "error": raise an error
  - "force": use value from the rightmost map
  - "keep": use value from the leftmost map
  - If a function, it receives the current key, the previous value in the currently merged table (if present), the current value and should return the value for the given key in the merged table.
- {...} (table) Two or more tables

Return:
(table) Merged table

See also:
- vim.tbl_extend()

vim.tbl_extend({behavior}, {...}) vim.tbl_extend()
Merges two or more tables.

Parameters:
- {behavior} ('error'|'keep'|'force'|fun(key:any, prev_value:any?, value:any): any) Decides what to do if a key is found in more than one map:
  - "error": raise an error
  - "force": use value from the rightmost map
  - "keep": use value from the leftmost map
  - If a function, it receives the current key, the previous value in the currently merged table (if present), the current value and should return the value for the given key in the merged table.
- {...} (table) Two or more tables

Return:
(table) Merged table

See also:
- extend()

vim.tbl_filter({fn}, {t}) vim.tbl_filter()
Filter a table using a predicate function

Parameters:
- {fn} (function) Function
- {t} (table) Table

Return:
(any[]) Table of filtered values

vim.tbl_get({o}, {...}) vim.tbl_get()
Gets a (nested) value from table o given by a sequence of keys ..., or nil if not found.

Note: To set deeply nested keys, see vim.tbl_deep_extend().

Example:

```
local o = { a = { b = true } }
-- Get `o.a.b`.
vim.print(vim.tbl_get(o, 'a', 'b')) -- true
o.a = {}
vim.print(vim.tbl_get(o, 'a', 'b')) -- nil
```

Parameters:
- {o} (table) Table to index
- {...} (any) Optional keys (0 or more, variadic) via which to index the table

Return:
(any) Nested value indexed by key (if it exists), else nil

See also:
- unpack()
- vim.tbl_deep_extend()

vim.tbl_isempty({t}) vim.tbl_isempty()
Checks if a table is empty.

Parameters:
- {t} (table) Table to check

Return:
(boolean) true if t is empty

See also:
- https://github.com/premake/premake-core/blob/master/src/base/table.lua

vim.tbl_keys({t}) vim.tbl_keys()
Return a list of all keys used in a table. However, the order of the return table of keys is not guaranteed.

Parameters:
- {t} (table) Table

Return:
(any[]) List of keys

See also:
- From https://github.com/premake/premake-core/blob/master/src/base/table.lua

vim.tbl_map({fn}, {t}) vim.tbl_map()
Applies function fn to all values of table t, in pairs() iteration order (which is not guaranteed to be stable, even when the data doesn't change).

Parameters:
- {fn} (fun(value: T): R) Function
- {t} (table<any, T>) Table

Return:
(table<any, R>) Table of transformed values

vim.tbl_values({t}) vim.tbl_values()
Return a list of all values used in a table. However, the order of the return table of values is not guaranteed.

Parameters:
- {t} (table) Table

Return:
(any[]) List of values

vim.trim({s}) vim.trim()
Trim whitespace (Lua pattern "%s") from both sides of a string.

Parameters:
- {s} (string) String to trim

Return:
(string) String with whitespace removed from its beginning and end

See also:
- lua-patterns
- https://www.lua.org/pil/20.2.html

vim.validate() vim.validate({name}, {value}, {validator}, {optional}, {message}) Validate function arguments.

This function has two valid forms:

1. `vim.validate(name, value, validator[, optional][, message])` Validates that argument {name} with value {value} satisfies {validator}. If {optional} is given and is `true`, then {value} may be `nil`. If {message} is given, then it is used as the expected type in the error message. Example:

```
 function vim.startswith(s, prefix)
  vim.validate('s', s, 'string')
  vim.validate('prefix', prefix, 'string')
  -- ...
end
```

2. `vim.validate(spec)` (DEPRECATED) where spec is of type `table<string,[value:any, validator: vim.validate.Validator, optional_or_msg? : boolean|string]>`) Validates a argument specification. Specs are evaluated in alphanumeric order, until the first failure.

Examples:

```
vim.validate('arg1', {'foo'}, 'table')
   --> NOP (success)
vim.validate('arg2', 'foo', 'string')
   --> NOP (success)

vim.validate('arg1', 1, 'table')
   --> error('arg1: expected table, got number')

vim.validate('arg1', 3, function(a) return (a % 2) == 0 end, 'even number')
   --> error('arg1: expected even number, got 3')

-- If multiple types are valid they can be given as a list:
vim.validate('arg1', {'foo'}, {'table', 'string'})
vim.validate('arg2', 'foo', {'table', 'string'})
-- NOP (success)
vim.validate('arg1', 1, {'string', 'table'})
-- error('arg1: expected string|table, got number')
```

Note:

- `validator` set to a value returned by lua-type() provides the best performance.

Parameters:

- {name} (`string`) Argument name
- {value} (`any`) Argument value
- {validator} (`vim.validate.Validator`)
  - (`string|string[]`): Any value that can be returned from lua-type() in addition to `'callable'`: `'boolean'`, `'callable'`, `'function'`, `'nil'`, `'number'`, `'string'`, `'table'`, `'thread'`, `'userdata'`.
  - (`fun(val:any): boolean, string?`) A function that returns a boolean and an optional string message.
- {optional} (`boolean?`) (default: false) Parameter is optional (may be omitted or nil)
- {message} (`string?`) message when validation fails

Overloads:

- `fun(name: string, val: any, validator: vim.validate.Validator, message: string)`
- `fun(spec: table<string,[any, vim.validate.Validator, boolean|string]>)`

vim.wait({time}, {callback}, {interval}, {fast_only}) vim.wait()
Waits up to `time` milliseconds, until `callback` returns `true` (success). Executes `callback` immediately, then on user events, internal events, and approximately every `interval` milliseconds. Returns `true` plus any remaining callback results on success.

Nvim processes other events while waiting. Cannot be called during an api-fast event.

Examples:

```
-- Wait for 100 ms, allowing other events to process.
vim.wait(100)

-- Wait up to 1000 ms or until `vim.g.foo` is true, at intervals of ~500 ms.
vim.wait(1000, function() return vim.g.foo end, 500)

-- Wait indefinitely until `vim.g.foo` is true, and get the callback results.
local ok, rv1, rv2, rv3 = vim.wait(math.huge, function()
  return vim.g.foo, 'a', 42, { ok = { 'yes' } }
end)

-- Schedule a function to set a value in 100ms. This would wait 10s if blocked, but actually
-- only waits 100ms because `vim.wait` processes other events while waiting.
vim.defer_fn(function() vim.g.timer_result = true end, 100)
if vim.wait(10000, function() return vim.g.timer_result end) then
  print('Only waiting a little bit of time!')
end

-- Yield via vim.wait() to allow CTRL-C to interrupt Lua code.
while true do
  -- ...work...
  local _, code = vim.wait(0, nil, 0)
  if code == -2 then -- CTRL-C.
    break
  end
end
```

Parameters:

- {time} (number) Number of milliseconds to wait. Must be non-negative number, any fractional part is truncated.
- {callback} (fun(): boolean, ...?) Optional callback. Waits until {callback} returns true
- {interval} (integer?) (default: 200) Milliseconds (approximate) to wait between polls.
- {fast_only} (boolean?) If true, only api-fast events will be processed.

Return (multiple):
(boolean) (-1|-2?)

- If callback returns true before timeout: true, ... (remaining callback results).
- On timeout: false, -1
- On interrupt: false, -2
- On error: the error is raised.

Lua module: vim.inspector

vim.inspector

vim.inspect_pos({buf}, {row}, {col}, {filter}) vim.inspect_pos()
Get all the items at a given buffer position.

Can also be pretty-printed with :Inspect!. :Inspect!

Attributes:
Since: 0.9.0

Parameters:

- {buf} (integer?) defaults to the current buffer
- {row} (integer?) row to inspect, 0-based. Defaults to the row of the current cursor
- {col} (integer?) col to inspect, 0-based. Defaults to the col of the current cursor
- {filter} (table?) Table with key-value pairs to filter the items
  - {extmarks} (boolean|"all", default: true) Include extmarks. When all, then extmarks without a hl_group will also be included.
  - {semantic_tokens} (boolean, default: true) Include semantic token highlights.
  - {syntax} (boolean, default: true) Include syntax based highlight groups.
  - {treesitter} (boolean, default: true) Include treesitter based highlight groups.

Return:
(table) a table with the following key-value pairs. Items are in "traversal order":

- treesitter: a list of treesitter captures
- syntax: a list of syntax groups
- semantic_tokens: a list of semantic tokens
- extmarks: a list of extmarks
- buffer: the buffer used to get the items
- row: the row used to get the items
- col: the col used to get the items

vim.show_pos({buf}, {row}, {col}, {filter}) vim.show_pos()
Show all the items at a given buffer position.

Can also be shown with :Inspect. :Inspect

See also :marks to list all extmarks.

Example: To bind this function to the vim-scriptease inspired zS in Normal mode:

```
vim.keymap.set('n', 'zS', vim.show_pos)
```

Attributes:
Since: 0.9.0

Parameters:

- {buf} (integer?) defaults to the current buffer

- {row} (integer?) row to inspect, 0-based. Defaults to the row of the current cursor
- {col} (integer?) col to inspect, 0-based. Defaults to the col of the current cursor
- {filter} (table?) A table with the following fields:
  - {extmarks} (boolean|"all", default: true) Include extmarks. When all, then extmarks without a hl_group will also be included.
  - {semantic_tokens} (boolean, default: true) Include semantic token highlights.
  - {syntax} (boolean, default: true) Include syntax based highlight groups.
  - {treesitter} (boolean, default: true) Include treesitter based highlight groups.

Lua module: vim.base64 vim.base64

vim.base64.decode({str}) vim.base64.decode()
Decode a Base64 encoded string.

Parameters:
- {str} (string) Base64 encoded string

Return:
(string) Decoded string

vim.base64.encode({str}) vim.base64.encode()
Encode {str} using Base64.

Parameters:
- {str} (string) String to encode

Return:
(string) Encoded string

Lua module: vim.filetype vim.filetype

vim.filetype.add({filetypes}) vim.filetype.add()
Add new filetype mappings.

Filetype mappings can be added either by extension or by filename (either the "tail" or the full file path). The full file path is checked first, followed by the file name. If a match is not found using the filename, then the filename is matched against the list of lua-patterns (sorted by priority) until a match is found. Lastly, if pattern matching does not find a filetype, then the file extension is used. Extension mappings match only the text after the final dot in the filename.

The filetype can be either a string (in which case it is used as the filetype directly) or a function. If a function, it takes the full path and buffer number of the file as arguments (along with captures from the matched pattern, if any) and should return a string that will be used as the buffer's filetype. Optionally, the function can return a second function value which, when called, modifies the state of the buffer. This can be used to, for example, set filetype-specific buffer variables. This function will be called by Nvim before setting the buffer's filetype.

Filename patterns can specify an optional priority to resolve cases when a file path matches multiple patterns. Higher priorities are matched first. When omitted, the priority defaults to 0. A pattern can contain environment variables of the form "${SOME_VAR}" that will be automatically expanded. If the environment variable is not set, the pattern won't be matched.

See $VIMRUNTIME/lua/vim/filetype.lua for more examples.

Example:

```
vim.filetype.add({
  extension = {
    foo = 'fooscript',
    bar = function(path, bufnr)
      if some_condition() then
        return 'barscript', function(bufnr)
          -- Set a buffer variable
          vim.b[bufnr].barscript_version = 2
        end
      end
      return 'bar'
    end,
  },
  filename = {
    ['.foorc'] = 'toml',
    ['/etc/foo/config'] = 'toml',
  },
  pattern = {
    ['.*/etc/foo/.*'] = 'fooscript',
    -- Using an optional priority
    ['.*/etc/foo/.*%.conf'] = { 'dosini', { priority = 10 } },
    -- A pattern containing an environment variable
    ['${XDG_CONFIG_HOME}/foo/git'] = 'git',
    ['.*README.(%a+)'] = function(path, bufnr, ext)
      if ext == 'md' then
        return 'markdown'
      elseif ext == 'rst' then
        return 'rst'
      end
    end,
  },
})
```

To add a fallback match on contents, use

```
vim.filetype.add {
  pattern = {
    ['.*'] = {
      function(path, bufnr)
        local content = vim.api.nvim_buf_get_lines(bufnr, 0, 1, false)[1] or ''
        if vim.regex([[^#!.*\\<mine\\>]]):match_str(content) ~= nil then
          return 'mine'
        elseif vim.regex([[\\<drawing\\>]]):match_str(content) ~= nil then
          return 'drawing'
        end
      end,
      { priority = -math.huge },
    },
  },
}
```

Parameters:
- {filetypes} (table) A table containing new filetype maps (see example).
  - {extension}? (vim.filetype.mapping)
  - {filename}? (vim.filetype.mapping)
  - {pattern}? (vim.filetype.mapping)

vim.filetype.get_option() vim.filetype.get_option({filetype}, {option}) Get the default option value for a {filetype}.

The returned value is what would be set in a new buffer after 'filetype' is set, meaning it should respect all FileType autocmds and ftplugin files.

Example:

```
vim.filetype.get_option('vim', 'commentstring')
```

Note: this uses nvim_get_option_value() but caches the result. This means ftplugin and FileType autocommands are only triggered once and may not reflect later changes.

Attributes:
Since: 0.9.0

Parameters:
- {filetype} (string) Filetype
- {option} (string) Option name

Return:
(string|boolean|integer) Option value

vim.filetype.inspect() vim.filetype.inspect()
Inspect the current state of the filetype registry.

Returns a copy of the internal tables used for filetype detection by extension, filename, or pattern. **Note:** Due to the dynamic nature of filetype detection, this is only useful for checking whether a certain extension, filename, or pattern has been registered so far. In addition, the pattern table is in an internal format optimized for fast lookup. Prefer vim.filetype.match() for checking the detected filetype for a given pattern.

Return:
({ extension: vim.filetype.mapping, filename: vim.filetype.mapping, pattern: table<string, vim.filetype.mapping> })

vim.filetype.match({args}) vim.filetype.match()
Perform filetype detection.

The filetype can be detected using one of three methods:
1. Using an existing buffer
2. Using only a file name
3. Using only file contents

Of these, option 1 provides the most accurate result as it uses both the buffer's filename and (optionally) the buffer contents. Options 2 and 3 can be used without an existing buffer, but may not always provide a match in cases where the filename (or contents) cannot unambiguously determine the filetype.

Each of the three options is specified using a key to the single argument of this function. Example:

```
-- Using a buffer number
vim.filetype.match({ buf = 42 })

-- Override the filename of the given buffer
vim.filetype.match({ buf = 42, filename = 'foo.c' })

-- Using a filename without a buffer
vim.filetype.match({ filename = 'main.lua' })

-- Using file contents
vim.filetype.match({ contents = {'#!/usr/bin/env bash'} })
```

Parameters:
- {args} (table) Table specifying which matching strategy to use. Accepted keys are:
  - {buf}? (integer) Buffer number to use for matching. Mutually exclusive with {contents}
  - {contents}? (string[]) An array of lines representing file contents to use for matching. Can be used with {filename}. Mutually exclusive with {buf}.
  - {filename}? (string) Filename to use for matching. When {buf} is given, defaults to the filename of the given buffer number. The file need not actually exist in the filesystem. When used without {buf} only the name of the file is used for filetype matching. This may

result in failure to detect the filetype in cases where the filename alone is not enough to disambiguate the filetype.

Return (multiple):
(`string?`) The matched filetype, if any. (`function?`) A function `fun(buf: integer)` that modifies buffer state when called (for example, to set some filetype specific buffer variables). (`boolean?`) true if a match was found by falling back to a generic filetype (i.e., ".conf"), which indicates the filetype should be set with `:setf FALLBACK conf`. See :setfiletype.

Lua module: vim.fs

vim.fs

vim.fs.copy()

Use filecopy() or uv.fs_copyfile() to performantly copy an existing file.

Example:

```
vim.fn.filecopy('foo.txt', 'bar.txt')
```

vim.fs.exists()

Use uv.fs_stat() to check a file's type, and whether it exists.

Example:

```
if vim.uv.fs_stat(file) then
  vim.print('file exists')
end
```

vim.fs.read()

You can use readblob() to get a file's contents without explicitly opening/closing it. Or use io.lines() to iterate lines in a text file.

Example:

```
vim.print(vim.fn.readblob('.git/config'))
```

vim.fs.write()

You can use writefile() to write a file without explicitly opening/closing it.

Example:

```
vim.fn.writefile('foo\0bar', 'data.bin', 'b')
```

vim.fs.abspath({path}, {opts}) vim.fs.abspath()
Converts path to an absolute path. Expands tilde (~) at the beginning of the path (unless plain=true). Does not check if the path exists, normalize the path, resolve symlinks or hardlinks (including "." and ".."), or expand environment variables. If the path is already absolute, it is returned unchanged. Converts \ path separators to /.

Attributes:
Since: 0.11.0

Parameters:
- {path} (`string`) Path
- {opts} (`table?`) A table with the following fields:
  - {cwd}? (`string`) Resolve the path relative to this directory.
  - {plain}? (`boolean`) Do not expand tilde (~).

Return:
(`string`) Absolute path

vim.fs.basename({file}) vim.fs.basename()
Gets the basename of the given path (not expanded/resolved).

Attributes:
Since: 0.8.0

Parameters:
- {file} (`string?`) Path

Return:
(`string?`) Basename of `file`

vim.fs.dir({path}, {opts}) vim.fs.dir()
Gets an iterator over items found in path (normalized via vim.fs.normalize()).

Example:

```
for name, type, err in vim.fs.dir(path, { err = true }) do
  if err then
    -- Failed to scan directory {name} (may be the root {path} itself).
  end
end
```

Attributes:
Since: 0.8.0

Parameters:
- {path} (`string`) Directory to iterate over, expanded (unless `opts.plain=true`) and normalized.
- {opts} (`table?`) A table with the following fields:
  - {depth}? (`integer`, default: 1) How deep to traverse.

- {err}? (boolean, default: false) Report errors via the iterator's third value ("err"), instead of silently skipping.
- {follow}? (boolean, default: false) Follow symbolic links.
- {plain}? (boolean, default: false) Do not expand special forms like "~" and "$" in {path}.
- {skip}? (fun(dir_name: string): boolean) Predicate to control traversal. Return false to stop searching the current directory. Only useful when depth > 1 Return an iterator over the items located in {path}

Return:
(fun(): string?, string?, string?) Iterator over items in {path}, yielding (name, type, err):
- name: Basename of the item relative to {path}.
- type: One of: "file", "directory", "link", "fifo", "socket", "char", "block", "unknown".
- err: Error string, or nil. Only if opts.err=true. If the root {path} itself could not be scanned, yields a single (name, nil, err) item.

vim.fs.dirname({file}) vim.fs.dirname()
Gets the parent directory of the given path (not expanded/resolved, the caller must do that).

Attributes:
Since: 0.8.0

Parameters:
- {file} (string?) Path

Return:
(string?) Parent directory of file

vim.fs.ext({file}, {opts}) vim.fs.ext()
Return the file's last extension, if any.

Similar to fnamemodify() with the ::e modifier. The extension does not include a leading period.

Examples:

```
vim.fs.ext('archive.tar.gz') -- 'gz'
vim.fs.ext('~/.git') -- ''
vim.fs.ext('plugin/myplug.lua') -- 'lua'
```

Attributes:
Since: 0.12.0

Parameters:
- {file} (string) Path
- {opts} (table?) Reserved for future use

Return:
(string) Extension of {file}

vim.fs.find({names}, {opts}) vim.fs.find()
Find files or directories (or other items as specified by opts.type) in the given path.

Finds items given in {names} starting from {path}. If {upward} is "true" then the search traverses upward through parent directories; otherwise, the search traverses downward. Note that downward searches are recursive and may search through many directories! If {stop} is non-nil, then the search stops when the directory given in {stop} is reached. The search terminates when {limit} (default 1) matches are found. You can set {type} to "file", "directory", "link", "socket", "char", "block", or "fifo" to narrow the search to find only that type.

Examples:

```
-- List all test directories under the runtime directory.
local dirs = vim.fs.find(
  { 'test', 'tst', 'testdir' },
  { limit = math.huge, type = 'directory', path = './runtime/' }
)

-- Get all "lib/*.cpp" and "lib/*.hpp" files, using Lua patterns.
-- Or use `vim.glob.to_lpeg(…):match(…)` for glob/wildcard matching.
local files = vim.fs.find(function(name, path)
  return name:match('.*%.[ch]pp$') and path:match('[/\\]lib$')
end, { limit = math.huge, type = 'file' })
```

Attributes:
Since: 0.8.0

Parameters:
- {names} (string|string[]|fun(name: string, path: string): boolean) Names of the items to find. Must be base names, paths and globs are not supported when {names} is a string or a table. If {names} is a function, it is called for each traversed item with args:
  - name: base name of the current item
  - path: full path of the directory containing the current item

The function should return true if the given item is considered a match.
- {opts} (table?) Optional keyword arguments:
  - {follow}? (boolean, default: false) Follow symbolic links.
  - {limit}? (number, default: 1) Stop searching after this many matches. Use math.huge for "unlimited".
  - {path}? (string) Path to begin searching from, defaults to current-directory. Not expanded.
  - {stop}? (string) Stop searching when this directory is reached. The directory itself is not searched.
  - {type}? (string) Find only items of the given type. If omitted, all items that match names are included. With follow, a symlink has the type of its target.
  - {upward}? (boolean, default: false) Search upward through parent directories. Otherwise, search child directories (recursively).

Return (multiple):
(string[]) Normalized paths vim.fs.normalize() of all matching items. (string[]) Errors collected while searching.

vim.fs.joinpath({...}) vim.fs.joinpath()

Concatenates partial paths (one absolute or relative path followed by zero or more relative paths). Slashes are normalized: redundant slashes are removed, and (on Windows) backslashes are replaced with forward-slashes. Empty segments are removed. Paths are not expanded/resolved.

Examples:

- "foo/", "/bar" => "foo/bar"
- "", "after/plugin" => "after/plugin"
- Windows: "a\foo\", "\bar" => "a/foo/bar"

Attributes:
Since: 0.10.0

Parameters:
- `{...}` (`string`)

Return:
(`string`)

vim.fs.mkdir({path}, {opts}) vim.fs.mkdir()

Creates a directory.

Attributes:
Since: 0.13.0

Parameters:
- `{path}` (`string`) Path to create (not expanded/resolved).
- `{opts}` (`table?`) Optional keyword arguments.
  - `{mode}?` (`integer`, default: 493) Permission bits for newly-created directories.
  - `{parents}?` (`boolean`, default: `false`) Create intermediate directories as necessary.

vim.fs.normalize({path}, {opts}) vim.fs.normalize()

Normalize a path to a standard format. Expands environment variables, and tilde "~" at the beginning of the path. Resolves "." and ".." components, except when the path is relative and resolving it would produce an absolute path.

- "." as the only part in a relative path:
  - "." => "."
  - "./." => "."
- ".." when it leads outside the current directory
  - "foo/../../bar" => "../bar"
  - "../../foo" => "../../foo"
- ".." in the root directory returns the root directory.
  - "/../../" => "/"

On Windows, backslashes (`\`) are converted to forward slashes (`/`).

Examples:

```
[[C:\Users\jdoe]]                         --> "C:/Users/jdoe"
"~/src/neovim"                            --> "/home/jdoe/src/neovim"
"$XDG_CONFIG_HOME/nvim/init.vim"          --> "/Users/jdoe/.config/nvim/init.vim"
"~/src/nvim/api/../tui/./tui.c"           --> "/home/jdoe/src/nvim/tui/tui.c"
"./foo/bar"                               --> "foo/bar"
"foo/../../../bar"                        --> "../../bar"
"/home/jdoe/../../../bar"                 --> "/bar"
"C:foo/../../baz"                         --> "C:../baz"
"C:/foo/../../baz"                        --> "C:/baz"
[[\\?\UNC\server\share\foo\..\..\..\bar]] --> "//?/UNC/server/share/bar"
```

Attributes:
Since: 0.8.0

Parameters:
- `{path}` (`string`) Path to normalize
- `{opts}` (`table?`) A table with the following fields:
  - `{plain}?` (`boolean`, default: `false`) Do not expand environment variables and leading tildes "~".
  - `{win}?` (`boolean`, default: `true` in Windows, `false` otherwise) Path is a Windows path.

Return:
(`string`) Normalized path

vim.fs.parents({start}) vim.fs.parents()

Iterate over all the parents of the given path (not expanded/resolved, the caller must do that).

Example:

```
local root_dir
for dir in vim.fs.parents(vim.api.nvim_buf_get_name(0)) do
  if vim.fn.isdirectory(dir .. '/.git') == 1 then
    root_dir = dir
    break
  end
end

if root_dir then
  print('Found git repository at', root_dir)
end
```

Attributes:

Since: 0.8.0

Parameters:
- {start} (string) Initial path.

Return (multiple):
(fun(_, dir: string): string?) Iterator (nil) (string?)

vim.fs.relpath({base}, {target}, {opts}) vim.fs.relpath()
Gets target path relative to base, or nil if base is not an ancestor.

Example:

```
vim.fs.relpath('/var', '/var/lib') -- 'lib'
vim.fs.relpath('/var', '/usr/bin') -- nil
```

Attributes:
Since: 0.11.0

Parameters:
- {base} (string)
- {target} (string)
- {opts} (table?) Reserved for future use

Return:
(string?)

vim.fs.rm({path}, {opts}) vim.fs.rm()
Removes a file or directory.

Removes symlinks without touching the origin. To remove the origin, resolve it explicitly with uv.fs_realpath():

```
vim.fs.rm(vim.uv.fs_realpath('symlink-dir'), { recursive = true })
```

Attributes:
Since: 0.11.0

Parameters:
- {path} (string) Path to remove (not expanded/resolved).
- {opts} (table?) A table with the following fields:
  - {force}? (boolean) Ignore nonexistent files and arguments.
  - {recursive}? (boolean) Remove directory contents recursively.

vim.fs.root({source}, {marker}) vim.fs.root()
Find the first parent directory containing a specific "marker", relative to a file path or buffer.

If the buffer is unnamed (has no backing file) or has a non-empty 'buftype' then the search begins from Nvim's current-directory.

Examples:

```
-- Find the root of a Python project, starting from file 'main.py'
vim.fs.root(vim.fs.joinpath(vim.env.PWD, 'main.py'), {'pyproject.toml', 'setup.py' })

-- Find the root of a git repository
vim.fs.root(0, '.git')

-- Find the parent directory containing any file with a .csproj extension
vim.fs.root(0, function(name, path)
  return vim.fs.ext(name) == 'csproj'
end)

-- Find the first ancestor directory containing EITHER "stylua.toml" or ".luarc.json"; if
-- not found, find the first ancestor containing ".git":
vim.fs.root(0, { { 'stylua.toml', '.luarc.json' }, '.git' })
```

Attributes:
Since: 0.10.0

Parameters:
- {source} (integer|string) Buffer number (0 for current buffer) or file path (absolute or relative, expanded via abspath()) to begin the search from.
- {marker} ((string|string[]|fun(name: string, path: string): boolean)[]|string|fun(name: string, path: string): boolean) Filename, function, or list thereof, that decides how to find the root. To indicate "equal priority", specify items in a nested list { { 'a.txt', 'b.lua' }, … }. A function item must return true if name and path are a match. Each item (which may itself be a nested list) is evaluated in-order against all ancestors, until a match is found.

Return:
(string?) Directory path containing one of the given markers, or nil if no directory was found.

vim.fs.slug({path}, {opts}) vim.fs.slug()
Gets a filesystem-safe, mnemonic slug (readable prefix + short hash) of an arbitrary filepath or other "identity string".
- The input is normalized so equivalent paths produce the same result.
- A hash of the normalized input is appended to prevent collisions.
- Unsafe chars are replaced with "-".
- $HOME is replaced with "~".
- URIs (scheme://...) are prefixed with "=uri-{scheme}-".
- UNC paths (Windows) are prefixed with "=unc-".
- If opts.maxlen is exceeded, the result will be truncated to {head}~~~{tail}-{hash8}.
- If the sanitized name is empty, the reserved label =special will be used.

Examples:

```
vim.print(vim.fs.slug('/tmp/test/foo.md'))           --> "tmp-test-foo.md-{hash}"
vim.print(vim.fs.slug('C:/src/project/main.c'))      --> "C--src-project-main.c-{hash}"
vim.print(vim.fs.slug(vim.fn.expand('~/file.txt')))  --> "~-file.txt-{hash}"
vim.print(vim.fs.slug('---'))                        --> "=special-{hash}"
vim.print(vim.fs.slug('term://foo/bar//123:bash'))   --> "=uri-term-foo-bar-123-bash-{hash}"
vim.print(vim.fs.slug(('/a/very/long/path'):rep(10) .. '/file.txt', { maxlen = 60 }))
   --> "a-very-long-~~~-path-a-very-long-path-file.txt-{hash}"
```

Attributes:
Since: 0.13.0

Parameters:
- {path} (string) Filepath (or other identity string).
- {opts} ({ maxlen?: integer }?)
  - maxlen: (integer, default: 180) Max length (bytes) of the result.

Return:
(string) Filesystem-safe, mnemonic slug.

Lua module: vim.glob

vim.glob

Glob-to-LPeg Converter (Peglob) This module converts glob patterns to LPeg patterns according to the LSP 3.17 specification: https://microsoft.github.io/language-server-protocol/specifications/lsp/3.17/specification/#pattern

Glob grammar overview:
- * to match zero or more characters in a path segment
- ? to match on one character in a path segment
- ** to match any number of path segments, including none
- {} to group conditions (e.g. *.{ts,js} matches TypeScript and JavaScript files)
- [] to declare a range of characters to match in a path segment (e.g., example.[0-9] to match on example.0, example.1, …)
- [!...] to negate a range of characters to match in a path segment (e.g., example.[!0-9] to match on example.a, example.b, but not example.0)

Additional constraints:
- A Glob pattern must match an entire path, with partial matches considered failures.
- The pattern only determines success or failure, without specifying which parts correspond to which characters.
- A path segment is the portion of a path between two adjacent path separators (/), or between the start/end of the path and the nearest separator.
- The ** (globstar) pattern matches zero or more path segments, including intervening separators (/). Within pattern strings, ** must be delimited by path separators (/) or pattern boundaries and cannot be adjacent to any characters other than /. If ** is not the final element, it must be followed by /.
- {} (braced conditions) contains valid Glob patterns as branches, separated by commas. Commas are exclusively used for separating branches and cannot appear within a branch for any other purpose. Nested {} structures are allowed, but {} must contain at least two branches—zero or one branch is not permitted.
- In [] or [!...], a character range consists of character intervals (e.g., a-z) or individual characters (e.g., w). A range including / won't match that character.

vim.glob.to_lpeg({pattern}) vim.glob.to_lpeg()
Parses a raw glob into an lua-lpeg pattern.

Parameters:
- {pattern} (string) The raw glob pattern

Return:
(vim.lpeg.Pattern) An lua-lpeg representation of the pattern

Lua module: vim.hl

vim.hl

vim.hl.hl_op({opts}) vim.hl.hl_op()
Highlights the affected text region during a TextYankPost or TextPutPost event.

Add this to your init.vim:

```
autocmd TextYankPost * silent! lua vim.hl.hl_op {higroup='Visual', timeout=300}
autocmd TextPutPost  * silent! lua vim.hl.hl_op {higroup='Visual', timeout=300}
```

Parameters:
- {opts} (table?) Optional parameters
  - event (default: vim.v.event) Event structure.
  - higroup (default: "IncSearch") Highlight group for the text region.
  - on_macro (default: false) Highlight during macro execution.
  - on_visual (default: true) Highlight during Visual mode.
  - priority (default: vim.hl.priorities.user) Integer priority.
  - timeout (default: 150) Time in ms before highlight is cleared.

vim.hl.priorities vim.hl.priorities
Table with default priorities used for highlighting:
- syntax: 50, used for standard syntax highlighting
- treesitter: 100, used for treesitter-based highlighting
- semantic_tokens: 125, used for LSP semantic token highlighting
- diagnostics: 150, used for code analysis such as diagnostics

- `user`: 200, used for user-triggered highlights such as LSP document symbols or `hl_op` autocommands

vim.hl.range()

vim.hl.range({buf}, {ns}, {hlgroup}, {start}, {finish}, {opts}) Apply highlight group to range of text.

Parameters:
- {buf} (integer) Buffer number to apply highlighting to
- {ns} (integer) Namespace to add highlight to
- {hlgroup} (integer|integer[]|string|string[]) Highlight group used for the text range. See the `hl_group` option in nvim_buf_set_extmark().
- {start} ([integer,integer]|string) Start of region as a (line, column) tuple or string accepted by getpos()
- {finish} ([integer,integer]|string) End of region as a (line, column) tuple or string accepted by getpos()
- {opts} (table?) A table with the following fields:
  - {inclusive}? (boolean, default: false) Indicates whether the range is end-inclusive
  - {priority}? (integer, default: vim.hl.priorities.user) Highlight priority
  - {regtype}? (string, default: 'v' i.e. charwise) Type of range. See getregtype()
  - {timeout}? (integer, default: -1 no timeout) Time in ms before highlight is cleared

Return (multiple):
(uv.uv_timer_t?) range_timer A timer which manages how much time the highlight has left (fun()?) range_clear A function which allows clearing the highlight manually. nil is returned if timeout is not specified

Lua module: vim.iter

vim.iter

vim.iter() is an interface for iterables: it wraps a table or function argument into an Iter object with methods (such as Iter:filter() and Iter:map()) that transform the underlying source data. These methods can be chained to create iterator "pipelines": the output of each pipeline stage is input to the next stage. The first stage depends on the type passed to `vim.iter()`:
- Lists or arrays (lua-list) yield only the value of each element.
  - Holes (nil values) are allowed (but discarded).
  - Use pairs() to treat array/list tables as dicts (preserve holes and non-contiguous integer keys): `vim.iter(pairs(…))`.
  - Use Iter:enumerate() to also pass the index to the next stage.
    - Or initialize with ipairs(): `vim.iter(ipairs(…))`.
- Non-list tables (lua-dict) yield both the key and value of each element.
- Function iterators yield all values returned by the underlying function.
- Tables with a __call() metamethod are treated as function iterators.

The iterator pipeline terminates when the underlying iterable is exhausted (for function iterators this means it returned nil).

Note: `vim.iter()` scans table input to decide if it is a list or a dict; to avoid this cost you can wrap the table with an iterator e.g. `vim.iter(ipairs({…}))`, but that precludes the use of list-iterator operations such as IterArray:rev()).

Examples:

```
local it = vim.iter({ 1, 2, 3, 4, 5 })
it:map(function(v)
  return v * 3
end)
it:rev()
it:skip(2)
it:totable()
-- { 9, 6, 3 }

-- ipairs() is a function iterator which returns both the index (i) and the value (v)
vim.iter(ipairs({ 1, 2, 3, 4, 5 })):map(function(i, v)
  if i > 2 then return v end
end):totable()
-- { 3, 4, 5 }

local it = vim.iter(vim.gsplit('1,2,3,4,5', ','))
it:map(function(s) return tonumber(s) end)
for i, d in it:enumerate() do
  print(string.format("Column %d is %d", i, d))
end
-- Column 1 is 1
-- Column 2 is 2
-- Column 3 is 3
-- Column 4 is 4
-- Column 5 is 5

vim.iter({ a = 1, b = 2, c = 3, z = 26 }):any(function(k, v)
  return k == 'z'
end)
-- true

local rb = vim.ringbuf(3)
rb:push("a")
rb:push("b")
vim.iter(rb):totable()
-- { "a", "b" }
```

Iter:all({pred}) Iter:all()
Returns true if all items in the iterator match the given predicate.

Attributes:
Since: 0.10.0

Parameters:
- `{pred}` (`fun(v: V1, ...: V...): boolean`) Predicate function. Takes all values returned from the previous stage in the pipeline as arguments and returns true if the predicate matches.

Iter:any(`{pred}`) Iter:any()
Returns true if any of the items in the iterator match the given predicate.

Attributes:
Since: 0.10.0

Parameters:
- `{pred}` (`fun(v: V1, ...: V...): boolean`) Predicate function. Takes all values returned from the previous stage in the pipeline as arguments and returns true if the predicate matches.

Iter:count() Iter:count()
Drains the iterator, counting the number of iterations and returning it.

Attributes:
Since: 0.13.0

Return:
(`integer`)

Iter:each(`{f}`) Iter:each()
Calls a function once for each item in the pipeline, draining the iterator.

For functions with side effects. To modify the values in the iterator, use Iter:map().

Attributes:
Since: 0.10.0

Parameters:
- `{f}` (`fun(v: V1, ...: V...)`) Function to execute for each item in the pipeline. Takes all of the values returned by the previous stage in the pipeline as arguments.

Iter:enumerate() Iter:enumerate()
Yields the item index (count) and value for each item of an iterator pipeline.

For list tables, this is more efficient:

```
vim.iter(ipairs(t))
```

instead of:

```
vim.iter(t):enumerate()
```

Example:

```
local it = vim.iter(vim.gsplit('abc', '')):enumerate()
it:next()
-- 1    'a'
it:next()
-- 2    'b'
it:next()
-- 3    'c'
```

Attributes:
Since: 0.10.0

Overloads:
- `fun<V1, V...>(self: vim.IterArray<V1, V...>): vim.IterArray<integer, V1, V...>`

Return:
(`vim.Iter<integer, V1, V...>`)

Iter:filter(`{f}`) Iter:filter()
Filters an iterator pipeline.

Example:

```
local bufs = vim.iter(vim.api.nvim_list_bufs()):filter(vim.api.nvim_buf_is_loaded)
```

Parameters:
- `{f}` (`fun(v: V1, ...: V...): boolean`) Takes all values returned from the previous stage in the pipeline and returns false or nil if the current iterator element should be removed.

Overloads:
- `fun<V1, V...>(self: vim.IterArray<V1, V...>, f: fun(v: V1, ...: V...): boolean): vim.IterArray<V1, V...>`

Return:
(`vim.Iter<V1, V...>`)

Iter:find(`{f}`) Iter:find()
Find the first value in the iterator that satisfies the given predicate.

Advances the iterator. Returns nil and drains the iterator if no value is found.

Examples:

```
local it = vim.iter({ 3, 6, 9, 12 })
it:find(12)
-- 12

local it = vim.iter({ 3, 6, 9, 12 })
it:find(20)
-- nil

local it = vim.iter({ 3, 6, 9, 12 })
it:find(function(v) return v % 4 == 0 end)
-- 12
```

Attributes:
Since: 0.10.0

Parameters:
- `{f}` (`V1|fun(v: V1, ...: V...): any`)

Return (multiple):
(`V1?`) (`V...`)

Iter:fold(`{init}`, `{f}`) Iter:fold()
Folds ("reduces") an iterator into a single value. Iter:reduce()

Examples:

```
-- Create a new table with only even values
vim.iter({ a = 1, b = 2, c = 3, d = 4 })
  :filter(function(k, v) return v % 2 == 0 end)
  :fold({}, function(acc, k, v)
    acc[k] = v
    return acc
  end) --> { b = 2, d = 4 }

-- Get the "maximum" item of an iterable.
vim.iter({ -99, -4, 3, 42, 0, 0, 7 })
  :fold({}, function(acc, v)
    acc.max = math.max(v, acc.max or v)
    return acc
  end) --> { max = 42 }
```

Attributes:
Since: 0.10.0

Parameters:
- `{init}` (any) Initial value of the accumulator.
- `{f}` (`fun(acc: A, v: V1, ...: V...): A`) Accumulation function.

Return:
(any)

Iter:join(`{delim}`) Iter:join()
Collect the iterator into a delimited string.

Each element in the iterator is joined into a string separated by `{delim}`.

Consumes the iterator.

Attributes:
Since: 0.10.0

Parameters:
- `{delim}` (`string`) Delimiter

Return:
(`string`)

Iter:last() Iter:last()
Drains the iterator and returns the last item.

Example:

```
local it = vim.iter(vim.gsplit('abcdefg', ''))
it:last()
-- 'g'

local it = vim.iter({ 3, 6, 9, 12, 15 })
it:last()
-- 15
```

Attributes:
Since: 0.10.0

Return (multiple):
(`V1?`) (`V...`)

See also:
- IterArray:rpeek()

Iter:map({f}) Iter:map()
Maps the items of an iterator pipeline to the values returned by `f`.

If the map function returns nil, the value is filtered from the iterator.

Example:

```
local it = vim.iter({ 1, 2, 3, 4 }):map(function(v)
  if v % 2 == 0 then
    return v * 3
  end
end)
it:totable()
-- { 6, 12 }
```

Attributes:
Since: 0.10.0

Parameters:
- `{f}` (`fun(v: V1, ...: V...): K2, V2...`) Mapping function. Takes all values returned from the previous stage in the pipeline as arguments and returns one or more new values, which are used in the next pipeline stage. Nil return values are filtered from the output.

Overloads:
- `fun<V1, V..., K1, K...>(self: vim.IterArray<V1, V...>, f: fun(v: V1, ...: V...): K1, K...): vim.IterArray<K1, K...>`

Return:
(`vim.Iter<K2, V2...>`)

Iter:next() Iter:next()
Gets the next value from the iterator.

Example:

```
local it = vim.iter(string.gmatch('1 2 3', '%d+')):map(tonumber)
it:next()
-- 1
it:next()
-- 2
it:next()
-- 3
```

Attributes:
Since: 0.10.0

Return (multiple):
(`V1?`) (`V...`)

Iter:nth({n}) Iter:nth()
Gets the nth value of an iterator (and advances to it).

If n is negative, offsets from the end of a list-iterator.

Example:

```
local it = vim.iter({ 3, 6, 9, 12 })
it:nth(2)
-- 6
it:nth(2)
-- 12

local it2 = vim.iter({ 3, 6, 9, 12 })
it2:nth(-2)
-- 9
it2:nth(-2)
-- 3
```

Attributes:
Since: 0.10.0

Parameters:
- `{n}` (`integer`) Index of the value to return. May be negative if the source is a list-iterator.

Return (multiple):
(`V1?`) (`V...`)

Iter:peek() Iter:peek()
Gets the next value from the iterator without consuming it.

The value returned by Iter:peek() will be returned again by the next call to Iter:next().

Example:

```
local it = vim.iter({ 3, 6, 9, 12 })
it:peek()
-- 3
it:peek()
-- 3
it:next()
-- 3
```

Attributes:
Since: 0.10.0

Return (multiple):
(V1?) (`V...`)

Iter:skip({n}) Iter:skip()
Skips n values of an iterator pipeline, or skips values while a predicate returns lua-truthy.

When a predicate is used, skipping stops at the first value for which the predicate returns non-truthy. That value is not consumed and will be returned by the next call to Iter:next()

Example:

```
local it = vim.iter({ 3, 6, 9, 12 }):skip(2)
it:next()
-- 9

local function pred(x) return x < 10 end
local it2 = vim.iter({ 3, 6, 9, 12 }):skip(pred)
it2:next()
-- 12
```

Attributes:
Since: 0.10.0

Parameters:
- `{n}` (`integer|fun(v: V1, ...: V...): boolean`) Number of values to skip or a predicate.

Overloads:
- `fun<V1, V...>(self: vim.IterArray<V1, V...>, n: integer|fun(v: V1, ...: V...): boolean): vim.IterArray<V1, V...>`

Return:
(`vim.Iter<V1, V...>`)

Iter:take({n}) Iter:take()
Transforms an iterator to yield only the first n values, or all values satisfying a predicate.

Example:

```
local it = vim.iter({ 1, 2, 3, 4 }):take(2)
it:next()
-- 1
it:next()
-- 2
it:next()
-- nil

local function pred(x) return x < 2 end
local it2 = vim.iter({ 1, 2, 3, 4 }):take(pred)
it2:next()
-- 1
it2:next()
-- nil
```

Attributes:
Since: 0.10.0

Parameters:
- `{n}` (`integer|fun(v: V1, ...: V...): boolean`) Number of values to take or a predicate.

Overloads:
- `fun<V1, V...>(self: vim.IterArray<V1, V...>, n: integer|fun(v: V1, ...: V...): boolean): vim.IterArray<V1, V...>`

Return:
(`vim.Iter<V1, V...>`)

Iter:totable() Iter:totable()
Collect the iterator into a table.

The resulting table depends on the initial source in the iterator pipeline. Array-like tables and function iterators will be collected into an array-like table. If multiple values are returned from the final stage in the iterator pipeline, each value will be included in a table.

Examples:

```
vim.iter(string.gmatch('100 20 50', '%d+')):map(tonumber):totable()
-- { 100, 20, 50 }

vim.iter({ 1, 2, 3 }):map(function(v) return v, 2 * v end):totable()
-- { { 1, 2 }, { 2, 4 }, { 3, 6 } }

vim.iter({ a = 1, b = 2, c = 3 }):filter(function(k, v) return v % 2 ~= 0 end):totable()
-- { { 'a', 1 }, { 'c', 3 } }
```

The generated table is an array-like table with consecutive, numeric indices. To create a map-like table with arbitrary keys, use Iter:fold().

Attributes:
Since: 0.10.0

Return:
(`any[]`)

Iter:unique({key}) Iter:unique()
Removes duplicate values from an iterator pipeline.

Only the first occurrence of each value is kept.

Accepts an optional key argument, which if provided is called for each value in the iterator to compute a hash key for uniqueness comparison. This is useful for deduplicating table values or complex objects. If key returns `nil` for a value, that value will be considered unique, even if multiple values return `nil`.

If a function-based iterator returns multiple arguments, uniqueness is checked based on the first return value. To change this behavior, specify key.

Examples:

```
vim.iter({ 1, 2, 2, 3, 2 }):unique():totable()
-- { 1, 2, 3 }

vim.iter({ {id=1}, {id=2}, {id=1} })
  :unique(function(x)
    return x.id
  end)
  :totable()
-- { {id=1}, {id=2} }
```

Attributes:
Since: 0.12.0

Parameters:
- {key} (`fun(v: V1, ...: V...): any?`) Optional hash function to determine uniqueness of values.

Overloads:
- `fun<V1, V...>(self: vim.IterArray<V1, V...>, key: fun(v: V1, ...: V...): any?): vim.IterArray<V1, V...>`

Return:
(`vim.Iter<V1, V...>`)

See also:
- vim.list.unique()

IterArray:flatten({depth}) IterArray:flatten()
Flattens a list-iterator, un-nesting nested values up to the given {depth}. Errors if it attempts to flatten a dict-like value.

Examples:

```
vim.iter({ 1, { 2 }, { { 3 } } }):flatten():totable()
-- { 1, 2, { 3 } }

vim.iter({1, { { a = 2 } }, { 3 } }):flatten():totable()
-- { 1, { a = 2 }, 3 }

vim.iter({ 1, { { a = 2 } }, { 3 } }):flatten(math.huge):totable()
-- error: attempt to flatten a dict-like table
```

Attributes:
Since: 0.10.0

Parameters:
- {depth} (`integer?`) Depth to which list-iterator should be flattened (defaults to 1)

Return:
(`vim.IterArray<V1, V...>`)

IterArray:pop() IterArray:pop()
"Pops" a value from a list-iterator (gets the last value and decrements the tail).

Example:

```
local it = vim.iter({1, 2, 3, 4})
it:pop()
-- 4
it:pop()
-- 3
```

Attributes:
Since: 0.10.0

Return (multiple):
(V1?) (`V...`)

IterArray:rev() IterArray:rev()
Reverses a list-iterator pipeline.

Example:

```
local it = vim.iter({ 3, 6, 9, 12 }):rev()
it:totable()
-- { 12, 9, 6, 3 }
```

Attributes:
Since: 0.10.0

Return:
(`vim.IterArray<V1, V...>`)

IterArray:rfind({f}) IterArray:rfind()
Gets the first value satisfying a predicate, from the end of a list-iterator.

Advances the iterator. Returns nil and drains the iterator if no value is found.

Examples:

```
local it = vim.iter({ 1, 2, 3, 2, 1 }):enumerate()
it:rfind(1)
-- 5    1
it:rfind(1)
-- 1    1
```

Attributes:
Since: 0.10.0

Parameters:
- `{f}` (`V1|fun(v: V1, ...: V...): boolean`)

Return (multiple):
(`V1?`) (`V...`)

See also:
- Iter:find()

IterArray:rpeek() IterArray:rpeek()
Gets the last value of a list-iterator without consuming it.

Example:

```
local it = vim.iter({1, 2, 3, 4})
it:rpeek()
-- 4
it:rpeek()
-- 4
it:pop()
-- 4
```

Attributes:
Since: 0.10.0

Return (multiple):
(`V1?`) (`V...`)

See also:
- Iter:last()

IterArray:rskip({n}) IterArray:rskip()
Discards n values from the end of a list-iterator pipeline.

Example:

```
local it = vim.iter({ 1, 2, 3, 4, 5 }):rskip(2)
it:next()
-- 1
it:pop()
-- 3
```

Attributes:
Since: 0.10.0

Parameters:
- `{n}` (`integer`)

Return:
(`vim.IterArray<V1, V...>`)

IterArray:slice({`first`}, {`last`}) IterArray:slice()
Sets the start and end of a list-iterator pipeline.

Equivalent to `:skip(first - 1):rskip(len - last + 1)`.

Attributes:
Since: 0.10.0

Parameters:
- `{first}` (`integer`)
- `{last}` (`integer`)

Return:
(`vim.IterArray<V1, V...>`)

Lua module: vim.json vim.json

This module provides encoding and decoding of Lua objects to and from JSON-encoded strings. Supports vim.NIL and vim.empty_dict().

vim.json.decode({str}, {opts}) vim.json.decode()
Decodes (or "unpacks") stringified JSON to a Lua object.
- Decodes JSON "null" as vim.NIL (controllable by {opts}, see below).
- Decodes empty object as vim.empty_dict().
- Decodes empty array as {} (empty Lua table).

Example:

```
vim.print(vim.json.decode('{"bar":[],"foo":{},"zub":null}'))
-- { bar = {}, foo = vim.empty_dict(), zub = vim.NIL }
```

Parameters:
- {str} (string) Stringified JSON data.
- {opts} (table?) A table with the following fields:
  - {luanil}? ({ object?: boolean, array?: boolean }, default: nil) Convert JSON "null" in objects/arrays to Lua nil instead of vim.NIL.
  - {skip_comments}? (boolean, default: false) Allows JavaScript-style comments within JSON data. Comments are treated as whitespace and may appear anywhere whitespace is valid in JSON. Supports single-line comments beginning with '//' and block comments enclosed with '/' and '/'.

Return:
(any)

vim.json.encode({obj}, {opts}) vim.json.encode()
Encodes (or "packs") a Lua object to stringified JSON.

Example: Implement a basic 'formatexpr' for JSON, so gq with a motion formats JSON in a buffer. (The motion must operate on a valid JSON object.)

```
function _G.fmt_json()
  local indent = vim.bo.expandtab and (' '):rep(vim.o.shiftwidth) or '\t'
  local lines = vim.api.nvim_buf_get_lines(0, vim.v.lnum - 1, vim.v.lnum + vim.v.count - 1, true)
  local o = vim.json.decode(table.concat(lines, '\n'))
  local stringified = vim.json.encode(o, { indent = indent, sort_keys = true })
  lines = vim.split(stringified, '\n')
  vim.api.nvim_buf_set_lines(0, vim.v.lnum - 1, vim.v.count, true, lines)
end
vim.o.formatexpr = 'v:lua.fmt_json()'
```

Parameters:
- {obj} (any)
- {opts} (table?) A table with the following fields:
  - {escape_slash}? (boolean, default: false) Escape slash characters "/" in string values.
  - {indent}? (string, default: "") If non-empty, each value in a JSON object or array starts on a new line and is prefixed with indent per nesting level. Adds a space after colons. Does not add a final newline.
  - {sort_keys}? (boolean, default: false) Sort object keys in alphabetical order.

Return:
(string)

Lua module: vim.keymap vim.keymap

vim.keymap.del({modes}, {lhs}, {opts}) vim.keymap.del()
Removes a mapping, or removes each (mode, lhs) pair if lhs is a list.

Examples:

```
vim.keymap.del('n', 'lhs')
vim.keymap.del({'n', 'i', 'v'}, '<leader>w', { buf = 5 })
```

Parameters:
- {modes} (string|string[])
- {lhs} (string|string[])
- {opts} (table?) A table with the following fields:
  - {buf}? (integer) Remove a mapping from the given buffer. 0 for current.
  - {lhs}? (boolean) When true, only match {lhs}, not {rhs}.

See also:
- vim.keymap.set()

vim.keymap.set({modes}, {lhs}, {rhs}, {opts}) vim.keymap.set()
Defines a mapping of keycodes to a function or keycodes. If lhs is a list, defines a mapping for each (mode, lhs) pair.

Examples:

```
-- Map "x" to a Lua function:
vim.keymap.set('n', 'x', function() print('real lua function') end)
-- Map "<leader>x" to multiple modes for the current buffer:
vim.keymap.set({'n', 'v'}, '<leader>x', vim.lsp.buf.references, { buf = 0 })
-- Map <Tab> to an expression (|:map-<expr>|):
vim.keymap.set('i', '<Tab>', function()
  return vim.fn.pumvisible() == 1 and '<C-n>' or '<Tab>'
end, { expr = true })
-- Map "[%%" to a <Plug> mapping:
vim.keymap.set('n', '[%%', '<Plug>(MatchitNormalMultiBackward)')

-- Use `getregionpos(getpos('v'))` to get the "current visual selection":
vim.keymap.set('x', 'M', function()
  local region = vim.fn.getregionpos(vim.fn.getpos('v'), vim.fn.getpos('.'), {
    type = 'v',
    exclusive = false,
    eol = false,
    bounds = true,
  })
  local line1 = region[1][1][2]
  local line2 = region[1][2][2]
  vim.print({ line1, line2 })
end)

vim.keymap.set({ 'n', 'i' }, { 'a', 'b' }, '<cmd>echom localtime()<cr>')
-- ... is the same as:
vim.keymap.set('n', 'a', '<cmd>echom localtime()<cr>')
vim.keymap.set('i', 'a', '<cmd>echom localtime()<cr>')
vim.keymap.set('n', 'b', '<cmd>echom localtime()<cr>')
vim.keymap.set('i', 'b', '<cmd>echom localtime()<cr>')
```

Parameters:
- {modes} (`string|string[]`) Mode "short-name" (see nvim_set_keymap()), or a list thereof.
- {lhs} (`string|string[]`) Left-hand side {lhs} of the mapping, or a list thereof.
- {rhs} (`string|function`) Right-hand side {rhs} of the mapping, can be a Lua function.
- {opts} (`table?`) Table of :map-arguments. Same as nvim_set_keymap() {opts}, except:
  - {replace_keycodes} defaults to `true` if "expr" is `true`.
  - {noremap} is not supported; use {remap} instead (see below).

Also accepts:
- {buf}? (`integer`) Creates buffer-local mapping, `0` for current buffer.
- {remap}? (`boolean`, default: `false`) Make the mapping recursive. Inverse of {noremap}.

See also:
- nvim_set_keymap()
- maparg()
- mapcheck()
- mapset()

Lua module: vim.loader

vim.loader

vim.loader.enable({enable}) vim.loader.enable()

WARNING: This feature is experimental/unstable.

Enables or disables the experimental Lua module loader:

Enable (`enable=true`):
- overrides loadfile()
- adds the Lua loader using the byte-compilation cache
- adds the libs loader
- removes the default Nvim loader

Disable (`enable=false`):
- removes the loaders
- adds the default Nvim loader

Parameters:
- {enable} (`boolean?`) true/nil to enable, false to disable

vim.loader.find({modname}, {opts}) vim.loader.find()

WARNING: This feature is experimental/unstable.

Finds Lua modules for the given module name.

Parameters:
- {modname} (`string`) Module name, or `"*"` to find the top-level modules instead
- {opts} (`table?`) Options for finding a module:
  - {all}? (`boolean`, default: `false`) Search for all matches.
  - {paths}? (`string[]`, default: {}) Extra paths to search for modname
  - {patterns}? (`string[]`, default: `{"/init.lua", ".lua"}`) List of patterns to use when searching for modules. A pattern is a string added to the basename of the Lua module being searched.
  - {rtp}? (`boolean`, default: `true`) Search for modname in the runtime path.

Return:
(`table[]`) A list of objects with the following fields:
- {modname} (`string`) Name of the module

- {modpath} (string) Path of the module
- {stat}? (uv.fs_stat.result) The fs_stat of the module path. Won't be returned for modname="*"

vim.loader.reset({path}) vim.loader.reset()
WARNING: This feature is experimental/unstable.

Resets the cache for the path, or all the paths if path is nil.

Parameters:
- {path} (string?) path to reset

Lua module: vim.log vim.log

The vim.log module provides file-backed logger instances.

Use vim.log.new() to create a logger, it exposes five writer functions: trace(), debug(), info(), warn(), and error(). They are correspond to log levels defined by vim.log.levels.

Example:

```
local log = vim.log.new({ name = 'my-plugin', })
-- By default, logs will be written to {name}.log under `stdpath('log')`.

log.error('request failed', 'timeout')
-- This will write a line like the following to the log file:
--   [ERROR][2024-01-01 12:00:00] source.lua:123    request failed    timeout

-- Set the log level to `INFO`, otherwise the `info()` call below would be ignored,
-- since the default level is `WARN`.
vim.log.set_level(log, vim.log.levels.INFO)
log.info('starting', { buf = vim.api.nvim_get_current_buf() })
-- This will write a line like the following to the log file:
--   [INFO][2024-01-01 12:01:00] source.lua:124    starting    { buf = 1 }
```

You can also provide a custom formatter function to customize the log output format.

vim.Log

Fields:
- {debug} (fun(...:any): boolean?) Writes a message at vim.log.levels.DEBUG.
- {error} (fun(...:any): boolean?) Writes a message at vim.log.levels.ERROR.
- {info} (fun(...:any): boolean?) Writes a message at vim.log.levels.INFO.
- {trace} (fun(...:any): boolean?) Writes a message at vim.log.levels.TRACE.
- {warn} (fun(...:any): boolean?) Writes a message at vim.log.levels.WARN.

get_level({log}) vim.log.get_level()
Gets the current log level.

Parameters:
- {log} (vim.Log)

Return:
(vim.log.levels)

new({opts}) vim.log.new()
Creates a logger instance.

The logger writes formatted messages to a file, using a per-instance log level and formatting function.

Parameters:
- {opts} (table) A table with the following fields:
  - {format_func}? (fun(min_level: vim.log.levels, level: vim.log.levels, ...): string?) Formatter used for each log entry. Receives the logger's minimum level, the message level, and the values passed to the writer. Return a string to write an entry, or nil to skip it.
  - {level}? (vim.log.levels, default: vim.log.levels.WARN) Minimum level that will be written.
  - {name} (string) Display name used in notifications emitted by the logger.

Return:
(vim.Log)

set_format_func({log}, {func}) vim.log.set_format_func()
Sets the formatter used to produce log entries.

The formatter receives the logger's minimum level, the message level, and the values passed to the writer method. Return a string to write an entry, or nil to skip it.

Parameters:
- {log} (vim.Log)
- {func} (fun(min_level: vim.log.levels, level: vim.log.levels, ...): string?)

set_level({log}, {level}) vim.log.set_level()
Sets the current log level.

Entries below this level are skipped.

Parameters:
- {log} (vim.Log)
- {level} (vim.log.levels)

Lua module: vim.lpeg

vim.lpeg

LPeg is a pattern-matching library for Lua, based on Parsing Expression Grammars (PEGs). https://bford.info/packrat/

lua-lpeg vim.lpeg.Pattern The LPeg library for parsing expression grammars is included as `vim.lpeg` (https://www.inf.puc-rio.br/~roberto/lpeg/).

In addition, its regex-like interface is available as vim.re (https://www.inf.puc-rio.br/~roberto/lpeg/re.html).

Pattern:match({subject}, {init}, {...}) Pattern:match()

Matches the given `pattern` against the `subject` string. If the match succeeds, returns the index in the subject of the first character after the match, or the captured values (if the pattern captured any value). An optional numeric argument `init` makes the match start at that position in the subject string. As usual in Lua libraries, a negative value counts from the end. Unlike typical pattern-matching functions, `match` works only in anchored mode; that is, it tries to match the pattern with a prefix of the given subject string (at position `init`), not with an arbitrary substring of the subject. So, if we want to find a pattern anywhere in a string, we must either write a loop in Lua or write a pattern that matches anywhere.

Example:

```
local pattern = lpeg.R('az') ^ 1 * -1
assert(pattern:match('hello') == 6)
assert(lpeg.match(pattern, 'hello') == 6)
assert(pattern:match('1 hello') == nil)
```

Parameters:

- `{subject}` (`string`)
- `{init}` (`integer?`)
- `{...}` (`any`)

Return:

(`any`) ...

vim.lpeg.B({pattern}) vim.lpeg.B()

Returns a pattern that matches only if the input string at the current position is preceded by `patt`. Pattern `patt` must match only strings with some fixed length, and it cannot contain captures. Like the and predicate, this pattern never consumes any input, independently of success or failure.

Parameters:

- `{pattern}` (`vim.lpeg.Pattern|string|integer|boolean|table`)

Return:

(`vim.lpeg.Pattern`)

vim.lpeg.C({patt}) vim.lpeg.C()

Creates a simple capture, which captures the substring of the subject that matches `patt`. The captured value is a string. If `patt` has other captures, their values are returned after this one.

Example:

```
local function split (s, sep)
  sep = lpeg.P(sep)
  local elem = lpeg.C((1 - sep) ^ 0)
  local p = elem * (sep * elem) ^ 0
  return lpeg.match(p, s)
end
local a, b, c = split('a,b,c', ',')
assert(a == 'a')
assert(b == 'b')
assert(c == 'c')
```

Parameters:

- `{patt}` (`vim.lpeg.Pattern|string|integer|boolean|table|function`)

Return:

(`vim.lpeg.Capture`)

vim.lpeg.Carg({n}) vim.lpeg.Carg()

Creates an argument capture. This pattern matches the empty string and produces the value given as the nth extra argument given in the call to `lpeg.match`.

Parameters:

- `{n}` (`integer`)

Return:

(`vim.lpeg.Capture`)

vim.lpeg.Cb({name}) vim.lpeg.Cb()

Creates a back capture. This pattern matches the empty string and produces the values produced by the most recent group capture named `name` (where `name` can be any Lua value). Most recent means the last complete outermost group capture with the given name. A Complete capture means that the entire pattern corresponding to the capture has matched. An Outermost capture means that the capture is not inside another complete capture. In the same way that LPeg does not specify when it evaluates captures, it does not specify whether it reuses values previously produced by the group or re-evaluates them.

Parameters:

- `{name}` (`any`)

Return:

(`vim.lpeg.Capture`)

vim.lpeg.Cc({...}) vim.lpeg.Cc()
Creates a constant capture. This pattern matches the empty string and produces all given values as its captured values.

Parameters:
- {...} (any)

Return:
(vim.lpeg.Capture)

vim.lpeg.Cf({patt}, {func}) vim.lpeg.Cf()
Creates a fold capture. If patt produces a list of captures C1 C2 ... Cn, this capture will produce the value func(...func(func(C1, C2), C3)...,Cn), that is, it will fold (or accumulate, or reduce) the captures from patt using function func. This capture assumes that patt should produce at least one capture with at least one value (of any type), which becomes the initial value of an accumulator. (If you need a specific initial value, you may prefix a constant capture to patt.) For each subsequent capture, LPeg calls func with this accumulator as the first argument and all values produced by the capture as extra arguments; the first result from this call becomes the new value for the accumulator. The final value of the accumulator becomes the captured value.

Example:

```
local number = lpeg.R('09') ^ 1 / tonumber
local list = number * (',' * number) ^ 0
local function add(acc, newvalue) return acc + newvalue end
local sum = lpeg.Cf(list, add)
assert(sum:match('10,30,43') == 83)
```

Parameters:
- {patt} (vim.lpeg.Pattern|string|integer|boolean|table|function)
- {func} (fun(acc, newvalue))

Return:
(vim.lpeg.Capture)

vim.lpeg.Cg({patt}, {name}) vim.lpeg.Cg()
Creates a group capture. It groups all values returned by patt into a single capture. The group may be anonymous (if no name is given) or named with the given name (which can be any non-nil Lua value).

Parameters:
- {patt} (vim.lpeg.Pattern|string|integer|boolean|table|function)
- {name} (string?)

Return:
(vim.lpeg.Capture)

vim.lpeg.Cmt({patt}, {fn}) vim.lpeg.Cmt()
Creates a match-time capture. Unlike all other captures, this one is evaluated immediately when a match occurs (even if it is part of a larger pattern that fails later). It forces the immediate evaluation of all its nested captures and then calls function. The given function gets as arguments the entire subject, the current position (after the match of patt), plus any capture values produced by patt. The first value returned by function defines how the match happens. If the call returns a number, the match succeeds and the returned number becomes the new current position. (Assuming a subject sand current position i, the returned number must be in the range [i, len(s) + 1].) If the call returns true, the match succeeds without consuming any input (so, to return true is equivalent to return i). If the call returns false, nil, or no value, the match fails. Any extra values returned by the function become the values produced by the capture.

Parameters:
- {patt} (vim.lpeg.Pattern|string|integer|boolean|table|function)
- {fn} (fun(s: string, i: integer, ...: any)) (position: boolean|integer, ...: any)

Return:
(vim.lpeg.Capture)

vim.lpeg.Cp() vim.lpeg.Cp()
Creates a position capture. It matches the empty string and captures the position in the subject where the match occurs. The captured value is a number.

Example:

```
local I = lpeg.Cp()
local function anywhere(p) return lpeg.P({I * p * I + 1 * lpeg.V(1)}) end
local match_start, match_end = anywhere('world'):match('hello world!')
assert(match_start == 7)
assert(match_end == 12)
```

Return:
(vim.lpeg.Capture)

vim.lpeg.Cs({patt}) vim.lpeg.Cs()
Creates a substitution capture. This function creates a substitution capture, which captures the substring of the subject that matches patt, with substitutions. For any capture inside patt with a value, the substring that matched the capture is replaced by the capture value (which should be a string). The final captured value is the string resulting from all replacements.

Example:

```
local function gsub (s, patt, repl)
  patt = lpeg.P(patt)
  patt = lpeg.Cs((patt / repl + 1) ^ 0)
  return lpeg.match(patt, s)
end
assert(gsub('Hello, xxx!', 'xxx', 'World') == 'Hello, World!')
```

Parameters:
- {patt} (vim.lpeg.Pattern|string|integer|boolean|table|function)

Return:
(vim.lpeg.Capture)

vim.lpeg.Ct({patt}) vim.lpeg.Ct()
Creates a table capture. This capture returns a table with all values from all anonymous captures made by patt inside this table in successive integer keys, starting at 1. Moreover, for each named capture group created by patt, the first value of the group is put into the table with the group name as its key. The captured value is only the table.

Parameters:
- {patt} (vim.lpeg.Pattern|string|integer|boolean|table|function)

Return:
(vim.lpeg.Capture)

vim.lpeg.locale({tab}) vim.lpeg.locale()
Returns a table with patterns for matching some character classes according to the current locale. The table has fields named alnum, alpha, cntrl, digit, graph, lower, print, punct, space, upper, and xdigit, each one containing a correspondent pattern. Each pattern matches any single character that belongs to its class. If called with an argument table, then it creates those fields inside the given table and returns that table.

Example:

```
lpeg.locale(lpeg)
local space = lpeg.space ^ 0
local name = lpeg.C(lpeg.alpha ^ 1) * space
local sep = lpeg.S(',;') * space
local pair = lpeg.Cg(name * '=' * space * name) * sep ^ -1
local list = lpeg.Cf(lpeg.Ct('') * pair ^ 0, rawset)
local t = list:match('a=b, c = hi; next = pi')
assert(t.a == 'b')
assert(t.c == 'hi')
assert(t.next == 'pi')
local locale = lpeg.locale()
assert(type(locale.digit) == 'userdata')
```

Parameters:
- {tab} (table?)

Return:
(vim.lpeg.Locale)

vim.lpeg.match({pattern}, {subject}, {init}, {...}) vim.lpeg.match()
Matches the given pattern against the subject string. If the match succeeds, returns the index in the subject of the first character after the match, or the captured values (if the pattern captured any value). An optional numeric argument init makes the match start at that position in the subject string. As usual in Lua libraries, a negative value counts from the end. Unlike typical pattern-matching functions, match works only in anchored mode; that is, it tries to match the pattern with a prefix of the given subject string (at position init), not with an arbitrary substring of the subject. So, if we want to find a pattern anywhere in a string, we must either write a loop in Lua or write a pattern that matches anywhere.

Example:

```
local pattern = lpeg.R('az') ^ 1 * -1
assert(pattern:match('hello') == 6)
assert(lpeg.match(pattern, 'hello') == 6)
assert(pattern:match('1 hello') == nil)
```

Parameters:
- {pattern} (vim.lpeg.Pattern|string|integer|boolean|table|function)
- {subject} (string)
- {init} (integer?)
- {...} (any)

Return:
(any) ...

vim.lpeg.P({value}) vim.lpeg.P()
Converts the given value into a proper pattern. The following rules are applied:
- If the argument is a pattern, it is returned unmodified.
- If the argument is a string, it is translated to a pattern that matches the string literally.
- If the argument is a non-negative number n, the result is a pattern that matches exactly n characters.
- If the argument is a negative number -n, the result is a pattern that succeeds only if the input string has less than n characters left: lpeg.P(-n) is equivalent to -lpeg.P(n) (see the unary minus operation).
- If the argument is a boolean, the result is a pattern that always succeeds or always fails (according to the boolean value), without consuming any input.
- If the argument is a table, it is interpreted as a grammar (see Grammars).
- If the argument is a function, returns a pattern equivalent to a match-time capture over the empty string.

Parameters:
- {value} (vim.lpeg.Pattern|string|integer|boolean|table|function)

Return:
(vim.lpeg.Pattern)

vim.lpeg.R({...}) vim.lpeg.R()
Returns a pattern that matches any single character belonging to one of the given ranges. Each range is a string xy of length 2, representing

all characters with code between the codes of x and y (both inclusive). As an example, the pattern `lpeg.R('09')` matches any digit, and `lpeg.R('az', 'AZ')` matches any ASCII letter.

Example:

```
local pattern = lpeg.R('az') ^ 1 * -1
assert(pattern:match('hello') == 6)
```

Parameters:
- `{...}` (`string`)

Return:
(`vim.lpeg.Pattern`)

vim.lpeg.S({`string`}) vim.lpeg.S()
Returns a pattern that matches any single character that appears in the given string (the S stands for Set). As an example, the pattern `lpeg.S('+-*/')` matches any arithmetic operator. Note that, if `s` is a character (that is, a string of length 1), then `lpeg.P(s)` is equivalent to `lpeg.S(s)` which is equivalent to `lpeg.R(s..s)`. Note also that both `lpeg.S('')` and `lpeg.R()` are patterns that always fail.

Parameters:
- `{string}` (`string`)

Return:
(`vim.lpeg.Pattern`)

vim.lpeg.setmaxstack({`max`}) vim.lpeg.setmaxstack()
Sets a limit for the size of the backtrack stack used by LPeg to track calls and choices. The default limit is `400`. Most well-written patterns need little backtrack levels and therefore you seldom need to change this limit; before changing it you should try to rewrite your pattern to avoid the need for extra space. Nevertheless, a few useful patterns may overflow. Also, with recursive grammars, subjects with deep recursion may also need larger limits.

Parameters:
- `{max}` (`integer`)

vim.lpeg.type({`value`}) vim.lpeg.type()
Returns the string `"pattern"` if the given value is a pattern, otherwise `nil`.

Parameters:
- `{value}` (`vim.lpeg.Pattern|string|integer|boolean|table|function`)

Return:
(`"pattern"?`)

vim.lpeg.V({`v`}) vim.lpeg.V()
Creates a non-terminal (a variable) for a grammar. This operation creates a non-terminal (a variable) for a grammar. The created non-terminal refers to the rule indexed by `v` in the enclosing grammar.

Example:

```
local b = lpeg.P({'(' * ((1 - lpeg.S '()') + lpeg.V(1)) ^ 0 * ')'})
assert(b:match('((string))') == 11)
assert(b:match('(') == nil)
```

Parameters:
- `{v}` (`boolean|string|number|function|table|thread|userdata|lightuserdata`)

Return:
(`vim.lpeg.Pattern`)

vim.lpeg.version() vim.lpeg.version()
Returns a string with the running version of LPeg.

Return:
(`string`)

Lua module: vim.mpack vim.mpack

This module provides encoding and decoding of Lua objects to and from msgpack-encoded strings. Supports vim.NIL and vim.empty_dict().

vim.mpack.decode({`str`}) vim.mpack.decode()
Decodes (or "unpacks") the msgpack-encoded `{str}` to a Lua object.

Parameters:
- `{str}` (`string`)

Return:
(`any`)

vim.mpack.encode({`obj`}) vim.mpack.encode()
Encodes (or "packs") Lua object `{obj}` as msgpack in a Lua string.

Parameters:
- `{obj}` (`any`)

Return:
(`string`)

Lua module: vim.net vim.net

vim.net.request.Response

Fields:
- {body} (string) The HTTP body of the request

vim.net.request()

vim.net.request({method}, {url}, {opts}, {on_response}) Makes an HTTP request to the given URL, asynchronously passing the result to the specified on_response, outpath or outbuf.

Examples:

```
-- Write response body to file.
vim.net.request('https://neovim.io/charter/', {
  outpath = 'vision.html',
})

-- Process the response.
vim.net.request(
  'https://api.github.com/repos/neovim/neovim',
  {},
  function (err, res)
    if err then return end
    local stars = vim.json.decode(res.body).stargazers_count
    vim.print(('Neovim currently has %d stars'):format(stars))
  end
)

-- Write to both file and current buffer, but cancel it.
local job = vim.net.request('https://neovim.io/charter/', {
  outpath = 'vision.html',
  outbuf = 0,
})
job:close()

-- Add custom headers in the request.
vim.net.request('https://neovim.io/charter/', {
  headers = { Authorization = 'Bearer XYZ' },
})

-- POST request with body.
vim.net.request('POST', 'https://example.com/api', {
  body = '{"key": "value"}',
  headers = {['Content-Type'] = 'application/json' }
})
```

Parameters:
- {method} (vim.net.HttpMethod) (default: GET) The HTTP method (GET, POST, PUT, PATCH, HEAD, DELETE).
- {url} (string) The URL for the request.
- {opts} (table?) A table with the following fields:
  - {body}? (string) Request body for POST/PUT/PATCH requests.
  - {headers}? (table<string, string>) Custom headers to send with the request. Supports basic key/value headers and empty headers as supported by curl. Does not support "@filename" style, internal header deletion ("Header:").
  - {outbuf}? (integer) Buffer to save the response body to.
  - {outpath}? (string) File path to save the response body to.
  - {retry}? (integer) Number of retries on transient failures (default: 3).
  - {verbose}? (boolean) Enables verbose output.
- {on_response} (vim.net.request.ResponseFunc?) Callback invoked on request completion.

Overloads:
- fun(url: string, opts: vim.net.request.Opts, response: vim.net.request.ResponseFunc)
- fun(method: vim.net.HttpMethod, url: string, opts: vim.net.request.Opts, response: vim.net.request.ResponseFunc)

Return:
({ close: fun() }) Object with close() method which cancels the request.

Lua module: vim.pos

vim.pos

EXPERIMENTAL: This API is unstable, do not use it. Its semantics are not yet finalized. Subscribe to this issue to stay updated: https://github.com/neovim/neovim/issues/25509

Provides operations to compare, calculate, and convert positions represented by vim.Pos objects.

vim.Pos Represents a buffer position based on api-indexing (0-indexed, end-exclusive ranges). Call vim.pos() to create a new vim.Pos by passing the {buf}, {row}, and {col} of a position.

Example:

```
local pos1 = vim.pos(0, 3, 5)
local pos2 = vim.pos(0, 4, 0)

-- Operators are overloaded for comparing two `vim.Pos` objects.
if pos1 < pos2 then
  print("pos1 comes before pos2")
end

if pos1 ~= pos2 then
  print("pos1 and pos2 are different positions")
end
```

It may include optional fields that enable additional capabilities, such as format conversions.

Fields:
- {buf} (integer) buffer handle.
- {col} (integer) 0-based byte index.
- {row} (integer) 0-based byte index.

cursor({buf}, {pos}) vim.pos.cursor()
Creates a new vim.Pos from cursor position (see api-indexing).

If {pos} is omitted, the first argument is treated as {win} instead of {buf}, and the current cursor position of {win} is used. If {win} is also omitted, it defaults to the current window.

Example:

```
local buf = vim.api.nvim_win_get_buf(0)
local cursor_pos = vim.api.nvim_win_get_cursor(0)
local pos = vim.pos.cursor(buf, cursor_pos)
-- This is equivalent:
local pos = vim.pos.cursor(0)
```

Parameters:
- {buf} (integer)
- {pos} ([integer, integer]) (lnum, col) tuple

Overloads:
- fun(win?: integer): vim.Pos

Return:
(vim.Pos)

extmark({buf}, {row}, {col}) vim.pos.extmark()
Creates a new vim.Pos from extmark position (see api-indexing).

Example:

```
local pos = vim.pos.extmark(0, 3, 5)
```

Parameters:
- {buf} (integer)
- {row} (integer)
- {col} (integer)

Return:
(vim.Pos)

lsp({buf}, {pos}, {position_encoding}) vim.pos.lsp()
Creates a new vim.Pos from lsp.Position.

Example:

```
local lsp_pos = {
  line = 3,
  character = 5
}

local pos = vim.pos.lsp(0, lsp_pos, 'utf-16')
```

Parameters:
- {buf} (integer)
- {pos} (lsp.Position)
- {position_encoding} (lsp.PositionEncodingKind)

Return:
(vim.Pos)

mark({buf}, {lnum}, {col}) vim.pos.mark()
Creates a new vim.Pos from mark position (see api-indexing).

Example:

```
local mark_info = vim.api.nvim_get_mark('M')
local lnum, col, buf, name = unpack(mark_info)

if lnum == 0 and col == 0 and buf == 0 then
  return -- mark 'M' is not set.
end

local pos = vim.pos.mark(buf, lnum, col)
```

Parameters:
- {buf} (integer)
- {lnum} (integer)
- {col} (integer)

Return:
(vim.Pos)

offset({buf}, {offset}) vim.pos.offset()
Creates a new vim.Pos from buffer (bytes) offset.

Example:

```
local offset = vim.api.nvim_buf_get_offset(0, vim.api.nvim_buf_line_count(0))
local pos = vim.pos.offset(0, offset)
```

Parameters:
- {buf} (integer)
- {offset} (integer)

Return:
(vim.Pos)

to_cursor({pos}) vim.pos.to_cursor()
Converts vim.Pos to cursor position (see api-indexing).

Example:

```
local pos = vim.pos(0, 3, 5)

-- Convert to cursor position, you can call it in a method style.
local cursor_pos = pos:to_cursor()
vim.api.nvim_win_set_cursor(0, cursor_pos)
```

Parameters:
- {pos} (vim.Pos)

Return:
([integer, integer]) (lnum, col) tuple

to_extmark({pos}) vim.pos.to_extmark()
Converts vim.Pos to extmark position (see api-indexing).

Example:

```
local pos = vim.pos(0, 3, 5)

-- Convert to extmark position, you can call it in a method style.
local extmark_pos = pos:to_extmark()
```

Parameters:
- {pos} (vim.Pos)

Return (multiple):
(integer) row (integer) col

to_lsp({pos}, {position_encoding}) vim.pos.to_lsp()
Converts vim.Pos to lsp.Position.

Example:

```
local pos = vim.pos(0, 3, 5)

-- Convert to LSP position, you can call it in a method style.
local lsp_pos = pos:to_lsp('utf-16')
```

Parameters:
- {pos} (vim.Pos)
- {position_encoding} (lsp.PositionEncodingKind)

Return:
(lsp.Position)

to_mark({pos}) vim.pos.to_mark()
Converts vim.Pos to mark position (see api-indexing).

Example:

```
local pos = vim.pos(0, 3, 5)

-- Convert to mark position, you can call it in a method style.
local lnum, col = pos:to_mark()
vim.api.nvim_buf_set_mark(0, 'M', lnum, col)
```

Parameters:
- {pos} (vim.Pos)

Return (multiple):
(integer) lnum (integer) col

to_offset({pos}) vim.pos.to_offset()
Converts vim.Pos to buffer (bytes) offset.

Example:

```
local p1 = vim.pos(0, 3, 5)
local p2 = vim.pos(0, 4, 0)

-- Convert to buffer offset, you can call it in a method style.
local offset1 = p1:to_offset()
local offset2 = p2:to_offset()
-- Can be used to calculate the distance between two locations.
local distance = offset2 - offset1
```

Parameters:
- {pos} (vim.Pos)

Return:
(integer)

Lua module: vim.range

vim.range

EXPERIMENTAL: This API is unstable, do not use it. Its semantics are not yet finalized. Subscribe to this issue to stay updated: https://github.com/neovim/neovim/issues/25509

Provides operations to compare, calculate, and convert ranges represented by vim.Range objects.

vim.Range Represents a range based on api-indexing (0-indexed, end-exclusive). Call `vim.range()` to create a new range by passing start and end positions (vim.Pos).

Both positions must have the same optional fields, which may enable additional capabilities (such as format conversions).

Example:

```
local pos1 = vim.pos(0, 3, 5)
local pos2 = vim.pos(0, 4, 0)

-- Create a range from two positions.
local range1 = vim.range(pos1, pos2)
-- Or create a range from four integers representing start and end positions.
local range2 = vim.range(0, 3, 5, 4, 0)

-- Because `vim.Range` is end exclusive, `range1` and `range2` both represent
-- a range starting at the row 3, column 5 and ending at where the row 3 ends
-- (including the newline at the end of line 3).

-- Operators are overloaded for comparing two `vim.Pos` objects.
if range1 == range2 then
  print("range1 and range2 are the same range")
end
```

Fields:
- {buf} (integer) Optional buffer handle.
- {end_col} (integer) 0-based byte index.
- {end_row} (integer) 0-based byte index.
- {start_col} (integer) 0-based byte index.
- {start_row} (integer) 0-based byte index.

vim.range.extmark()

extmark({buf}, {start_row}, {start_col}, {end_row}, {end_col}) Creates a new vim.Range from extmark range (see api-indexing).

Example:

```
local range = vim.range.extmark(0, 3, 5, 4, 0)
```

Parameters:
- {buf} (integer)
- {start_row} (integer)
- {start_col} (integer)
- {end_row} (integer)
- {end_col} (integer)

Return:
(vim.Range)

has({outer}, {inner}) vim.range.has()

Checks whether {outer} range contains {inner} range or position.

Parameters:
- {outer} (vim.Range)
- {inner} (vim.Range|vim.Pos)

Return:
(boolean) `true` if {outer} range fully contains {inner} range or position.

intersect({r1}, {r2}) vim.range.intersect()

Computes the common range shared by the given ranges.

Parameters:
- {r1} (vim.Range) First range to intersect.
- {r2} (vim.Range) Second range to intersect

Return:
(vim.Range?) range that is present inside both `r1` and `r2`. `nil` if such range does not exist.

is_empty({range}) vim.range.is_empty()
Checks whether the given range is empty; i.e., start >= end.

Parameters:
- {range} (vim.Range)

Return:
(boolean) true if the given range is empty.

lsp({buf}, {range}, {position_encoding}) vim.range.lsp()
Creates a new vim.Range from lsp.Range.

Example:

```
local lsp_range = {
  ['start'] = { line = 3, character = 5 },
  ['end'] = { line = 4, character = 0 }
}

local range = vim.range.lsp(0, lsp_range, 'utf-16')
```

Parameters:
- {buf} (integer)
- {range} (lsp.Range)
- {position_encoding} (lsp.PositionEncodingKind)

Return:
(vim.Range)

vim.range.mark()
mark({buf}, {start_lnum}, {start_col}, {end_lnum}, {end_col}) Creates a new vim.Range from "mark-indexed" range (see api-indexing).

Example:

```
-- A range represented by marks may be end-inclusive (decided by 'selection' option).
local start_lnum, start_col = unpack(api.nvim_buf_get_mark(bufnr, '<'))
local end_lnum, end_col = unpack(api.nvim_buf_get_mark(bufnr, '>'))

-- Create an end-exclusive range.
local range = vim.range.mark(0, start_lnum, start_col, end_lnum, end_col)
```

Parameters:
- {buf} (integer)
- {start_lnum} (integer)
- {start_col} (integer)
- {end_lnum} (integer)
- {end_col} (integer)

Return:
(vim.Range)

to_extmark({range}) vim.range.to_extmark()
Converts vim.Range to extmark range (see api-indexing).

Example:

```
local range = vim.range(0, 3, 5, 4, 0)

-- Convert to extmark range, you can call it in a method style.
local extmark_range = range:to_extmark()
```

Parameters:
- {range} (vim.Range)

Return (multiple):
(integer) start_row (integer) start_col (integer) end_row (integer) end_col

to_lsp({range}, {position_encoding}) vim.range.to_lsp()
Converts vim.Range to lsp.Range.

Example:

```
local range = vim.range(0, 3, 5, 4, 0)

-- Convert to LSP range, you can call it in a method style.
local lsp_range = range:to_lsp('utf-16')
```

Parameters:
- {range} (vim.Range)
- {position_encoding} (lsp.PositionEncodingKind)

Return:
(lsp.Range)

to_mark({range}) vim.range.to_mark()
Converts vim.Range to extmark range (see api-indexing).

Example:

```
local range = vim.range(0, 3, 5, 4, 0)

-- Convert to mark range, you can call it in a method style.
local start_lnum, start_col, end_lnum, end_col = range:to_mark()
```

Parameters:
- {range} (vim.Range)

Return (multiple):
(integer) start_lnum (integer) start_col (integer) end_lnum (integer) end_col

Lua module: vim.re

vim.re

The vim.re module provides a conventional regex-like syntax for pattern usage within LPeg vim.lpeg. (Unrelated to vim.regex which provides Vim regexp from Lua.)

See https://www.inf.puc-rio.br/~roberto/lpeg/re.html for the original documentation including regex syntax and examples.

vim.re.compile({string}, {defs}) vim.re.compile()
Compiles the given {string} and returns an equivalent LPeg pattern. The given string may define either an expression or a grammar. The optional {defs} table provides extra Lua values to be used by the pattern.

Parameters:
- {string} (string)
- {defs} (table?)

Return:
(vim.lpeg.Pattern)

vim.re.find({subject}, {pattern}, {init}) vim.re.find()
Searches the given {pattern} in the given {subject}. If it finds a match, returns the index where this occurrence starts and the index where it ends. Otherwise, returns nil.

An optional numeric argument {init} makes the search starts at that position in the subject string. As usual in Lua libraries, a negative value counts from the end.

Parameters:
- {subject} (string)
- {pattern} (vim.lpeg.Pattern|string)
- {init} (integer?)

Return (multiple):
(integer?) the index where the occurrence starts, nil if no match (integer?) the index where the occurrence ends, nil if no match

vim.re.gsub({subject}, {pattern}, {replacement}) vim.re.gsub()
Does a global substitution, replacing all occurrences of {pattern} in the given {subject} by {replacement}.

Parameters:
- {subject} (string)
- {pattern} (vim.lpeg.Pattern|string)
- {replacement} (string)

Return:
(string)

vim.re.match({subject}, {pattern}, {init}) vim.re.match()
Matches the given {pattern} against the given {subject}, returning all captures.

Parameters:
- {subject} (string)
- {pattern} (vim.lpeg.Pattern|string)
- {init} (integer?)

Return:
(integer|vim.lpeg.Capture?)

See also:
- vim.lpeg.match()

vim.re.updatelocale() vim.re.updatelocale()
Updates the pre-defined character classes to the current locale.

Lua module: vim.regex

vim.regex

The vim.regex interface allows Lua code to use Vim regexes.
- Matches within a single line.
- Does not check for interrupts (CTRL-C), so can be used from an api-fast context.

regex:match_line()
regex:match_line({buf}, {line_idx}, {start}, {end_}) Matches line at line_idx (zero-based) in buffer buf. Match is restricted to byte index range start and end_ if given, otherwise see regex:match_str(). Returned byte indices are relative to start if given.

Parameters:
- {buf} (integer)
- {line_idx} (integer)
- {start} (integer?)
- {end_} (integer?)

Return (multiple):
(`integer?`) match start (byte index) relative to `start`, or `nil` if no match (`integer?`) match end (byte index) relative to `start`, or `nil` if no match

regex:match_str({str}) regex:match_str()
Matches string `str` against this regex. To match the string precisely, surround the regex with "^" and "$". Returns the byte indices for the start and end of the match, or `nil` if there is no match. Because any integer is "truthy", `regex:match_str()` can be directly used as a condition in an if-statement.

Parameters:
- `{str}` (`string`)

Return (multiple):
(`integer?`) match start (byte index), or `nil` if no match (`integer?`) match end (byte index), or `nil` if no match

vim.regex({re}) vim.regex()
Parses the Vim regex `re` and returns a regex object. Regexes are "magic" and case-sensitive by default, regardless of 'magic' and 'ignorecase'. They can be controlled with flags, see /magic and /ignorecase.

Parameters:
- `{re}` (`string`)

Return:
(`vim.regex`)

Lua module: vim.secure vim.secure

vim.secure.read({path}) vim.secure.read()
If `{path}` is a file: attempt to read the file, prompting the user if the file should be trusted.

If `{path}` is a directory: return true if the directory is trusted (non-recursive), prompting the user as necessary.

The user's choice is persisted in a trust database at $XDG_STATE_HOME/nvim/trust.

Attributes:
Since: 0.9.0

Parameters:
- `{path}` (`string`) Path to a file or directory to read.

Return:
(`boolean|string?`) If `{path}` is not trusted or does not exist, returns `nil`. Otherwise, returns the contents of `{path}` if it is a file, or true if `{path}` is a directory.

See also:
- :trust

vim.secure.trust({opts}) vim.secure.trust()
Manage the trust database.

The trust database is located at $XDG_STATE_HOME/nvim/trust.

Attributes:
Since: 0.9.0

Parameters:
- `{opts}` (`table`) A table with the following fields:
  - `{action}` (`'allow'|'deny'|'remove'`) One of:
    - `'allow'` to add a file to the trust database and trust it,
    - `'deny'` to add a file to the trust database and deny it,
    - `'remove'` to remove file from the trust database
  - `{bufnr}?` (`integer`) Buffer number to update. Mutually exclusive with `{path}`.
  - `{path}?` (`string`) Path to a file to update. Mutually exclusive with `{bufnr}`.

Return (multiple):
(`boolean`) success true if operation was successful (`string`) msg full path if operation was successful, else error message

Lua module: vim.snippet vim.snippet

Snippet expansion and navigation.

Internal autocmds live in the `nvim.snippet` augroup. To disable them (e.g. to manage sessions yourself), clear it:

```
vim.api.nvim_clear_autocmds({ group = 'nvim.snippet', buffer = 0 })
```

Heads-up: vim.snippet.jump() re-registers them on every jump.

vim.snippet.ActiveFilter

Fields:
- `{direction}` (`vim.snippet.Direction`) Navigation direction. -1 for previous, 1 for next.

vim.snippet.active({filter}) vim.snippet.active()
Returns `true` if there's an active snippet in the current buffer, applying the given filter if provided.

Parameters:
- `{filter}` (`vim.snippet.ActiveFilter?`) Filter to constrain the search with:
  - `direction` (vim.snippet.Direction): Navigation direction. Will return `true` if the snippet can be jumped in the given direction.

Return:

(boolean)

vim.snippet.expand({input}) vim.snippet.expand()
Expands the given snippet text. Refer to https://microsoft.github.io/language-server-protocol/specification/#snippet_syntax for the specification of valid input.

Tabstops are highlighted with hl-SnippetTabstop and hl-SnippetTabstopActive.

Parameters:
- {input} (string)

vim.snippet.jump({direction}) vim.snippet.jump()
Jumps to the next (or previous) placeholder in the current snippet, if possible.

By default <Tab> is setup to jump if a snippet is active. The default mapping looks like:

```
vim.keymap.set({ 'i', 's' }, '<Tab>', function()
   if vim.snippet.active({ direction = 1 }) then
     return '<Cmd>lua vim.snippet.jump(1)<CR>'
   else
     return '<Tab>'
   end
 end, { desc = '...', expr = true, silent = true })
```

Parameters:
- {direction} (vim.snippet.Direction) Navigation direction. -1 for previous, 1 for next.

vim.snippet.stop() vim.snippet.stop()
Exits the current snippet.

Lua module: vim.spell vim.spell

vim.spell.check({str}) vim.spell.check()
Check {str} for spelling errors. Similar to the Vimscript function spellbadword().

Note: The behaviour of this function is dependent on: 'spelllang', 'spellfile', 'spellcapcheck' and 'spelloptions' which can all be local to the buffer. Consider calling this with nvim_buf_call().

Example:

```
vim.spell.check("the quik brown fox")
-- =>
-- {
--     {'quik', 'bad', 5}
-- }
```

Parameters:
- {str} (string)

Return:
([string, 'bad'|'rare'|'local'|'caps', integer][]) List of tuples with three items:
- The badly spelled word.
- The type of the spelling error: "bad" spelling mistake "rare" rare word "local" word only valid in another region "caps" word should start with Capital
- The position in {str} where the word begins.

Lua module: vim.system lua-vim-system

vim.SystemCompleted

Fields:
- {code} (integer)
- {signal} (integer)
- {stderr}? (string) nil if stderr is disabled or has a custom handler.
- {stdout}? (string) nil if stdout is disabled or has a custom handler.

vim.SystemObj

Fields:
- {cmd} (string[]) Command name and args
- {is_closing} (fun(self: vim.SystemObj): boolean) See SystemObj:is_closing().
- {kill} (fun(self: vim.SystemObj, signal: integer|string)) See SystemObj:kill().
- {pid} (integer) Process ID
- {wait} (fun(self: vim.SystemObj, timeout: integer?): vim.SystemCompleted) See SystemObj:wait().
- {write} (fun(self: vim.SystemObj, data: string[]|string?)) See SystemObj:write().

SystemObj:is_closing() SystemObj:is_closing()
Checks if the process handle is closing or already closed.

This method returns true if the underlying process handle is either nil or is in the process of closing. It is useful for determining whether it is safe to perform operations on the process handle.

Return:
(boolean)

SystemObj:kill({signal}) SystemObj:kill()
Sends a signal to the process.

The signal can be specified as an integer or as a string.

Example:

```
local obj = vim.system({'sleep', '10'})
obj:kill('sigterm') -- sends SIGTERM to the process
```

Parameters:
- {signal} (integer|string) Signal to send to the process. See luv-constants.

SystemObj:wait({timeout}) SystemObj:wait()
Waits for the process to complete or until the specified timeout elapses.

This method blocks execution until the associated process has exited or the optional timeout (in milliseconds) has been reached. If the process does not exit before the timeout, it is forcefully terminated with SIGKILL (signal 9), and the exit code is set to 124.

If no timeout is provided, the method will wait indefinitely (or use the timeout specified in the options when the process was started).

Example:

```
local obj = vim.system({'echo', 'hello'}, { text = true })
local result = obj:wait(1000) -- waits up to 1000ms
print(result.code, result.signal, result.stdout, result.stderr)
```

Parameters:
- {timeout} (integer?)

Return:
(vim.SystemCompleted)

SystemObj:write({data}) SystemObj:write()
Writes data to the stdin of the process or closes stdin.

If data is a list of strings, each string is written followed by a newline.

If data is a string, it is written as-is.

If data is nil, the write side of the stream is shut down and the pipe is closed.

Example:

```
local obj = vim.system({'cat'}, { stdin = true })
obj:write({'hello', 'world'}) -- writes 'hello\nworld\n' to stdin
obj:write(nil) -- closes stdin
```

Parameters:
- {data} (string[]|string?)

vim.system({cmd}, {opts}, {on_exit}) vim.system()
Runs a system command or throws an error if {cmd} cannot be run.

The command runs directly (not in 'shell') so shell builtins such as "echo" in cmd.exe, cmdlets in powershell, or "help" in bash, will not work unless you actually invoke a shell: vim.system({'bash', '-c', 'help'}).

Examples:

```
local on_exit = function(obj)
  print(obj.code)
  print(obj.signal)
  print(obj.stdout)
  print(obj.stderr)
end

-- Runs asynchronously:
vim.system({'echo', 'hello'}, { text = true }, on_exit)

-- Runs synchronously:
local obj = vim.system({'echo', 'hello'}, { text = true }):wait()
-- { code = 0, signal = 0, stdout = 'hello\n', stderr = '' }
```

See uv.spawn() for more details. **Note:** unlike uv.spawn(), vim.system throws an error if {cmd} cannot be run.

Parameters:
- {cmd} (string[]) Command to execute
- {opts} (table?) A table with the following fields:
  - {clear_env}? (boolean) env defines the job environment exactly, instead of merging current environment. **Note:** if env is nil, the current environment is used but without NVIM set.
  - {cwd}? (string) Set the current working directory for the sub-process.
  - {detach}? (boolean) Spawn the child process in a detached state - this will make it a process group leader, and will effectively enable the child to keep running after the parent exits. Note that the child process will still keep the parent's event loop alive unless the parent process calls uv.unref() on the child's process handle.
  - {env}? (table<string,string|number>) Set environment variables for the new process. Inherits the current environment with NVIM set to v:servername.
  - {stderr}? (fun(err:string?, data: string?)|boolean, default: true) Handle output from stderr.
  - {stdin}? (string|string[]|true) If true, then a pipe to stdin is opened and can be written to via the write() method to SystemObj. If string or string[] then will be written to stdin and closed.
  - {stdout}? (fun(err:string?, data: string?)|boolean, default: true) Handle output from stdout.
  - {text}? (boolean) Handle stdout and stderr as text. Normalizes line endings by replacing \r\n with \n.

- {timeout}? (integer) Run the command with a time limit in ms. Upon timeout the process is sent the TERM signal (15) and the exit code is set to 124.
- {on_exit} (fun(out: vim.SystemCompleted)?) Called when subprocess exits. When provided, the command runs asynchronously. See return of SystemObj:wait().

Overloads:
- fun(cmd: string[], on_exit: fun(out: vim.SystemCompleted)): vim.SystemObj

Return:
(vim.SystemObj)

Lua module: vim.text

vim.text

vim.text.diff({a}, {b}, {opts}) vim.text.diff()
Run diff on strings {a} and {b}. Any indices returned by this function, either directly or via callback arguments, are 1-based.

Examples:

```
vim.text.diff('a\n', 'b\nc\n')
-- =>
-- @@ -1 +1,2 @@
-- -a
-- +b
-- +c

vim.text.diff('a\n', 'b\nc\n', {result_type = 'indices'})
-- =>
-- {
--   {1, 1, 1, 2}
-- }
```

Parameters:
- {a} (string) First string to compare
- {b} (string) Second string to compare
- {opts} (table?) Optional parameters:
  - {algorithm}? ('myers'|'minimal'|'patience'|'histogram', default: 'myers') Diff algorithm to use. Values:
    - myers: the default algorithm
    - minimal: spend extra time to generate the smallest possible diff
    - patience: patience diff algorithm
    - histogram: histogram diff algorithm
  - {ctxlen}? (integer) Context length
  - {ignore_blank_lines}? (boolean) Ignore blank lines
  - {ignore_cr_at_eol}? (boolean) Ignore carriage return at end-of-line
  - {ignore_whitespace}? (boolean) Ignore whitespace
  - {ignore_whitespace_change}? (boolean) Ignore whitespace change
  - {ignore_whitespace_change_at_eol}? (boolean) Ignore whitespace change at end-of-line.
  - {indent_heuristic}? (boolean) Use the indent heuristic for the internal diff library.
  - {interhunkctxlen}? (integer) Inter hunk context length
  - {linematch}? (boolean|integer) Run linematch on the resulting hunks from xdiff. When integer, only hunks upto this size in lines are run through linematch. Requires result_type = indices, ignored otherwise.
  - {on_hunk}? (fun(start_a: integer, count_a: integer, start_b: integer, count_b: integer): integer?) Invoked for each hunk in the diff. Return a negative number to cancel the callback for any remaining hunks. Arguments:
    - start_a (integer): Start line of hunk in {a}.
    - count_a (integer): Hunk size in {a}.
    - start_b (integer): Start line of hunk in {b}.
    - count_b (integer): Hunk size in {b}.
  - {result_type}? ('unified'|'indices', default: 'unified') Form of the returned diff:
    - unified: String in unified format.
    - indices: Array of hunk locations. **Note:** This option is ignored if on_hunk is used.

Return:
(string|integer[][]?) See {opts.result_type}. nil if {opts.on_hunk} is given.

vim.text.hexdecode({enc}) vim.text.hexdecode()
Hex decode a string.

Parameters:
- {enc} (string) String to decode

Return (multiple):
(string?) Decoded string (string?) Error message, if any

vim.text.hexencode({str}) vim.text.hexencode()
Hex encode a string.

Parameters:
- {str} (string) String to encode

Return:
(string) Hex encoded string

vim.text.indent({size}, {text}, {opts}) vim.text.indent()
Sets the indent (i.e. the common leading whitespace) of non-empty lines in text to size spaces/tabs.

Indent is calculated by number of consecutive indent chars.

- The first indented, non-empty line decides the indent char (space/tab):
  - `SPC SPC TAB …` = two-space indent.
  - `TAB SPC …` = one-tab indent.
- Set `opts.expandtab` to treat tabs as spaces.

To "dedent" (remove the common indent), pass `size=0`:

```
vim.print(vim.text.indent(0, ' a\n  b\n'))
```

To adjust relative-to an existing indent, call indent() twice:

```
local indented, old_indent = vim.text.indent(0, ' a\n b\n')
indented = vim.text.indent(old_indent + 2, indented)
vim.print(indented)
```

To ignore the final, blank line when calculating the indent, use gsub() before calling indent():

```
local text = '  a\n  b\n '
vim.print(vim.text.indent(0, (text:gsub('\n[\t ]+\n?$', '\n'))))
```

Parameters:
- `{size}` (`integer`) Number of spaces.
- `{text}` (`string`) Text to indent.
- `{opts}` (`{ expandtab?: integer }?`)

Return (multiple):
(`string`) Indented text. (`integer`) Indent size before modification.

Lua module: vim.ui

vim.ui

vim.ui.input({opts}, {on_confirm}) vim.ui.input()

Prompts the user for input, allowing arbitrary (potentially asynchronous) work until `on_confirm`.

Example:

```
local opts = { prompt = 'Enter value for shiftwidth: ', scope = 'buffer' }
vim.ui.input(opts, function(input)
    vim.o.shiftwidth = tonumber(input)
end)
```

Parameters:
- `{opts}` (`table?`) Additional options. See input()
  - `{completion}?` (`string`) Specifies type of completion supported for input. Supported types are the same that can be supplied to a user-defined command using the "-complete=" argument. See :command-completion
  - `{default}?` (`string`) Default reply to the input
  - `{highlight}?` (`function`) Function that will be used for highlighting user inputs.
  - `{prompt}?` (`string`) Text of the prompt
  - `{scope}?` (`'cursor'|'line'|'buffer'|'window'|'tabpage'|'editor'|'project'`) Input scope, as in "This input is for something at cursor/line/etc scope". Can be used by `vim.ui.input` implementations to tweak behavior and presentation. For example, the input may adjust the floating window position: near the cursor if `cursor`, in window corner if `buffer` or `window`, etc.
- `{on_confirm}` (`fun(input?: string)`) Called once the user confirms or abort the input. `input` is what the user typed (it might be an empty string if nothing was entered), or `nil` if the user aborted the dialog.

vim.ui.open({path}, {opt}) vim.ui.open()

Opens `path` with the system default handler (macOS `open`, Windows `explorer.exe`, Linux `xdg-open`, …), or returns (but does not show) an error message on failure.

Can also be invoked with `:Open`. :Open

Expands "~/" and environment variables in filesystem paths.

Examples:

```
-- Asynchronous.
vim.ui.open("https://neovim.io/")
vim.ui.open("~/path/to/file")
-- Use the "osurl" command to handle the path or URL.
vim.ui.open("gh#neovim/neovim!29490", { cmd = { 'osurl' } })
-- Synchronous (wait until the process exits).
local cmd, err = vim.ui.open("$VIMRUNTIME")
if cmd then
  cmd:wait()
end
```

Parameters:
- `{path}` (`string`) Path or URL to open
- `{opt}` (`table?`) Options
  - `{cmd}?` (`string[]`) Command used to open the path or URL.

Return (multiple):
(`vim.SystemObj?`) Command object, or nil if not found. (`string?`) Error message on failure, or nil on success.

See also:
- vim.system()

vim.ui.progress_status() vim.ui.progress_status()
Gets a status description summarizing currently running progress messages. Convenient for inclusion in 'statusline'.

Return:
(`string`) Progress status

vim.ui.select({`items`}, {`opts`}, {`on_choice`}) vim.ui.select()
Prompts the user to pick from a list of items, allowing arbitrary (potentially asynchronous) work until `on_choice`. This is the standard "picker" interface, used by z=, :tselect, etc.

Plugins may override `vim.ui.select` to provide a custom picker; they are expected to call the `format_item` and `preview_item` handlers (if any) provided by the caller. They may also use the `kind` hint (if provided by the caller) to decide how to handle some items.

Note: the default `vim.ui.select` currently doesn't support preview.

Example:

```
vim.ui.select({ 'tabs', 'spaces' }, {
  prompt = 'Select tabs or spaces:',
  format_item = function(item)
    return ('I choose %s!'):format(item)
  end,
  preview_item = function(item)
    local lines = { 'This is ' .. vim.inspect(item) }
    local buf = vim.api.nvim_create_buf(false, true)
    vim.api.nvim_buf_set_lines(buf, 0, -1, false, lines)
    vim.bo[buf].bufhidden = 'wipe'
    return { buf = buf }
  end,
}, function(choice)
  vim.o.expandtab = choice == 'spaces'
  vim.print(('Selected "%s" => expandtab=%s'):format(choice, vim.o.expandtab))
end)
```

Parameters:
- {`items`} (`any[]`) Arbitrary items
- {`opts`} (`table`) Options
  - {`format_item`}? (`fun(item: any):string`, default: `tostring`) Decides how to format items when displayed in the picker.
  - {`kind`}? (`string`) Arbitrary hint string indicating the item shape. The picker may wish to use this to infer the structure or semantics of `items`, or the context in which select() was called.
  - {`preview_item`}? (`fun(item: any):{buf?:integer, pos?:[integer,integer], pos_end?:[integer,integer]}`) Decides how to preview an item by preparing a scratch buffer with the item details (including text, highlighting, etc.). When the picker decides to "preview" an item, it should call this function. Must return a table with these keys:
    - {`buf`}? (`integer`) Buffer containing the previewed item details, or nil if no preview should be shown.
    - {`pos`}? (`[integer, integer]`) Specifies the (1,0)-indexed cursor position in the preview buffer. If nil, should be treated as `{ 1, 0 }`.
    - {`pos_end`}? (`[integer, integer]`) Specifies the (1,0)-indexed (end-exclusive) end position of the preview range. If nil, no range is intended for a preview.
  - {`prompt`}? (`string`, default: `"Select one of:"`) Prompt text.
- {`on_choice`} (`fun(item: T?, idx: integer?)`) Called once the user made a choice. `idx` is the 1-based index of `item` within `items`, or `nil` if the user aborted the dialog.

Lua module: vim.ui.img vim.ui.img

EXPERIMENTAL: This API may change in the future. Its semantics are not yet finalized.

This provides a functional API for displaying images in Nvim. Currently supports PNG images via the Kitty graphics protocol.

To override the image backend, replace `vim.ui.img` with your own implementation providing set/get/del.

Examples:

```
-- Load image bytes from disk and display at row 5, column 10
local id = vim.ui.img.set(
 vim.fn.readblob('/path/to/img.png'),
 { row = 5, col = 10, width = 40, height = 20, zindex = 50 }
)

-- Update the image position
vim.ui.img.set(id, { row = 8, col = 12 })

-- Retrieve the current image opts
local opts = vim.ui.img.get(id)

-- Remove the image
vim.ui.img.del(id)

-- Remove all images
vim.ui.img.del(math.huge)
```

vim.ui.img.del({`id`}) vim.ui.img.del()
Delete an image, or all images if `math.huge` is given as the id.

Parameters:
- {`id`} (`integer`) image id, or `math.huge` to delete all images

Return:
(`boolean`) found true if any image existed

vim.ui.img.get({id}) vim.ui.img.get()
Get the opts for an image.

Parameters:
- {id} (integer)

Return:
(table?) opts copy of image opts, or nil if not found
- {col}? (integer) starting column (1-indexed)
- {height}? (integer) height in cells
- {row}? (integer) starting row (1-indexed)
- {width}? (integer) width in cells
- {zindex}? (integer) stacking order (higher = on top)

vim.ui.img.set({data_or_id}, {opts}) vim.ui.img.set()
Display an image or update an existing one.

When {data_or_id} is a string, displays the image bytes at the position given by {opts}. Returns an integer id for later use.

When {data_or_id} is an integer (a previously returned id), updates the image with new {opts}.

Parameters:
- {data_or_id} (string|integer) image bytes (string) or existing id (integer)
- {opts} (table?) A table with the following fields:
  - {col}? (integer) starting column (1-indexed)
  - {height}? (integer) height in cells
  - {row}? (integer) starting row (1-indexed)
  - {width}? (integer) width in cells
  - {zindex}? (integer) stacking order (higher = on top)

Return:
(integer) id

Lua module: vim.uri vim.uri

vim.uri_decode({str}) vim.uri_decode()
URI-decodes a string containing percent escapes.

Parameters:
- {str} (string) string to decode

Return:
(string) decoded string

vim.uri_encode({str}, {rfc}) vim.uri_encode()
URI-encodes a string using percent escapes.

Parameters:
- {str} (string) string to encode
- {rfc} ("rfc2396"|"rfc2732"|"rfc3986"?)

Return:
(string) encoded string

vim.uri_from_bufnr({buf}) vim.uri_from_bufnr()
Gets a URI from a bufnr.

Parameters:
- {buf} (integer)

Return:
(string) URI

vim.uri_from_fname({path}) vim.uri_from_fname()
Gets a URI from a file path.

Parameters:
- {path} (string) Path to file

Return:
(string) URI

vim.uri_to_bufnr({uri}) vim.uri_to_bufnr()
Gets the buffer for a uri. Creates a new unloaded buffer if no buffer for the uri already exists.

Parameters:
- {uri} (string)

Return:
(integer) bufnr

vim.uri_to_fname({uri}) vim.uri_to_fname()
Gets a filename from a URI.

Parameters:
- {uri} (string)

Return:
(string) filename or unchanged URI for non-file URIs

Lua module: vim.version

vim.version

The `vim.version` module provides functions for comparing versions and ranges conforming to the https://semver.org spec. Plugins, and plugin managers, can use this to check available tools and dependencies on the current system.

Example:

```
local v = vim.version.parse(vim.system({'tmux', '-V'}):wait().stdout, {strict=false})
if vim.version.gt(v, {3, 2, 0}) then
  -- ...
end
```

vim.version() returns the version of the current Nvim process.

VERSION RANGE SPEC

version-range

A version "range spec" defines a semantic version range which can be tested against a version, using vim.version.range().

Supported range specs are shown in the following table. **Note:** suffixed versions (1.2.3-rc1) are not matched.

```
1.2.3            is 1.2.3
=1.2.3           is 1.2.3
>1.2.3           greater than 1.2.3
<1.2.3           before 1.2.3
>=1.2.3          at least 1.2.3
<=1.2.3          at most 1.2.3
~1.2.3           is >=1.2.3 <1.3.0       "reasonably close to 1.2.3"
^1.2.3           is >=1.2.3 <2.0.0       "compatible with 1.2.3"
^0.2.3           is >=0.2.3 <0.3.0       (0.x.x is special)
^0.0.1           is =0.0.1               (0.0.x is special)
^1.2             is >=1.2.0 <2.0.0       (like ^1.2.0)
~1.2             is >=1.2.0 <1.3.0       (like ~1.2.0)
^1               is >=1.0.0 <2.0.0       "compatible with 1"
~1               same                    "reasonably close to 1"
1.x              same
1.*              same
1                same
*                any version
x                same

1.2.3 - 2.3.4    is >=1.2.3 <2.3.4

Partial right: missing pieces treated as x (2.3 => 2.3.x).
1.2.3 - 2.3      is >=1.2.3 <2.4.0
1.2.3 - 2        is >=1.2.3 <3.0.0

Partial left: missing pieces treated as 0 (1.2 => 1.2.0).
1.2 - 2.3.0      is 1.2.0 - 2.3.0
```

vim.VersionRange

Fields:

- {from} (vim.Version)
- {has} (fun(self: vim.VersionRange, version: string|vim.Version): boolean) See VersionRange:has().
- {to}? (vim.Version)

VersionRange:has({version})

VersionRange:has()

Check if a version is in the range (inclusive `from`, exclusive `to`).

Example:

```
local r = vim.version.range('1.0.0 - 2.0.0')
print(r:has('1.9.9'))       -- true
print(r:has('2.0.0'))       -- false
print(r:has(vim.version())) -- check against current Nvim version
```

Or use cmp(), le(), lt(), ge(), gt(), and/or eq() to compare a version against `.to` and `.from` directly:

```
local r = vim.version.range('1.0.0 - 2.0.0') -- >=1.0, <2.0
print(vim.version.ge({1,0,3}, r.from) and vim.version.lt({1,0,3}, r.to))
```

Attributes:
Since: 0.9.0

Parameters:

- {version} (string|vim.Version)

Return:
(boolean)

See also:

- https://github.com/npm/node-semver#ranges

vim.version()

vim.version()

Returns the current Nvim version.

Return:
(vim.Version)

vim.version.cmp({v1}, {v2}) vim.version.cmp()
Parses and compares two version objects (the result of vim.version.parse(), or specified literally as a `{major, minor, patch}` tuple, e.g. `{1, 0, 3}`).

Example:

```
if vim.version.cmp({1,0,3}, {0,2,1}) == 0 then
  -- ...
end
local v1 = vim.version.parse('1.0.3-pre')
local v2 = vim.version.parse('0.2.1')
if vim.version.cmp(v1, v2) == 0 then
  -- ...
end
```

Note:
- Per semver, build metadata is ignored when comparing two otherwise-equivalent versions.

Attributes:
Since: 0.9.0

Parameters:
- `{v1}` (`vim.Version|number[]|string`) Version object.
- `{v2}` (`vim.Version|number[]|string`) Version to compare with v1.

Return:
(`integer`) -1 if `v1 < v2`, 0 if `v1 == v2`, 1 if `v1 > v2`.

vim.version.eq({v1}, {v2}) vim.version.eq()
Returns `true` if the given versions are equal. See vim.version.cmp() for usage.

Attributes:
Since: 0.9.0

Parameters:
- `{v1}` (`vim.Version|number[]|string`)
- `{v2}` (`vim.Version|number[]|string`)

Return:
(`boolean`)

vim.version.ge({v1}, {v2}) vim.version.ge()
Returns `true` if `v1 >= v2`. See vim.version.cmp() for usage.

Attributes:
Since: 0.10.0

Parameters:
- `{v1}` (`vim.Version|number[]|string`)
- `{v2}` (`vim.Version|number[]|string`)

Return:
(`boolean`)

vim.version.gt({v1}, {v2}) vim.version.gt()
Returns `true` if `v1 > v2`. See vim.version.cmp() for usage.

Attributes:
Since: 0.9.0

Parameters:
- `{v1}` (`vim.Version|number[]|string`)
- `{v2}` (`vim.Version|number[]|string`)

Return:
(`boolean`)

vim.version.intersect({r1}, {r2}) vim.version.intersect()
Computes the common range shared by the given ranges.

Attributes:
Since: 0.12.0

Parameters:
- `{r1}` (`vim.VersionRange`) First range to intersect.
- `{r2}` (`vim.VersionRange`) Second range to intersect.

Return:
(`vim.VersionRange?`) Maximal range that is present inside both `r1` and `r2`. `nil` if such range does not exist.

vim.version.last({versions}) vim.version.last()
TODO: generalize this, move to func.lua

Parameters:
- `{versions}` (`vim.Version[]`)

Return:
(`vim.Version?`)

vim.version.le({v1}, {v2}) vim.version.le()
Returns `true` if `v1 <= v2`. See vim.version.cmp() for usage.

Attributes:
Since: 0.10.0

Parameters:
- {v1} (vim.Version|number[]|string)
- {v2} (vim.Version|number[]|string)

Return:
(boolean)

vim.version.lt({v1}, {v2}) vim.version.lt()
Returns true if v1 < v2. See vim.version.cmp() for usage.

Attributes:
Since: 0.9.0

Parameters:
- {v1} (vim.Version|number[]|string)
- {v2} (vim.Version|number[]|string)

Return:
(boolean)

vim.version.parse({version}, {opts}) vim.version.parse()
Parses a semantic version string and returns a version object which can be used with other vim.version functions. For example "1.0.1-rc1+build.2" returns:

```
{ major = 1, minor = 0, patch = 1, prerelease = "rc1", build = "build.2" }
```

Attributes:
Since: 0.9.0

Parameters:
- {version} (string) Version string to parse.
- {opts} (table?) Options for parsing.
  - {strict}? (boolean, default: false) If true, no coercion is attempted on input not conforming to semver v2.0.0. If false, parse() attempts to coerce input such as "1.0", "0-x", "tmux 3.2a" into valid versions.

Return:
(vim.Version?) Version object or nil if input is invalid.

See also:
- https://semver.org/spec/v2.0.0.html

vim.version.range({spec}) vim.version.range()
Parses a semver version-range "spec" and returns vim.VersionRange object:

Attributes:
Since: 0.9.0

Parameters:
- {spec} (string) Version range "spec"

Return:
(vim.VersionRange?)

UI2 ui2

WARNING: This is an experimental feature intended to replace the builtin message + cmdline presentation layer.

To enable this feature (default opts shown, see also 'messagesopt'):

```
require('vim._core.ui2').enable({
  enable = true, -- Whether to enable or disable the UI.
  msg = { -- Options related to the message module.
    ---@type string|table<string, 'cmd'|'msg'|'pager'> Default message target
    ---or table mapping |ui-messages| kinds, triggers and IDs to a target.
    ---Table keys are matched as a Lua pattern to the message ID. 'default'
    ---mapping applies to any omitted kind: { default = 'cmd', progress = 'msg' }.
    targets = 'cmd',
    dialog = { -- Options related to dialog window.
      height = 0.5, -- Maximum height.
    },
    msg = { -- Options related to msg window.
      height = 0.5, -- Maximum height.
    },
    pager = { -- Options related to message window.
      height = 0.999, -- Maximum height.
    },
  },
})
```

ui2 behavior is also configured by these 'messagesopt' items: "pager", "timeout". Example:

```
set messagesopt+=maxheight:50,pager:<CR>,timeout:4000
```

There are four special windows/buffers for presenting messages and cmdline:
- "cmd": Cmdline. Also used by default for messages, 'showcmd', 'showmode', 'ruler'.
- "msg": Message window. Shows ephemeral messages; useful if 'cmdheight' is 0.

- "pager": Pager window. Shows :messages, allows navigating all messages.
- "dialog": Dialog window. Shows modal prompts that wait for user input.

In each of the special buffers, 'filetype' is set as listed above ("cmd", "msg", ...). Handle the FileType event to configure any local options for these windows/buffers.

Unlike the legacy hit-enter prompt, messages exceeding 'cmdheight' are collapsed, followed by a `[+x]` "spill" indicator, where x is number of overflow lines. To see all messages, do either:
- g< at any time.
- Type the "pager" char (if configured in 'messagesopt'), immediately after an interactive : command.

LUA REFERENCE MANUAL

Version 0.3.0 August 7th, 2022

Vimdoc version (c) 2006 by Luis Carvalho <lexcarvalho at gmail dot com>

Adapted from "Lua: 5.1 reference manual" R. Ierusalimschy, L. H. de Figueiredo, W. Celes Copyright (c) 2006 Lua.org, PUC-Rio.

See lua-ref-doc for information on this manual. See lua-ref-copyright for copyright and licenses.

1 INTRODUCTION luaref-intro

Lua is an extension programming language designed to support general procedural programming with data description facilities. It also offers good support for object-oriented programming, functional programming, and data-driven programming. Lua is intended to be used as a powerful, light-weight scripting language for any program that needs one. Lua is implemented as a library, written in clean C (that is, in the common subset of ANSI C and C++).

Being an extension language, Lua has no notion of a "main" program: it only works embedded in a host client, called the embedding program or simply the host. This host program can invoke functions to execute a piece of Lua code, can write and read Lua variables, and can register C functions to be called by Lua code. Through the use of C functions, Lua can be augmented to cope with a wide range of different domains, thus creating customized programming languages sharing a syntactical framework.

Lua is free software, and is provided as usual with no guarantees, as stated in its license. The implementation described in this manual is available at Lua's official web site, www.lua.org.

Like any other reference manual, this document is dry in places. For a discussion of the decisions behind the design of Lua, see references at lua-ref-bibliography. For a detailed introduction to programming in Lua, see Roberto's book, Programming in Lua.

Lua means "moon" in Portuguese and is pronounced LOO-ah.

2 THE LANGUAGE lua-language

This section describes the lexis, the syntax, and the semantics of Lua. In other words, this section describes which tokens are valid, how they can be combined, and what their combinations mean.

The language constructs will be explained using the usual extended BNF notation, in which `{ a }` means 0 or more a's, and `[ a ]` means an optional a.

2.1 Lexical Conventions lua-lexical

lua-names lua-identifiers Names (also called identifiers) in Lua can be any string of letters, digits, and underscores, not beginning with a digit. This coincides with the definition of identifiers in most languages. (The definition of letter depends on the current locale: any character considered alphabetic by the current locale can be used in an identifier.) Identifiers are used to name variables and table fields.

The following keywords are reserved and cannot be used as names:

```
and       break     do        else      elseif
end       false     for       function  if
in        local     nil       not       or
repeat    return    then      true      until     while
```

Lua is a case-sensitive language: `and` is a reserved word, but `And` and `AND` are two different, valid names. As a convention, names starting with an underscore followed by uppercase letters (such as `_VERSION`) are reserved for internal global variables used by Lua.

The following strings denote other tokens:

```
+     -     *     /     %     ^     #
==    ~=    <=    >=    <     >     =
(     )     {     }     [     ]
;     :     ,     .     ..    ...
```

lua-literal

Literal strings can be delimited by matching single or double quotes, and can contain the following C-like escape sequences:

- `\a` bell
- `\b` backspace
- `\f` form feed
- `\n` newline
- `\r` carriage return
- `\t` horizontal tab
- `\v` vertical tab
- `\\` backslash
- `\"` quotation mark (double quote)
- `\'` apostrophe (single quote)

Moreover, a backslash followed by a real newline results in a newline in the string. A character in a string may also be specified by its numerical value using the escape sequence `\ddd`, where ddd is a sequence of up to three decimal digits. (Note that if a numerical escape is to be followed by a digit, it must be expressed using exactly three digits.) Strings in Lua may contain any 8-bit value, including embedded zeros, which can be specified as `\0`.

To put a double (single) quote, a newline, a backslash, or an embedded zero inside a literal string enclosed by double (single) quotes you must use an escape sequence. Any other character may be directly inserted into the literal. (Some control characters may cause problems for the file system, but Lua has no problem with them.)

Literal strings can also be defined using a long format enclosed by long brackets. We define an opening long bracket of level n as an opening square bracket followed by n equal signs followed by another opening square bracket. So, an opening long bracket of level 0 is written as `[[`,

an opening long bracket of level 1 is written as `[=[`, and so on. A closing long bracket is defined similarly; for instance, a closing long bracket of level 4 is written as `]====]`. A long string starts with an opening long bracket of any level and ends at the first closing long bracket of the same level. Literals in this bracketed form may run for several lines, do not interpret any escape sequences, and ignore long brackets of any other level. They may contain anything except a closing bracket of the proper level.

For convenience, when the opening long bracket is immediately followed by a newline, the newline is not included in the string. As an example, in a system using ASCII (in which a is coded as 97, newline is coded as 10, and 1 is coded as 49), the five literals below denote the same string:

```
a = 'alo\n123"'
a = "alo\n123\""
a = '\97lo\10\04923"'
a = [[alo
123"]]
a = [==[
alo
123"]==]
```

lua-numconstant

A numerical constant may be written with an optional decimal part and an optional decimal exponent. Lua also accepts integer hexadecimal constants, by prefixing them with `0x`. Examples of valid numerical constants are

```
3     3.0     3.1416  314.16e-2   0.31416E1   0xff   0x56
```

lua-comment

A comment starts with a double hyphen (`--`) anywhere outside a string. If the text immediately after `--` is not an opening long bracket, the comment is a short comment, which runs until the end of the line. Otherwise, it is a long comment, which runs until the corresponding closing long bracket. Long comments are frequently used to disable code temporarily.

2.2 Values and Types

lua-values

Lua is a dynamically typed language. This means that variables do not have types; only values do. There are no type definitions in the language. All values carry their own type.

All values in Lua are first-class values. This means that all values can be stored in variables, passed as arguments to other functions, and returned as results.

lua-types lua-nil lua-true lua-false lua-number lua-string There are eight basic types in Lua: `nil`, `boolean`, `number`, `string`, `function`, `userdata`, `thread`, and `table`. Nil is the type of the value `nil`, whose main property is to be different from any other value; it usually represents the absence of a useful value. Boolean is the type of the values `false` and `true`. Both `nil` and `false` make a condition false; any other value makes it true. Number represents real (double-precision floating-point) numbers. (It is easy to build Lua interpreters that use other internal representations for numbers, such as single-precision float or long integers; see file `luaconf.h`.) String represents arrays of characters. Lua is 8-bit clean: strings may contain any 8-bit character, including embedded zeros (`\0`) (see lua-literal).

Lua can call (and manipulate) functions written in Lua and functions written in C (see lua-function).

lua-userdatatype

The type userdata is provided to allow arbitrary C data to be stored in Lua variables. This type corresponds to a block of raw memory and has no pre-defined operations in Lua, except assignment and identity test. However, by using metatables, the programmer can define operations for userdata values (see lua-metatable). Userdata values cannot be created or modified in Lua, only through the C API. This guarantees the integrity of data owned by the host program.

lua-thread

The type `thread` represents independent threads of execution and it is used to implement coroutines (see lua-coroutine). Do not confuse Lua threads with operating-system threads. Lua supports coroutines on all systems, even those that do not support threads.

lua-table

The type `table` implements associative arrays, that is, arrays that can be indexed not only with numbers, but with any value (except `nil`). Tables can be heterogeneous; that is, they can contain values of all types (except `nil`). Tables are the sole data structuring mechanism in Lua; they may be used to represent ordinary arrays, symbol tables, sets, records, graphs, trees, etc. To represent records, Lua uses the field name as an index. The language supports this representation by providing `a.name` as syntactic sugar for `a["name"]`. There are several convenient ways to create tables in Lua (see lua-tableconstructor).

Like indices, the value of a table field can be of any type (except `nil`). In particular, because functions are first-class values, table fields may contain functions. Thus tables may also carry methods (see lua-function-define).

Tables, functions, threads and (full) userdata values are objects: variables do not actually contain these values, only references to them. Assignment, parameter passing, and function returns always manipulate references to such values; these operations do not imply any kind of copy.

The library function `type` returns a string describing the type of a given value (see lua-type()).

2.2.1 Coercion

lua-coercion

Lua provides automatic conversion between string and number values at run time. Any arithmetic operation applied to a string tries to convert that string to a number, following the usual conversion rules. Conversely, whenever a number is used where a string is expected, the number is converted to a string, in a reasonable format. For complete control of how numbers are converted to strings, use the `format` function from the string library (see string.format()).

2.3 Variables

lua-variables

Variables are places that store values. There are three kinds of variables in Lua: global variables, local variables, and table fields.

A single name can denote a global variable or a local variable (or a function's formal parameter, which is a particular form of local variable):

```
var ::= Name
```

Name denotes identifiers, as defined in lua-lexical.

Any variable is assumed to be global unless explicitly declared as a local (see lua-local). Local variables are lexically scoped: local variables can be freely accessed by functions defined inside their scope (see lua-visibility).

Before the first assignment to a variable, its value is `nil`.

Square brackets are used to index a table:

```
var ::= prefixexp [ exp ]
```

The first expression (`prefixexp`) should result in a table value; the second expression (`exp`) identifies a specific entry inside that table. The expression denoting the table to be indexed has a restricted syntax; see lua-expressions for details.

The syntax `var.NAME` is just syntactic sugar for `var["NAME"]` :

```
var ::= prefixexp . Name
```

All global variables live as fields in ordinary Lua tables, called environment tables or simply environments (see lua-environments). Each function has its own reference to an environment, so that all global variables in this function will refer to this environment table. When a function is created, it inherits the environment from the function that created it. To get the environment table of a Lua function, you call `getfenv` (see lua_getfenv()). To replace it, you call `setfenv` (see setfenv()). (You can only manipulate the environment of C functions through the debug library; see lua-lib-debug.)

An access to a global variable `x` is equivalent to `_env.x`, which in turn is equivalent to

```
gettable_event(_env, "x")
```

where _env is the environment of the running function. (The _env variable is not defined in Lua. We use it here only for explanatory purposes.)

The meaning of accesses to global variables and table fields can be changed via metatables. An access to an indexed variable `t[i]` is equivalent to a call `gettable_event(t,i)`. (See lua-metatable for a complete description of the `gettable_event` function. This function is not defined or callable in Lua. We use it here only for explanatory purposes.)

2.4 Statements **lua-statement**

Lua supports an almost conventional set of statements, similar to those in Pascal or C. This set includes assignment, control structures, function calls, and variable declarations.

2.4.1 Chunks **lua-chunk**

The unit of execution of Lua is called a chunk. A chunk is simply a sequence of statements, which are executed sequentially. Each statement can be optionally followed by a semicolon:

```
chunk ::= {stat [ ; ]}
```

There are no empty statements and thus `;;` is not legal.

Lua handles a chunk as the body of an anonymous function with a variable number of arguments (see lua-function-define). As such, chunks can define local variables, receive arguments, and return values.

A chunk may be stored in a file or in a string inside the host program. When a chunk is executed, first it is pre-compiled into instructions for a virtual machine, and then the compiled code is executed by an interpreter for the virtual machine.

Chunks may also be pre-compiled into binary form; see program `luac` for details. Programs in source and compiled forms are interchangeable; Lua automatically detects the file type and acts accordingly.

2.4.2 Blocks **lua-block**

A block is a list of statements; syntactically, a block is the same as a chunk:

```
block ::= chunk
```

lua-do lua-end A block may be explicitly delimited to produce a single statement:

```
stat ::= do block end
```

Explicit blocks are useful to control the scope of variable declarations. Explicit blocks are also sometimes used to add a `return` or `break` statement in the middle of another block (see lua-control).

2.4.3 Assignment **lua-assign**

Lua allows multiple assignment. Therefore, the syntax for assignment defines a list of variables on the left side and a list of expressions on the right side. The elements in both lists are separated by commas:

```
stat ::= varlist1 = explist1
varlist1 ::= var { , var }
explist1 ::= exp { , exp }
```

Expressions are discussed in lua-expressions.

Before the assignment, the list of values is adjusted to the length of the list of variables. If there are more values than needed, the excess values are thrown away. If there are fewer values than needed, the list is extended with as many `nils` as needed. If the list of expressions

ends with a function call, then all values returned by this call enter in the list of values, before the adjustment (except when the call is enclosed in parentheses; see lua-expressions).

The assignment statement first evaluates all its expressions and only then are the assignments performed. Thus the code

```
i = 3
i, a[i] = i+1, 20
```

sets a[3] to 20, without affecting a[4] because the i in a[i] is evaluated (to 3) before it is assigned 4. Similarly, the line

```
x, y = y, x
```

exchanges the values of x and y.

The meaning of assignments to global variables and table fields can be changed via metatables. An assignment to an indexed variable t[i] = val is equivalent to settable_event(t,i,val). (See lua-metatable for a complete description of the settable_event function. This function is not defined or callable in Lua. We use it here only for explanatory purposes.)

An assignment to a global variable x = val is equivalent to the assignment _env.x = val, which in turn is equivalent to

```
settable_event(_env, "x", val)
```

where _env is the environment of the running function. (The _env variable is not defined in Lua. We use it here only for explanatory purposes.)

2.4.4 Control Structures

lua-control

lua-if lua-then lua-else lua-elseif lua-while lua-repeat lua-until The control structures if, while, and repeat have the usual meaning and familiar syntax:

```
stat ::=  while  exp do block end
stat ::=  repeat  block until exp
stat ::=  if  exp then block { elseif exp then block }
          [ else block ] end
```

Lua also has a for statement, in two flavors (see lua-for).

The condition expression of a control structure may return any value. Both false and nil are considered false. All values different from nil and false are considered true (in particular, the number 0 and the empty string are also true).

In the repeat-until loop, the inner block does not end at the until keyword, but only after the condition. So, the condition can refer to local variables declared inside the loop block.

lua-return

The return statement is used to return values from a function or a chunk (which is just a function). Functions and chunks may return more than one value, so the syntax for the return statement is

stat ::= return [explist1]

lua-break

The break statement is used to terminate the execution of a while, repeat, or for loop, skipping to the next statement after the loop:

stat ::= break

A break ends the innermost enclosing loop.

The return and break statements can only be written as the last statement of a block. If it is really necessary to return or break in the middle of a block, then an explicit inner block can be used, as in the idioms do return end and do break end, because now return and break are the last statements in their (inner) blocks.

2.4.5 For Statement

for lua-for

The for statement has two forms: one numeric and one generic.

The numeric for loop repeats a block of code while a control variable runs through an arithmetic progression. It has the following syntax:

```
stat ::=  for  Name = exp , exp [ , exp ] do block end
```

The block is repeated for name starting at the value of the first exp, until it passes the second exp by steps of the third exp. More precisely, a for statement like

for var = e1, e2, e3 do block end

is equivalent to the code:

```
do
  local  var, limit, step  = tonumber(e1), tonumber(e2), tonumber(e3)
  if not (  var  and  limit  and  step  ) then error() end
  while (  step  >0 and  var  <=  limit  )
          or (  step  <=0 and  var  >=  limit  ) do
     block
     var  =  var  +  step
  end
end
```

Note the following:

- All three control expressions are evaluated only once, before the loop starts. They must all result in numbers.
- var, limit and step are invisible variables. The names are here for explanatory purposes only.
- If the third expression (the step) is absent, then a step of 1 is used.

- You can use `break` to exit a `for` loop.
- The loop variable `var` is local to the loop; you cannot use its value after the `for` ends or is broken. If you need this value, assign it to another variable before breaking or exiting the loop.

for-in

The generic `for` statement works over functions, called iterators. On each iteration, the iterator function is called to produce a new value, stopping when this new value is `nil`. The generic `for` loop has the following syntax:

```
stat ::=  for  namelist in explist1 do block end
namelist ::= Name { , Name }
```

A `for` statement like

`for var1, ..., varn in explist do block end`

is equivalent to the code:

```
do
  local  f, s, var  =  explist
  while true do
      local  var1, ..., varn  =  f(s, var)
      var  =  var1
      if  var  == nil then break end
      block
  end
end
```

Note the following:

- `explist` is evaluated only once. Its results are an iterator function, a `state`, and an initial value for the first iterator variable.
- `f`, `s`, and `var` are invisible variables. The names are here for explanatory purposes only.
- You can use `break` to exit a `for` loop.
- The loop variables `var1, ..., varn` are local to the loop; you cannot use their values after the `for` ends. If you need these values, then assign them to other variables before breaking or exiting the loop.

2.4.6 Function Calls as Statements

lua-funcstatement

To allow possible side-effects, function calls can be executed as statements:

```
stat ::= functioncall
```

In this case, all returned values are thrown away. Function calls are explained in lua-function.

2.4.7 Local Declarations

lua-local

Local variables may be declared anywhere inside a block. The declaration may include an initial assignment:

```
stat ::=  local  namelist [ = explist1 ]
namelist ::= Name { , Name }
```

If present, an initial assignment has the same semantics of a multiple assignment (see lua-assign). Otherwise, all variables are initialized with `nil`.

A chunk is also a block (see lua-chunk), and so local variables can be declared in a chunk outside any explicit block. The scope of such local variables extends until the end of the chunk.

The visibility rules for local variables are explained in lua-visibility.

2.5 Expressions

lua-expressions

The basic expressions in Lua are the following:

```
exp ::= prefixexp
exp ::=  nil  |  false  |  true
exp ::= Number
exp ::= String
exp ::= function
exp ::= tableconstructor
exp ::= ...
exp ::= exp binop exp
exp ::= unop exp
prefixexp ::= var | functioncall | ( exp )
```

Numbers and literal strings are explained in lua-lexical; variables are explained in lua-variables; function definitions are explained in lua-function-define; function calls are explained in lua-function; table constructors are explained in lua-tableconstructor. Vararg expressions, denoted by three dots (`...`), can only be used inside vararg functions; they are explained in lua-function-define.

Binary operators comprise arithmetic operators (see lua-arithmetic), relational operators (see lua-relational), logical operators (see lua-logicalop), and the concatenation operator (see lua-concat). Unary operators comprise the unary minus (see lua-arithmetic), the unary `not` (see lua-logicalop), and the unary length operator (see lua-length).

Both function calls and vararg expressions may result in multiple values. If the expression is used as a statement (see lua-funcstatement) (only possible for function calls), then its return list is adjusted to zero elements, thus discarding all returned values. If the expression is used as the last (or the only) element of a list of expressions, then no adjustment is made (unless the call is enclosed in parentheses). In all other contexts, Lua adjusts the result list to one element, discarding all values except the first one.

Here are some examples:

```
f()                -- adjusted to 0 results
g(f(), x)          -- f() is adjusted to 1 result
g(x, f())          -- g gets x plus all results from f()
a,b,c = f(), x     -- f() is adjusted to 1 result (c gets nil)
a,b = ...          -- a gets the first vararg parameter, b gets
                   -- the second (both a and b may get nil if there
                   -- is no corresponding vararg parameter)

a,b,c = x, f()     -- f() is adjusted to 2 results
a,b,c = f()        -- f() is adjusted to 3 results
return f()         -- returns all results from f()
return ...         -- returns all received vararg parameters
return x,y,f()     -- returns x, y, and all results from f()
{f()}              -- creates a list with all results from f()
{...}              -- creates a list with all vararg parameters
{f(), nil}         -- f() is adjusted to 1 result
```

An expression enclosed in parentheses always results in only one value. Thus, `(f(x,y,z))` is always a single value, even if `f` returns several values. (The value of `(f(x,y,z))` is the first value returned by `f` or `nil` if `f` does not return any values.)

2.5.1 Arithmetic Operators

lua-arithmetic

Lua supports the usual arithmetic operators: the binary + (addition), - (subtraction), * (multiplication), / (division), % (modulo) and ^ (exponentiation); and unary - (negation). If the operands are numbers, or strings that can be converted to numbers (see lua-coercion), then all operations have the usual meaning. Exponentiation works for any exponent. For instance, `x^(-0.5)` computes the inverse of the square root of x. Modulo is defined as

```
a % b == a - math.floor(a/b)*b
```

That is, it is the remainder of a division that rounds the quotient towards minus infinity.

2.5.2 Relational Operators

lua-relational

The relational operators in Lua are

```
==    ~=    <     >     <=    >=
```

These operators always result in `false` or `true`.

Equality (==) first compares the type of its operands. If the types are different, then the result is `false`. Otherwise, the values of the operands are compared. Numbers and strings are compared in the usual way. Objects (tables, userdata, threads, and functions) are compared by reference: two objects are considered equal only if they are the same object. Every time you create a new object (a table, userdata, or function), this new object is different from any previously existing object.

You can change the way that Lua compares tables and userdata using the "eq" metamethod (see lua-metatable).

The conversion rules of coercion lua-coercion do not apply to equality comparisons. Thus, `"0"==0` evaluates to `false`, and `t[0]` and `t["0"]` denote different entries in a table.

The operator ~= is exactly the negation of equality (==).

The order operators work as follows. If both arguments are numbers, then they are compared as such. Otherwise, if both arguments are strings, then their values are compared according to the current locale. Otherwise, Lua tries to call the "lt" or the "le" metamethod (see lua-metatable).

2.5.3 Logical Operators

lua-logicalop

The logical operators in Lua are

```
and    or    not
```

Like the control structures (see lua-control), all logical operators consider both `false` and `nil` as false and anything else as true.

lua-not lua-and lua-or The negation operator `not` always returns `false` or `true`. The conjunction operator `and` returns its first argument if this value is `false` or `nil`; otherwise, and returns its second argument. The disjunction operator `or` returns its first argument if this value is different from `nil` and `false`; otherwise, `or` returns its second argument. Both `and` and `or` use short-cut evaluation, that is, the second operand is evaluated only if necessary. Here are some examples:

```
10 or 20            --> 10
10 or error()       --> 10
nil or "a"          --> "a"
nil and 10          --> nil
false and error()   --> false
false and nil       --> false
false or nil        --> nil
10 and 20           --> 20
```

(In this manual, `-->` indicates the result of the preceding expression.)

2.5.4 Concatenation

lua-concat

The string concatenation operator in Lua is denoted by two dots (`..`). If both operands are strings or numbers, then they are converted to strings according to the rules mentioned in lua-coercion. Otherwise, the "concat" metamethod is called (see lua-metatable).

2.5.5 The Length Operator

lua-# lua-length

The length operator is denoted by the unary operator #. The length of a string is its number of bytes (that is, the usual meaning of string length when each character is one byte).

The length of a table `t` is defined to be any integer index `n` such that `t[n]` is not `nil` and `t[n+1]` is `nil`; moreover, if `t[1]` is `nil`, `n` may be zero. For a regular array, with non-nil values from 1 to a given `n`, its length is exactly that `n`, the index of its last value. If the array has "holes" (that is, `nil` values between other non-nil values), then `#t` may be any of the indices that directly precedes a `nil` value (that is, it may consider any such `nil` value as the end of the array).

2.5.6 Precedence

lua-precedence

Operator precedence in Lua follows the table below, from lower to higher priority:

```
or
and
<     >     <=    >=    ~=    ==
..
+     -
*     /
not   #     - (unary)
^
```

As usual, you can use parentheses to change the precedences in an expression. The concatenation (`..`) and exponentiation (^) operators are right associative. All other binary operators are left associative.

2.5.7 Table Constructors

lua-tableconstructor

Table constructors are expressions that create tables. Every time a constructor is evaluated, a new table is created. Constructors can be used to create empty tables, or to create a table and initialize some of its fields. The general syntax for constructors is

```
tableconstructor ::= { [ fieldlist ] }
fieldlist ::= field { fieldsep field } [ fieldsep ]
field ::= [ exp ]  = exp | Name = exp | exp
fieldsep ::=  , |  ;
```

Each field of the form `[exp1] = exp2` adds to the new table an entry with key `exp1` and value `exp2`. A field of the form `name = exp` is equivalent to `["name"] = exp`. Finally, fields of the form `exp` are equivalent to `[i] = exp`, where `i` are consecutive numerical integers, starting with 1. Fields in the other formats do not affect this counting. For example,

```
a = { [f(1)] = g; "x", "y"; x = 1, f(x), [30] = 23; 45 }
```

is equivalent to

```
do
  local t = {}
  t[f(1)] = g
  t[1] = "x"         -- 1st exp
  t[2] = "y"         -- 2nd exp
  t.x = 1            -- temp["x"] = 1
  t[3] = f(x)        -- 3rd exp
  t[30] = 23
  t[4] = 45          -- 4th exp
  a = t
end
```

If the last field in the list has the form exp and the expression is a function call, then all values returned by the call enter the list consecutively (see lua-function). To avoid this, enclose the function call in parentheses (see lua-expressions).

The field list may have an optional trailing separator, as a convenience for machine-generated code.

2.5.8 Function Calls

lua-function

A function call in Lua has the following syntax:

```
functioncall ::= prefixexp args
```

In a function call, first `prefixexp` and `args` are evaluated. If the value of `prefixexp` has type `function`, then this function is called with the given arguments. Otherwise, the `prefixexp` "call" metamethod is called, having as first parameter the value of `prefixexp`, followed by the original call arguments (see lua-metatable).

The form

```
functioncall ::= prefixexp : Name args
```

can be used to call "methods". A call `v:name( args )` is syntactic sugar for `v.name(v, args )`, except that v is evaluated only once.

Arguments have the following syntax:

```
args ::=  ( [ explist1 ] )
args ::= tableconstructor
args ::= String
```

All argument expressions are evaluated before the call. A call of the form `f{ fields }` is syntactic sugar for `f({ fields })`, that is, the argument list is a single new table. A call of the form `f' string '` (or `f" string "` or `f[[ string ]]`) is syntactic sugar for `f(' string ')`, that is, the argument list is a single literal string.

As an exception to the free-format syntax of Lua, you cannot put a line break before the `(` in a function call. This restriction avoids some ambiguities in the language. If you write

```
a = f
(g).x(a)
```

Lua would see that as a single statement, `a = f(g).x(a)`. So, if you want two statements, you must add a semi-colon between them. If you actually want to call `f`, you must remove the line break before `(g)`.

lua-tailcall

A call of the form `return functioncall` is called a tail call. Lua implements proper tail calls (or proper tail recursion): in a tail call, the called function reuses the stack entry of the calling function. Therefore, there is no limit on the number of nested tail calls that a program can execute. However, a tail call erases any debug information about the calling function. Note that a tail call only happens with a particular syntax, where the `return` has one single function call as argument; this syntax makes the calling function return exactly the returns of the called function. So, none of the following examples are tail calls:

```
return (f(x))        -- results adjusted to 1
return 2 * f(x)
return x, f(x)       -- additional results
f(x); return         -- results discarded
return x or f(x)     -- results adjusted to 1
```

2.5.9 Function Definitions

lua-function-define

The syntax for function definition is

```
function ::= function funcbody
funcbody ::= ( [ parlist1 ] ) block end
```

The following syntactic sugar simplifies function definitions:

```
stat ::= function funcname funcbody
stat ::= local function Name funcbody
funcname ::= Name { . Name } [ : Name ]
```

The statement

`function f () body end`

translates to

`f = function () body end`

The statement

`function t.a.b.c.f () body end`

translates to

`t.a.b.c.f = function () body end`

The statement

`local function f () body end`

translates to

`local f; f = function f () body end`

not to

`local f = function f () body end`

(This only makes a difference when the body of the function contains references to `f`.)

lua-closure

A function definition is an executable expression, whose value has type `function`. When Lua pre-compiles a chunk, all its function bodies are pre-compiled too. Then, whenever Lua executes the function definition, the function is instantiated (or closed). This function instance (or closure) is the final value of the expression. Different instances of the same function may refer to different external local variables and may have different environment tables.

Parameters act as local variables that are initialized with the argument values:

```
parlist1 ::= namelist [ , ... ] | ...
```

lua-vararg

When a function is called, the list of arguments is adjusted to the length of the list of parameters, unless the function is a variadic or vararg function, which is indicated by three dots (`...`) at the end of its parameter list. A vararg function does not adjust its argument list; instead, it collects all extra arguments and supplies them to the function through a vararg expression, which is also written as three dots. The value of this expression is a list of all actual extra arguments, similar to a function with multiple results. If a vararg expression is used inside another expression or in the middle of a list of expressions, then its return list is adjusted to one element. If the expression is used as the last element of a list of expressions, then no adjustment is made (unless the call is enclosed in parentheses).

As an example, consider the following definitions:

```
function f(a, b) end
function g(a, b, ...) end
function r() return 1,2,3 end
```

Then, we have the following mapping from arguments to parameters and to the vararg expression:

```
CALL            PARAMETERS

f(3)             a=3, b=nil
f(3, 4)          a=3, b=4
f(3, 4, 5)       a=3, b=4
f(r(), 10)       a=1, b=10
f(r())           a=1, b=2

g(3)             a=3, b=nil, ... -->  (nothing)
g(3, 4)          a=3, b=4,   ... -->  (nothing)
g(3, 4, 5, 8)    a=3, b=4,   ... -->  5  8
g(5, r())        a=5, b=1,   ... -->  2  3
```

Results are returned using the `return` statement (see lua-control). If control reaches the end of a function without encountering a `return` statement, then the function returns with no results.

lua-colonsyntax

The colon syntax is used for defining methods, that is, functions that have an implicit extra parameter `self`. Thus, the statement

`function t.a.b.c:f ( params ) body end`

is syntactic sugar for

`t.a.b.c:f = function ( self, params ) body end`

2.6 Visibility Rules **lua-visibility**

Lua is a lexically scoped language. The scope of variables begins at the first statement after their declaration and lasts until the end of the innermost block that includes the declaration. Consider the following example:

```
x = 10                -- global variable
do                    -- new block
  local x = x         -- new `x`, with value 10
  print(x)            --> 10
  x = x+1
  do                  -- another block
    local x = x+1     -- another `x`
    print(x)          --> 12
  end
  print(x)            --> 11
end
print(x)              --> 10  (the global one)
```

Notice that, in a declaration like `local x = x`, the new x being declared is not in scope yet, and so the second x refers to the outside variable.

lua-upvalue

Because of the lexical scoping rules, local variables can be freely accessed by functions defined inside their scope. A local variable used by an inner function is called an upvalue, or external local variable, inside the inner function.

Notice that each execution of a local statement defines new local variables. Consider the following example:

```
a = {}
local x = 20
for i=1,10 do
  local y = 0
  a[i] = function () y=y+1; return x+y end
end
```

The loop creates ten closures (that is, ten instances of the anonymous function). Each of these closures uses a different y variable, while all of them share the same x.

2.7 Error Handling **lua-errors**

Because Lua is an embedded extension language, all Lua actions start from C code in the host program calling a function from the Lua library (see lua_pcall()). Whenever an error occurs during Lua compilation or execution, control returns to C, which can take appropriate measures (such as print an error message).

Lua code can explicitly generate an error by calling the `error` function (see error()). If you need to catch errors in Lua, you can use the `pcall` function (see pcall()).

2.8 Metatables **metatable** **lua-metatable**

Every value in Lua may have a metatable. This metatable is an ordinary Lua table that defines the behavior of the original table and userdata under certain special operations. You can change several aspects of the behavior of an object by setting specific fields in its metatable. For instance, when a non-numeric value is the operand of an addition, Lua checks for a function in the field "__add" in its metatable. If it finds one, Lua calls that function to perform the addition.

We call the keys in a metatable events and the values metamethods. In the previous example, the event is "add" and the metamethod is the function that performs the addition.

You can query the metatable of any value through the `getmetatable` function (see getmetatable()).

You can replace the metatable of tables through the `setmetatable` function (see setmetatable()). You cannot change the metatable of other types from Lua (except using the debug library); you must use the C API for that.

Tables and userdata have individual metatables (although multiple tables and userdata can share a same table as their metatable); values of all other types share one single metatable per type. So, there is one single metatable for all numbers, and for all strings, etc.

A metatable may control how an object behaves in arithmetic operations, order comparisons, concatenation, length operation, and indexing. A metatable can also define a function to be called when a userdata is garbage collected. For each of those operations Lua associates a specific key called an event. When Lua performs one of those operations over a value, it checks whether this value has a metatable with the corresponding event. If so, the value associated with that key (the metamethod) controls how Lua will perform the operation.

Metatables control the operations listed next. Each operation is identified by its corresponding name. The key for each operation is a string with its name prefixed by two underscores, __; for instance, the key for operation "add" is the string "__add". The semantics of these operations is better explained by a Lua function describing how the interpreter executes that operation.

The code shown here in Lua is only illustrative; the real behavior is hard coded in the interpreter and it is much more efficient than this simulation. All functions used in these descriptions (`rawget`, `tonumber`, etc.) are described in lua-lib-core. In particular, to retrieve the metamethod of a given object, we use the expression

```
metatable(obj)[event]
```

This should be read as

```
rawget(metatable(obj) or {}, event)
```

That is, the access to a metamethod does not invoke other metamethods, and the access to objects with no metatables does not fail (it simply results in `nil`).

"add": __add()
------ the + operation.

The function `getbinhandler` below defines how Lua chooses a handler for a binary operation. First, Lua tries the first operand. If its type does not define a handler for the operation, then Lua tries the second operand.

```
function getbinhandler (op1, op2, event)
  return metatable(op1)[event] or metatable(op2)[event]
end
```

By using this function, the behavior of the `op1 + op2` is

```
function add_event (op1, op2)
  local o1, o2 = tonumber(op1), tonumber(op2)
  if o1 and o2 then  -- both operands are numeric?
    return o1 + o2   -- `+` here is the primitive `add`
  else  -- at least one of the operands is not numeric
    local h = getbinhandler(op1, op2, "__add")
    if h then
      -- call the handler with both operands
      return h(op1, op2)
    else  -- no handler available: default behavior
      error(...)
    end
  end
end
```

"sub": __sub()
------ the - operation. Behavior similar to the "add" operation.

"mul": __mul()
------ the * operation. Behavior similar to the "add" operation.

"div": __div()
------ the / operation. Behavior similar to the "add" operation.

"mod": __mod()
------ the % operation. Behavior similar to the "add" operation, with the operation `o1 - floor(o1/o2)*o2` as the primitive operation.

"pow": __pow()
------ the ^ (exponentiation) operation. Behavior similar to the "add" operation, with the function pow (from the C math library) as the primitive operation.

"unm": __unm()
------ the unary - operation.

```
function unm_event (op)
  local o = tonumber(op)
  if o then  -- operand is numeric?
    return -o  -- `-` here is the primitive `unm`
  else  -- the operand is not numeric.
    -- Try to get a handler from the operand
    local h = metatable(op).__unm
    if h then
      -- call the handler with the operand
      return h(op)
    else  -- no handler available: default behavior
      error(...)
    end
  end
end
```

"concat": __concat()
--------- the `..` (concatenation) operation.

```
function concat_event (op1, op2)
  if (type(op1) == "string" or type(op1) == "number") and
     (type(op2) == "string" or type(op2) == "number") then
    return op1 .. op2  -- primitive string concatenation
  else
    local h = getbinhandler(op1, op2, "__concat")
    if h then
      return h(op1, op2)
    else
      error(...)
    end
  end
end
```

"len": __len()
------ the # operation.

```
function len_event (op)
  if type(op) == "string" then
    return strlen(op)         -- primitive string length
  elseif type(op) == "table" then
    return #op                -- primitive table length
  else
    local h = metatable(op).__len
    if h then
      -- call the handler with the operand
      return h(op)
    else  -- no handler available: default behavior
      error(...)
    end
  end
end
```

"eq": __eq()
----- the == operation.

The function `getcomphandler` defines how Lua chooses a metamethod for comparison operators. A metamethod only is selected when both objects being compared have the same type and the same metamethod for the selected operation.

```
function getcomphandler (op1, op2, event)
  if type(op1) ~= type(op2) then return nil end
  local mm1 = metatable(op1)[event]
  local mm2 = metatable(op2)[event]
  if mm1 == mm2 then return mm1 else return nil end
end
```

The "eq" event is defined as follows:

```
function eq_event (op1, op2)
  if type(op1) ~= type(op2) then  -- different types?
    return false   -- different objects
  end
  if op1 == op2 then   -- primitive equal?
    return true   -- objects are equal
  end
  -- try metamethod
  local h = getcomphandler(op1, op2, "__eq")
  if h then
    return h(op1, op2)
  else
    return false
  end
end
```

`a ~= b` is equivalent to `not (a == b)`.

"lt": __lt()
----- the < operation.

```
function lt_event (op1, op2)
  if type(op1) == "number" and type(op2) == "number" then
    return op1 < op2   -- numeric comparison
  elseif type(op1) == "string" and type(op2) == "string" then
    return op1 < op2   -- lexicographic comparison
  else
    local h = getcomphandler(op1, op2, "__lt")
    if h then
      return h(op1, op2)
    else
      error(...);
    end
  end
end
```

`a > b` is equivalent to `b < a`.

"le": __le()
----- the <= operation.

```
function le_event (op1, op2)
  if type(op1) == "number" and type(op2) == "number" then
    return op1 <= op2   -- numeric comparison
  elseif type(op1) == "string" and type(op2) == "string" then
    return op1 <= op2   -- lexicographic comparison
  else
    local h = getcomphandler(op1, op2, "__le")
    if h then
      return h(op1, op2)
    else
      h = getcomphandler(op1, op2, "__lt")
      if h then
        return not h(op2, op1)
      else
        error(...);
      end
    end
  end
end
```

`a >= b` is equivalent to `b <= a`. Note that, in the absence of a "le" metamethod, Lua tries the "lt", assuming that `a <= b` is equivalent to `not (b < a)`.

"index": __index()
-------- The indexing access `table[key]`.

```
function gettable_event (table, key)
  local h
  if type(table) == "table" then
    local v = rawget(table, key)
    if v ~= nil then return v end
    h = metatable(table).__index
    if h == nil then return nil end
  else
    h = metatable(table).__index
    if h == nil then
      error(...);
    end
  end
  if type(h) == "function" then
    return h(table, key)      -- call the handler
  else return h[key]          -- or repeat operation on it
end
```

"newindex": __newindex()
---------- The indexing assignment `table[key] = value`.

```
function settable_event (table, key, value)
  local h
  if type(table) == "table" then
    local v = rawget(table, key)
    if v ~= nil then rawset(table, key, value); return end
    h = metatable(table).__newindex
    if h == nil then rawset(table, key, value); return end
  else
    h = metatable(table).__newindex
    if h == nil then
      error(...);
    end
  end
  if type(h) == "function" then
    return h(table, key,value)    -- call the handler
  else h[key] = value             -- or repeat operation on it
end
```

"call": __call()
------- called when Lua calls a value.

```
function function_event (func, ...)
  if type(func) == "function" then
    return func(...)   -- primitive call
  else
    local h = metatable(func).__call
    if h then
      return h(func, ...)
    else
      error(...)
    end
  end
end
```

2.9 Environments

lua-environments

Besides metatables, objects of types thread, function, and userdata have another table associated with them, called their environment. Like metatables, environments are regular tables and multiple objects can share the same environment.

Environments associated with userdata have no meaning for Lua. It is only a convenience feature for programmers to associate a table to a userdata.

Environments associated with threads are called global environments. They are used as the default environment for their threads and non-nested functions created by the thread (through loadfile(), loadstring() or load()) and can be directly accessed by C code (see lua-pseudoindex).

Environments associated with C functions can be directly accessed by C code (see lua-pseudoindex). They are used as the default environment for other C functions created by the function.

Environments associated with Lua functions are used to resolve all accesses to global variables within the function (see lua-variables). They are used as the default environment for other Lua functions created by the function.

You can change the environment of a Lua function or the running thread by calling `setfenv`. You can get the environment of a Lua function or the running thread by calling `getfenv` (see lua_getfenv()). To manipulate the environment of other objects (userdata, C functions, other threads) you must use the C API.

2.10 Garbage Collection

lua-gc

Lua performs automatic memory management. This means that you do not have to worry neither about allocating memory for new objects nor about freeing it when the objects are no longer needed. Lua manages memory automatically by running a garbage collector from time to time to collect all dead objects (that is, these objects that are no longer accessible from Lua). All objects in Lua are subject to automatic management: tables, userdata, functions, threads, and strings.

Lua implements an incremental mark-and-sweep collector. It uses two numbers to control its garbage-collection cycles: the garbage-collector pause and the garbage-collector step multiplier.

The garbage-collector pause controls how long the collector waits before starting a new cycle. Larger values make the collector less aggressive. Values smaller than 1 mean the collector will not wait to start a new cycle. A value of 2 means that the collector waits for the total memory in use to double before starting a new cycle.

The step multiplier controls the relative speed of the collector relative to memory allocation. Larger values make the collector more aggressive but also increase the size of each incremental step. Values smaller than 1 make the collector too slow and may result in the collector never finishing a cycle. The default, 2, means that the collector runs at "twice" the speed of memory allocation.

You can change these numbers by calling `lua_gc` (see lua_gc()) in C or `collectgarbage` (see collectgarbage()) in Lua. Both get percentage points as arguments (so an argument of 100 means a real value of 1). With these functions you can also control the collector directly (e.g., stop and restart it).

2.10.1 Garbage-Collection Metamethods

lua-gc-meta

Using the C API, you can set garbage-collector metamethods for userdata (see lua-metatable). These metamethods are also called finalizers. Finalizers allow you to coordinate Lua's garbage collection with external resource management (such as closing files, network or database connections, or freeing your own memory).

__gc

Garbage userdata with a field `__gc` in their metatables are not collected immediately by the garbage collector. Instead, Lua puts them in a list. After the collection, Lua does the equivalent of the following function for each userdata in that list:

```
function gc_event (udata)
  local h = metatable(udata).__gc
  if h then
    h(udata)
  end
end
```

At the end of each garbage-collection cycle, the finalizers for userdata are called in reverse order of their creation, among these collected in that cycle. That is, the first finalizer to be called is the one associated with the userdata created last in the program.

2.10.2 - Weak Tables

lua-weaktable

A weak table is a table whose elements are weak references. A weak reference is ignored by the garbage collector. In other words, if the only references to an object are weak references, then the garbage collector will collect this object.

__mode

A weak table can have weak keys, weak values, or both. A table with weak keys allows the collection of its keys, but prevents the collection of its values. A table with both weak keys and weak values allows the collection of both keys and values. In any case, if either the key or the value is collected, the whole pair is removed from the table. The weakness of a table is controlled by the value of the `__mode` field of its metatable. If the `__mode` field is a string containing the character `k`, the keys in the table are weak. If `__mode` contains `v`, the values in the table are weak.

After you use a table as a metatable, you should not change the value of its field `__mode`. Otherwise, the weak behavior of the tables controlled by this metatable is undefined.

2.11 Coroutines

lua-coroutine

Lua supports coroutines, also called collaborative multithreading. A coroutine in Lua represents an independent thread of execution. Unlike threads in multithread systems, however, a coroutine only suspends its execution by explicitly calling a yield function.

You create a coroutine with a call to `coroutine.create` (see coroutine.create()). Its sole argument is a function that is the main function of the coroutine. The `create` function only creates a new coroutine and returns a handle to it (an object of type `thread`); it does not start the coroutine execution.

When you first call `coroutine.resume` (see coroutine.resume()), passing as its first argument the thread returned by `coroutine.create`, the coroutine starts its execution, at the first line of its main function. Extra arguments passed to `coroutine.resume` are passed on to the

coroutine main function. After the coroutine starts running, it runs until it terminates or `yields`.

A coroutine can terminate its execution in two ways: normally, when its main function returns (explicitly or implicitly, after the last instruction); and abnormally, if there is an unprotected error. In the first case, `coroutine.resume` returns `true`, plus any values returned by the coroutine main function. In case of errors, `coroutine.resume` returns `false` plus an error message.

A coroutine yields by calling `coroutine.yield` (see coroutine.yield()). When a coroutine yields, the corresponding `coroutine.resume` returns immediately, even if the yield happens inside nested function calls (that is, not in the main function, but in a function directly or indirectly called by the main function). In the case of a yield, `coroutine.resume` also returns `true`, plus any values passed to `coroutine.yield`. The next time you resume the same coroutine, it continues its execution from the point where it yielded, with the call to `coroutine.yield` returning any extra arguments passed to `coroutine.resume`.

Like `coroutine.create`, the `coroutine.wrap` function (see coroutine.wrap()) also creates a coroutine, but instead of returning the coroutine itself, it returns a function that, when called, resumes the coroutine. Any arguments passed to this function go as extra arguments to `coroutine.resume`. `coroutine.wrap` returns all the values returned by `coroutine.resume`, except the first one (the boolean error code). Unlike `coroutine.resume`, `coroutine.wrap` does not catch errors; any error is propagated to the caller.

As an example, consider the next code:

```
function foo1 (a)
  print("foo", a)
  return coroutine.yield(2*a)
end

co = coroutine.create(function (a,b)
      print("co-body", a, b)
      local r = foo1(a+1)
      print("co-body", r)
      local r, s = coroutine.yield(a+b, a-b)
      print("co-body", r, s)
      return b, "end"
end)

print("main", coroutine.resume(co, 1, 10))
print("main", coroutine.resume(co, "r"))
print("main", coroutine.resume(co, "x", "y"))
print("main", coroutine.resume(co, "x", "y"))
```

When you run it, it produces the following output:

```
co-body 1       10
foo     2
main    true    4
co-body r
main    true    11      -9
co-body x       y
main    true    10      end
main    false   cannot resume dead coroutine
```

3 THE APPLICATION PROGRAM INTERFACE

lua-API

This section describes the C API for Lua, that is, the set of C functions available to the host program to communicate with Lua. All API functions and related types and constants are declared in the header file `lua.h`.

Even when we use the term "function", any facility in the API may be provided as a `macro` instead. All such macros use each of its arguments exactly once (except for the first argument, which is always a Lua state), and so do not generate hidden side-effects.

As in most C libraries, the Lua API functions do not check their arguments for validity or consistency. However, you can change this behavior by compiling Lua with a proper definition for the macro `luai_apicheck`,in file `luaconf.h`.

3.1 The Stack

lua-stack lua-apiStack

Lua uses a virtual stack to pass values to and from C. Each element in this stack represents a Lua value (`nil`, number, string, etc.).

Whenever Lua calls C, the called function gets a new stack, which is independent of previous stacks and of stacks of C functions that are still active. This stack initially contains any arguments to the C function and it is where the C function pushes its results to be returned to the caller (see lua_CFunction).

lua-stackindex

For convenience, most query operations in the API do not follow a strict stack discipline. Instead, they can refer to any element in the stack by using an index: a positive index represents an absolute stack position (starting at 1); a negative index represents an offset from the top of the stack. More specifically, if the stack has n elements, then index 1 represents the first element (that is, the element that was pushed onto the stack first) and index n represents the last element; index `-1` also represents the last element (that is, the element at the top) and index `-n` represents the first element. We say that an index is valid if it lies between 1 and the stack top (that is, if `1 <= abs(index) <= top`).

3.2 Stack Size

lua-apiStackSize

When you interact with Lua API, you are responsible for ensuring consistency. In particular, you are responsible for controlling stack overflow. You can use the function `lua_checkstack` to grow the stack size (see lua_checkstack()).

Whenever Lua calls C, it ensures that at least `LUA_MINSTACK` stack positions are available. `LUA_MINSTACK` is defined as 20, so that usually you do not have to worry about stack space unless your code has loops pushing elements onto the stack.

Most query functions accept as indices any value inside the available stack space, that is, indices up to the maximum stack size you have set through `lua_checkstack`. Such indices are called acceptable indices. More formally, we define an acceptable index as follows:

```
(index < 0 && abs(index) <= top) || (index > 0 && index <= stackspace)
```

Note that 0 is never an acceptable index.

3.3 Pseudo-Indices lua-pseudoindex

Unless otherwise noted, any function that accepts valid indices can also be called with pseudo-indices, which represent some Lua values that are accessible to the C code but which are not in the stack. Pseudo-indices are used to access the thread environment, the function environment, the registry, and the upvalues of a C function (see lua-cclosure).

The thread environment (where global variables live) is always at pseudo-index `LUA_GLOBALSINDEX`. The environment of the running C function is always at pseudo-index `LUA_ENVIRONINDEX`.

To access and change the value of global variables, you can use regular table operations over an environment table. For instance, to access the value of a global variable, do

```
lua_getfield(L, LUA_GLOBALSINDEX, varname);
```

3.4 C Closures lua-cclosure

When a C function is created, it is possible to associate some values with it, thus creating a C closure; these values are called upvalues and are accessible to the function whenever it is called (see lua_pushcclosure()).

Whenever a C function is called, its upvalues are located at specific pseudo-indices. These pseudo-indices are produced by the macro `lua_upvalueindex`. The first value associated with a function is at position `lua_upvalueindex(1)`, and so on. Any access to `lua_upvalueindex( n )`, where n is greater than the number of upvalues of the current function, produces an acceptable (but invalid) index.

3.5 Registry lua-registry

Lua provides a registry, a pre-defined table that can be used by any C code to store whatever Lua value it needs to store. This table is always located at pseudo-index `LUA_REGISTRYINDEX`. Any C library can store data into this table, but it should take care to choose keys different from those used by other libraries, to avoid collisions. Typically, you should use as key a string containing your library name or a light userdata with the address of a C object in your code.

The integer keys in the registry are used by the reference mechanism, implemented by the auxiliary library, and therefore should not be used for other purposes.

3.6 Error Handling in C lua-apiError

Internally, Lua uses the C `longjmp` facility to handle errors. (You can also choose to use exceptions if you use C++; see file `luaconf.h`.) When Lua faces any error (such as memory allocation errors, type errors, syntax errors, and runtime errors) it raises an error; that is, it does a long jump. A protected environment uses `setjmp` to set a recover point; any error jumps to the most recent active recover point.

Almost any function in the API may raise an error, for instance due to a memory allocation error. The following functions run in protected mode (that is, they create a protected environment to run), so they never raise an error: `lua_newstate`, `lua_close`, `lua_load`, `lua_pcall`, and `lua_cpcall` (see lua_newstate(), lua_close(), lua_load(), lua_pcall(), and lua_cpcall()).

Inside a C function you can raise an error by calling `lua_error` (see lua_error()).

3.7 Functions and Types lua-apiFunctions

Here we list all functions and types from the C API in alphabetical order.

lua_Alloc lua_Alloc

```
typedef void * (*lua_Alloc) (void *ud,
                             void *ptr,
                             size_t osize,
                             size_t nsize);
```

The type of the memory-allocation function used by Lua states. The allocator function must provide a functionality similar to `realloc`, but not exactly the same. Its arguments are ud, an opaque pointer passed to `lua_newstate` (see lua_newstate()); `ptr`, a pointer to the block being allocated/reallocated/freed; `osize`, the original size of the block; `nsize`, the new size of the block. `ptr` is `NULL` if and only if `osize` is zero. When `nsize` is zero, the allocator must return `NULL`; if `osize` is not zero, it should free the block pointed to by `ptr`. When `nsize` is not zero, the allocator returns `NULL` if and only if it cannot fill the request. When `nsize` is not zero and `osize` is zero, the allocator should behave like `malloc`. When `nsize` and `osize` are not zero, the allocator behaves like `realloc`. Lua assumes that the allocator never fails when `osize >= nsize`.

Here is a simple implementation for the allocator function. It is used in the auxiliary library by `luaL_newstate` (see luaL_newstate()).

```
static void *l_alloc (void *ud, void *ptr, size_t osize,
                                           size_t nsize) {
  (void)ud;  (void)osize;  /* not used */
  if (nsize == 0) {
    free(ptr);
    return NULL;
  }
  else
    return realloc(ptr, nsize);
}
```

This code assumes that `free(NULL)` has no effect and that `realloc(NULL, size)` is equivalent to `malloc(size)`. ANSI C ensures both behaviors.

lua_atpanic lua_atpanic()

```
lua_CFunction lua_atpanic (lua_State *L, lua_CFunction panicf);
```

Sets a new panic function and returns the old one.

If an error happens outside any protected environment, Lua calls a `panic function` and then calls `exit(EXIT_FAILURE)`, thus exiting the host application. Your panic function may avoid this exit by never returning (e.g., doing a long jump).

The panic function can access the error message at the top of the stack.

lua_call lua_call()

```
void lua_call (lua_State *L, int nargs, int nresults);
```

Calls a function.

To call a function you must use the following protocol: first, the function to be called is pushed onto the stack; then, the arguments to the function are pushed in direct order; that is, the first argument is pushed first. Finally you call `lua_call`; `nargs` is the number of arguments that you pushed onto the stack. All arguments and the function value are popped from the stack when the function is called. The function results are pushed onto the stack when the function returns. The number of results is adjusted to `nresults`, unless `nresults` is `LUA_MULTRET`. In this case, `all` results from the function are pushed. Lua takes care that the returned values fit into the stack space. The function results are pushed onto the stack in direct order (the first result is pushed first), so that after the call the last result is on the top of the stack.

Any error inside the called function is propagated upwards (with a `longjmp`).

The following example shows how the host program may do the equivalent to this Lua code:

```
a = f("how", t.x, 14)
```

Here it is in C:

```
lua_getfield(L, LUA_GLOBALSINDEX, "f"); // function to be called
lua_pushstring(L, "how");                       // 1st argument
lua_getfield(L, LUA_GLOBALSINDEX, "t");   // table to be indexed
lua_getfield(L, -1, "x");        // push result of t.x (2nd arg)
lua_remove(L, -2);                  // remove 't' from the stack
lua_pushinteger(L, 14);                         // 3rd argument
lua_call(L, 3, 1);     // call 'f' with 3 arguments and 1 result
lua_setfield(L, LUA_GLOBALSINDEX, "a");        // set global 'a'
```

Note that the code above is "balanced": at its end, the stack is back to its original configuration. This is considered good programming practice.

lua_CFunction lua-cfunction lua_CFunction

```
typedef int (*lua_CFunction) (lua_State *L);
```

Type for C functions.

In order to communicate properly with Lua, a C function must use the following protocol, which defines the way parameters and results are passed: a C function receives its arguments from Lua in its stack in direct order (the first argument is pushed first). So, when the function starts, `lua_gettop(L)` (see lua_gettop()) returns the number of arguments received by the function. The first argument (if any) is at index 1 and its last argument is at index `lua_gettop(L)`. To return values to Lua, a C function just pushes them onto the stack, in direct order (the first result is pushed first), and returns the number of results. Any other value in the stack below the results will be properly discarded by Lua. Like a Lua function, a C function called by Lua can also return many results.

lua-cfunctionexample

As an example, the following function receives a variable number of numerical arguments and returns their average and sum:

```
static int foo (lua_State *L) {
  int n = lua_gettop(L);    /* number of arguments */
  lua_Number sum = 0;
  int i;
  for (i = 1; i &lt;= n; i++) {
    if (!lua_isnumber(L, i)) {
      lua_pushstring(L, "incorrect argument");
      lua_error(L);
    }
    sum += lua_tonumber(L, i);
  }
  lua_pushnumber(L, sum/n); /* first result */
  lua_pushnumber(L, sum);   /* second result */
  return 2;                 /* number of results */
}
```

lua_checkstack lua_checkstack()

```
int lua_checkstack (lua_State *L, int extra);
```

Ensures that there are at least `extra` free stack slots in the stack. It returns false if it cannot grow the stack to that size. This function never shrinks the stack; if the stack is already larger than the new size, it is left unchanged.

lua_close lua_close()

```
void lua_close (lua_State *L);
```

Destroys all objects in the given Lua state (calling the corresponding garbage-collection metamethods, if any) and frees all dynamic memory used by this state. On several platforms, you may not need to call this function, because all resources are naturally released when the host

program ends. On the other hand, long-running programs, such as a daemon or a web server, might need to release states as soon as they are not needed, to avoid growing too large.

lua_concat lua_concat()

```
void lua_concat (lua_State *L, int n);
```

Concatenates the n values at the top of the stack, pops them, and leaves the result at the top. If n is 1, the result is the single string on the stack (that is, the function does nothing); if n is 0, the result is the empty string. Concatenation is done following the usual semantics of Lua (see lua-concat).

lua_cpcall lua_cpcall()

```
int lua_cpcall (lua_State *L, lua_CFunction func, void *ud);
```

Calls the C function `func` in protected mode. `func` starts with only one element in its stack, a light userdata containing `ud`. In case of errors, `lua_cpcall` returns the same error codes as `lua_pcall` (see lua_pcall()), plus the error object on the top of the stack; otherwise, it returns zero, and does not change the stack. All values returned by `func` are discarded.

lua_createtable lua_createtable()

```
void lua_createtable (lua_State *L, int narr, int nrec);
```

Creates a new empty table and pushes it onto the stack. The new table has space pre-allocated for `narr` array elements and `nrec` non-array elements. This pre-allocation is useful when you know exactly how many elements the table will have. Otherwise you can use the function `lua_newtable` (see lua_newtable()).

lua_dump lua_dump()

```
int lua_dump (lua_State *L, lua_Writer writer, void *data);
```

Dumps a function as a binary chunk. Receives a Lua function on the top of the stack and produces a binary chunk that, if loaded again, results in a function equivalent to the one dumped. As it produces parts of the chunk, `lua_dump` calls function `writer` (see lua_Writer) with the given `data` to write them.

The value returned is the error code returned by the last call to the writer; 0 means no errors.

This function does not pop the Lua function from the stack.

lua_equal lua_equal()

```
int lua_equal (lua_State *L, int index1, int index2);
```

Returns 1 if the two values in acceptable indices `index1` and `index2` are equal, following the semantics of the Lua == operator (that is, may call metamethods). Otherwise returns 0. Also returns 0 if any of the indices is non valid.

lua_error lua_error()

```
int lua_error (lua_State *L);
```

Generates a Lua error. The error message (which can actually be a Lua value of any type) must be on the stack top. This function does a long jump, and therefore never returns (see luaL_error()).

lua_gc lua_gc()

```
int lua_gc (lua_State *L, int what, int data);
```

Controls the garbage collector.

This function performs several tasks, according to the value of the parameter `what`:

- `LUA_GCSTOP` stops the garbage collector.
- `LUA_GCRESTART` restarts the garbage collector.
- `LUA_GCCOLLECT` performs a full garbage-collection cycle.
- `LUA_GCCOUNT` returns the current amount of memory (in Kbytes) in use by Lua.
- `LUA_GCCOUNTB` returns the remainder of dividing the current amount of bytes of memory in use by Lua by 1024.
- `LUA_GCSTEP` performs an incremental step of garbage collection. The step "size" is controlled by `data` (larger values mean more steps) in a non-specified way. If you want to control the step size you must experimentally tune the value of `data`. The function returns 1 if the step finished a garbage-collection cycle.
- `LUA_GCSETPAUSE` sets `data` /100 as the new value for the `pause` of the collector (see lua-gc). The function returns the previous value of the pause.
- `LUA_GCSETSTEPMUL`sets `data` /100 as the new value for the `step multiplier` of the collector (see lua-gc). The function returns the previous value of the step multiplier.

lua_getallocf lua_getallocf()

```
lua_Alloc lua_getallocf (lua_State *L, void **ud);
```

Returns the memory-allocation function of a given state. If ud is not `NULL`, Lua stores in *ud the opaque pointer passed to `lua_newstate` (see lua_newstate()).

lua_getfenv lua_getfenv()

```
void lua_getfenv (lua_State *L, int index);
```

Pushes onto the stack the environment table of the value at the given index.

lua_getfield lua_getfield()

```
void lua_getfield (lua_State *L, int index, const char *k);
```

Pushes onto the stack the value `t[k]`, where `t` is the value at the given valid index `index`. As in Lua, this function may trigger a metamethod for the "index" event (see lua-metatable).

lua_getglobal lua_getglobal()

```
void lua_getglobal (lua_State *L, const char *name);
```

Pushes onto the stack the value of the global `name`. It is defined as a macro:

```
#define lua_getglobal(L,s)  lua_getfield(L, LUA_GLOBALSINDEX, s)
```

lua_getmetatable lua_getmetatable()

```
int lua_getmetatable (lua_State *L, int index);
```

Pushes onto the stack the metatable of the value at the given acceptable index. If the index is not valid, or if the value does not have a metatable, the function returns 0 and pushes nothing on the stack.

lua_gettable lua_gettable()

```
void lua_gettable (lua_State *L, int index);
```

Pushes onto the stack the value `t[k]`, where `t` is the value at the given valid index `index` and `k` is the value at the top of the stack.

This function pops the key from the stack (putting the resulting value in its place). As in Lua, this function may trigger a metamethod for the "index" event (see lua-metatable).

lua_gettop lua_gettop()

```
int lua_gettop (lua_State *L);
```

Returns the index of the top element in the stack. Because indices start at 1, this result is equal to the number of elements in the stack (and so 0 means an empty stack).

lua_insert lua_insert()

```
void lua_insert (lua_State *L, int index);
```

Moves the top element into the given valid index, shifting up the elements above this index to open space. Cannot be called with a pseudo-index, because a pseudo-index is not an actual stack position.

lua_Integer lua_Integer

```
typedef ptrdiff_t lua_Integer;
```

The type used by the Lua API to represent integral values.

By default it is a `ptrdiff_t`, which is usually the largest integral type the machine handles "comfortably".

lua_isboolean lua_isboolean()

```
int lua_isboolean (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index has type boolean, and 0 otherwise.

lua_iscfunction lua_iscfunction()

```
int lua_iscfunction (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a C function, and 0 otherwise.

lua_isfunction lua_isfunction()

```
int lua_isfunction (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a function (either C or Lua), and 0 otherwise.

lua_islightuserdata lua_islightuserdata()

```
int lua_islightuserdata (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a light userdata, and 0 otherwise.

lua_isnil lua_isnil()

```
int lua_isnil (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is `nil`, and 0 otherwise.

lua_isnumber lua_isnumber()

```
int lua_isnumber (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a number or a string convertible to a number, and 0 otherwise.

lua_isstring lua_isstring()

```
int lua_isstring (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a string or a number (which is always convertible to a string), and 0 otherwise.

lua_istable lua_istable()

```
int lua_istable (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a table, and 0 otherwise.

lua_isthread lua_isthread()

```
int lua_isthread (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a thread, and 0 otherwise.

lua_isuserdata lua_isuserdata()

```
int lua_isuserdata (lua_State *L, int index);
```

Returns 1 if the value at the given acceptable index is a userdata (either full or light), and 0 otherwise.

lua_lessthan lua_lessthan()

```
int lua_lessthan (lua_State *L, int index1, int index2);
```

Returns 1 if the value at acceptable index `index1` is smaller than the value at acceptable index `index2`, following the semantics of the Lua < operator (that is, may call metamethods). Otherwise returns 0. Also returns 0 if any of the indices is non valid.

lua_load lua_load()

```
int lua_load (lua_State *L,
              lua_Reader reader,
              void *data,
              const char *chunkname);
```

Loads a Lua chunk. If there are no errors, `lua_load` pushes the compiled chunk as a Lua function on top of the stack. Otherwise, it pushes an error message. The return values of `lua_load` are:

- `0`: no errors;
- `LUA_ERRSYNTAX` : syntax error during pre-compilation;
- `LUA_ERRMEM` : memory allocation error.

This function only loads a chunk; it does not run it.

`lua_load` automatically detects whether the chunk is text or binary, and loads it accordingly (see program `luac`).

The `lua_load` function uses a user-supplied `reader` function to read the chunk (see lua_Reader). The `data` argument is an opaque value passed to the reader function.

The `chunkname` argument gives a name to the chunk, which is used for error messages and in debug information (see lua-apiDebug).

lua_newstate lua_newstate()

```
lua_State *lua_newstate (lua_Alloc f, void *ud);
```

Creates a new, independent state. Returns `NULL` if cannot create the state (due to lack of memory). The argument `f` is the allocator function; Lua does all memory allocation for this state through this function. The second argument, `ud`, is an opaque pointer that Lua simply passes to the allocator in every call.

lua_newtable lua_newtable()

```
void lua_newtable (lua_State *L);
```

Creates a new empty table and pushes it onto the stack. It is equivalent to `lua_createtable(L, 0, 0)` (see lua_createtable()).

lua_newthread lua_newthread()

```
lua_State *lua_newthread (lua_State *L);
```

Creates a new thread, pushes it on the stack, and returns a pointer to a `lua_State` (see lua_State) that represents this new thread. The new state returned by this function shares with the original state all global objects (such as tables), but has an independent execution stack.

There is no explicit function to close or to destroy a thread. Threads are subject to garbage collection, like any Lua object.

lua_newuserdata lua_newuserdata()

```
void *lua_newuserdata (lua_State *L, size_t size);
```

This function allocates a new block of memory with the given size, pushes onto the stack a new full userdata with the block address, and returns this address. userdata

Userdata represents C values in Lua. A full userdata represents a block of memory. It is an object (like a table): you must create it, it can have its own metatable, and you can detect when it is being collected. A full userdata is only equal to itself (under raw equality).

When Lua collects a full userdata with a `gc` metamethod, Lua calls the metamethod and marks the userdata as finalized. When this userdata is collected again then Lua frees its corresponding memory.

lua_next lua_next()

```
int lua_next (lua_State *L, int index);
```

Pops a key from the stack, and pushes a key-value pair from the table at the given index (the "next" pair after the given key). If there are no more elements in the table, then `lua_next` returns 0 (and pushes nothing).

lua-tabletraversal

A typical traversal looks like this:

```
/* table is in the stack at index 't' */
lua_pushnil(L);  /* first key */
while (lua_next(L, t) != 0) {
  /* uses 'key' (at index -2) and 'value' (at index -1) */
  printf("%s - %s\n",
         lua_typename(L, lua_type(L, -2)),
         lua_typename(L, lua_type(L, -1)));
  /* removes 'value'; keeps 'key' for next iteration */
  lua_pop(L, 1);
}
```

While traversing a table, do not call `lua_tolstring` (see lua_tolstring()) directly on a key, unless you know that the key is actually a string. Recall that `lua_tolstring` changes the value at the given index; this confuses the next call to `lua_next`.

lua_Number lua_Number

```
typedef double lua_Number;
```

The type of numbers in Lua. By default, it is double, but that can be changed in `luaconf.h`.

Through the configuration file you can change Lua to operate with another type for numbers (e.g., float or long).

lua_objlen lua_objlen()

```
size_t lua_objlen (lua_State *L, int index);
```

Returns the "length" of the value at the given acceptable index: for strings, this is the string length; for tables, this is the result of the length operator (#); for userdata, this is the size of the block of memory allocated for the userdata; for other values, it is 0.

lua_pcall lua_pcall()

```
lua_pcall (lua_State *L, int nargs, int nresults, int errfunc);
```

Calls a function in protected mode.

Both `nargs` and `nresults` have the same meaning as in `lua_call` (see lua_call()). If there are no errors during the call, `lua_pcall` behaves exactly like `lua_call`. However, if there is any error, `lua_pcall` catches it, pushes a single value on the stack (the error message), and returns an error code. Like `lua_call`, `lua_pcall` always removes the function and its arguments from the stack.

If `errfunc` is 0, then the error message returned on the stack is exactly the original error message. Otherwise, `errfunc` is the stack index of an `error handler function`. (In the current implementation, this index cannot be a pseudo-index.) In case of runtime errors, this function will be called with the error message and its return value will be the message returned on the stack by `lua_pcall`.

Typically, the error handler function is used to add more debug information to the error message, such as a stack traceback. Such information cannot be gathered after the return of `lua_pcall`, since by then the stack has unwound.

The `lua_pcall` function returns 0 in case of success or one of the following error codes (defined in `lua.h`):

- `LUA_ERRRUN` a runtime error.
- `LUA_ERRMEM` memory allocation error. For such errors, Lua does not call the error handler function.
- `LUA_ERRERR` error while running the error handler function.

lua_pop lua_pop()

```
void lua_pop (lua_State *L, int n);
```

Pops n elements from the stack.

lua_pushboolean lua_pushboolean()

```
void lua_pushboolean (lua_State *L, int b);
```

Pushes a boolean value with value b onto the stack.

lua_pushcclosure lua_pushcclosure()

```
void lua_pushcclosure (lua_State *L, lua_CFunction fn, int n);
```

Pushes a new C closure onto the stack.

When a C function is created, it is possible to associate some values with it, thus creating a C closure (see lua-cclosure); these values are then accessible to the function whenever it is called. To associate values with a C function, first these values should be pushed onto the stack (when there are multiple values, the first value is pushed first). Then `lua_pushcclosure` is called to create and push the C function onto the stack, with the argument n telling how many values should be associated with the function. `lua_pushcclosure` also pops these values from the stack.

lua_pushcfunction lua_pushcfunction()

```
void lua_pushcfunction (lua_State *L, lua_CFunction f);
```

Pushes a C function onto the stack. This function receives a pointer to a C function and pushes onto the stack a Lua value of type `function` that, when called, invokes the corresponding C function.

Any function to be registered in Lua must follow the correct protocol to receive its parameters and return its results (see lua_CFunction).

`lua_pushcfunction` is defined as a macro:

```
#define lua_pushcfunction(L,f)  lua_pushcclosure(L,f,0)
```

lua_pushfstring lua_pushfstring()

```
const char *lua_pushfstring (lua_State *L, const char *fmt, ...);
```

Pushes onto the stack a formatted string and returns a pointer to this string. It is similar to the C function `sprintf`, but has some important differences:

- You do not have to allocate space for the result: the result is a Lua string and Lua takes care of memory allocation (and deallocation, through garbage collection).
- The conversion specifiers are quite restricted. There are no flags, widths, or precisions. The conversion specifiers can only be `%%` (inserts a `%` in the string), `%s` (inserts a zero-terminated string, with no size restrictions), `%f` (inserts a `lua_Number`), `%p` (inserts a pointer as a hexadecimal numeral), `%d` (inserts an `int`), and `%c` (inserts an `int` as a character).

lua_pushinteger lua_pushinteger()

```
void lua_pushinteger (lua_State *L, lua_Integer n);
```

Pushes a number with value n onto the stack.

lua_pushlightuserdata lua_pushlightuserdata()

```
void lua_pushlightuserdata (lua_State *L, void *p);
```

Pushes a light userdata onto the stack. lua-lightuserdata
Userdata represents C values in Lua. A light userdata represents a pointer. It is a value (like a number): you do not create it, it has no individual metatable, and it is not collected (as it was never created). A light userdata is equal to "any" light userdata with the same C address.

lua_pushlstring lua_pushlstring()

```
void lua_pushlstring (lua_State *L, const char *s, size_t len);
```

Pushes the string pointed to by `s` with size `len` onto the stack. Lua makes (or reuses) an internal copy of the given string, so the memory at `s` can be freed or reused immediately after the function returns. The string can contain embedded zeros.

lua_pushnil lua_pushnil()

```
void lua_pushnil (lua_State *L);
```

Pushes a nil value onto the stack.

lua_pushnumber lua_pushnumber()

```
void lua_pushnumber (lua_State *L, lua_Number n);
```

Pushes a number with value n onto the stack.

lua_pushstring lua_pushstring()

```
void lua_pushstring (lua_State *L, const char *s);
```

Pushes the zero-terminated string pointed to by `s` onto the stack. Lua makes (or reuses) an internal copy of the given string, so the memory at `s` can be freed or reused immediately after the function returns. The string cannot contain embedded zeros; it is assumed to end at the first zero.

lua_pushthread lua_pushthread()

```
int lua_pushthread (lua_State *L);
```

Pushes the thread represented by L onto the stack. Returns 1 if this thread is the main thread of its state.

lua_pushvalue lua_pushvalue()

```
void lua_pushvalue (lua_State *L, int index);
```

Pushes a copy of the element at the given valid index onto the stack.

lua_pushvfstring lua_pushvfstring()

```
const char *lua_pushvfstring (lua_State *L,
                              const char *fmt,
                              va_list argp);
```

Equivalent to `lua_pushfstring` (see lua_pushfstring()), except that it receives a `va_list` instead of a variable number of arguments.

lua_rawequal lua_rawequal()

```
int lua_rawequal (lua_State *L, int index1, int index2);
```

Returns 1 if the two values in acceptable indices `index1` and `index2` are primitively equal (that is, without calling metamethods). Otherwise returns 0. Also returns 0 if any of the indices are non valid.

lua_rawget lua_rawget()

```
void lua_rawget (lua_State *L, int index);
```

Similar to `lua_gettable` (see lua_gettable()), but does a raw access (i.e., without metamethods).

lua_rawgeti lua_rawgeti()

```
void lua_rawgeti (lua_State *L, int index, int n);
```

Pushes onto the stack the value `t[n]`, where `t` is the value at the given valid index `index`. The access is raw; that is, it does not invoke metamethods.

lua_rawset lua_rawset()

```
void lua_rawset (lua_State *L, int index);
```

Similar to `lua_settable` (see lua_settable()), but does a raw assignment (i.e., without metamethods).

lua_rawseti lua_rawseti()

```
void lua_rawseti (lua_State *L, int index, int n);
```

Does the equivalent of `t[n] = v`, where `t` is the value at the given valid index `index` and `v` is the value at the top of the stack.

This function pops the value from the stack. The assignment is raw; that is, it does not invoke metamethods.

lua_Reader lua_Reader

```
typedef const char * (*lua_Reader) (lua_State *L,
                                    void *data,
                                    size_t *size);
```

The reader function used by `lua_load` (see lua_load()). Every time it needs another piece of the chunk, `lua_load` calls the reader, passing along its `data` parameter. The reader must return a pointer to a block of memory with a new piece of the chunk and set `size` to the block size. The block must exist until the reader function is called again. To signal the end of the chunk, the reader must return `NULL`. The reader function may return pieces of any size greater than zero.

lua_register lua_register()

```
void lua_register (lua_State *L,
                   const char *name,
                   lua_CFunction f);
```

Sets the C function `f` as the new value of global `name`. It is defined as a macro:

```
#define lua_register(L,n,f) \
       (lua_pushcfunction(L, f), lua_setglobal(L, n))
```

lua_remove lua_remove()

```
void lua_remove (lua_State *L, int index);
```

Removes the element at the given valid index, shifting down the elements above this index to fill the gap. Cannot be called with a pseudo-index, because a pseudo-index is not an actual stack position.

lua_replace lua_replace()

```
void lua_replace (lua_State *L, int index);
```

Moves the top element into the given position (and pops it), without shifting any element (therefore replacing the value at the given position).

lua_resume lua_resume()

```
int lua_resume (lua_State *L, int narg);
```

Starts and resumes a coroutine in a given thread.

To start a coroutine, you first create a new thread (see lua_newthread()); then you push onto its stack the main function plus any arguments; then you call `lua_resume` (see lua_resume()) with `narg` being the number of arguments. This call returns when the coroutine suspends or finishes its execution. When it returns, the stack contains all values passed to `lua_yield` (see lua_yield()), or all values returned by the body function. `lua_resume` returns `LUA_YIELD` if the coroutine yields, 0 if the coroutine finishes its execution without errors, or an error code in case of errors (see lua_pcall()). In case of errors, the stack is not unwound, so you can use the debug API over it. The error message is on the top of the stack. To restart a coroutine, you put on its stack only the values to be passed as results from `lua_yield`, and then call `lua_resume`.

lua_setallocf lua_setallocf()

```
void lua_setallocf (lua_State *L, lua_Alloc f, void *ud);
```

Changes the allocator function of a given state to `f` with user data `ud`.

lua_setfenv lua_setfenv()

```
int lua_setfenv (lua_State *L, int index);
```

Pops a table from the stack and sets it as the new environment for the value at the given index. If the value at the given index is neither a function nor a thread nor a userdata, `lua_setfenv` returns 0. Otherwise it returns 1.

lua_setfield lua_setfield()

```
void lua_setfield (lua_State *L, int index, const char *k);
```

Does the equivalent to `t[k] = v`, where `t` is the value at the given valid index `index` and `v` is the value at the top of the stack.

This function pops the value from the stack. As in Lua, this function may trigger a metamethod for the "newindex" event (see lua-metatable).

lua_setglobal lua_setglobal()

```
void lua_setglobal (lua_State *L, const char *name);
```

Pops a value from the stack and sets it as the new value of global `name`. It is defined as a macro:

```
#define lua_setglobal(L,s)   lua_setfield(L, LUA_GLOBALSINDEX, s)
```

lua_setmetatable lua_setmetatable()

```
int lua_setmetatable (lua_State *L, int index);
```

Pops a table from the stack and sets it as the new metatable for the value at the given acceptable index.

lua_settable lua_settable()

```
void lua_settable (lua_State *L, int index);
```

Does the equivalent to `t[k] = v`, where `t` is the value at the given valid index `index`, `v` is the value at the top of the stack, and `k` is the value just below the top.

This function pops both the key and the value from the stack. As in Lua, this function may trigger a metamethod for the "newindex" event (see lua-metatable).

lua_settop lua_settop()

```
void lua_settop (lua_State *L, int index);
```

Accepts any acceptable index, or 0, and sets the stack top to this index. If the new top is larger than the old one, then the new elements are filled with `nil`. If `index` is 0, then all stack elements are removed.

lua_State lua_State

```
typedef struct lua_State lua_State;
```

Opaque structure that keeps the whole state of a Lua interpreter. The Lua library is fully reentrant: it has no global variables. All information about a state is kept in this structure.

A pointer to this state must be passed as the first argument to every function in the library, except to `lua_newstate` (see lua_newstate()), which creates a Lua state from scratch.

lua_status lua_status()

```
int lua_status (lua_State *L);
```

Returns the status of the thread L.

The status can be 0 for a normal thread, an error code if the thread finished its execution with an error, or `LUA_YIELD` if the thread is suspended.

lua_toboolean lua_toboolean()

```
int lua_toboolean (lua_State *L, int index);
```

Converts the Lua value at the given acceptable index to a C boolean value (0 or 1). Like all tests in Lua, `lua_toboolean` returns 1 for any Lua value different from `false` and `nil`; otherwise it returns 0. It also returns 0 when called with a non-valid index. (If you want to accept only actual boolean values, use `lua_isboolean` lua_isboolean() to test the value's type.)

lua_tocfunction lua_tocfunction()

```
lua_CFunction lua_tocfunction (lua_State *L, int index);
```

Converts a value at the given acceptable index to a C function. That value must be a C function; otherwise it returns `NULL`.

lua_tointeger lua_tointeger()

```
lua_Integer lua_tointeger (lua_State *L, int idx);
```

Converts the Lua value at the given acceptable index to the signed integral type `lua_Integer` (see lua_Integer). The Lua value must be a number or a string convertible to a number (see lua-coercion); otherwise, `lua_tointeger` returns 0.

If the number is not an integer, it is truncated in some non-specified way.

lua_tolstring lua_tolstring()

```
const char *lua_tolstring (lua_State *L, int index, size_t *len);
```

Converts the Lua value at the given acceptable index to a C string. If `len` is not `NULL`, it also sets `*len` with the string length. The Lua value must be a string or a number; otherwise, the function returns `NULL`. If the value is a number, then `lua_tolstring` also changes `the actual value in the stack to a string`. (This change confuses `lua_next` lua_next() when `lua_tolstring` is applied to keys during a table traversal.)

`lua_tolstring` returns a fully aligned pointer to a string inside the Lua state. This string always has a zero (`\0`) after its last character (as in C), but may contain other zeros in its body. Because Lua has garbage collection, there is no guarantee that the pointer returned by `lua_tolstring` will be valid after the corresponding value is removed from the stack.

lua_tonumber lua_tonumber()

```
lua_Number lua_tonumber (lua_State *L, int index);
```

Converts the Lua value at the given acceptable index to the C type `lua_Number` (see lua_Number). The Lua value must be a number or a string convertible to a number (see lua-coercion); otherwise, `lua_tonumber` returns 0.

lua_topointer lua_topointer()

```
const void *lua_topointer (lua_State *L, int index);
```

Converts the value at the given acceptable index to a generic C pointer (`void*`). The value may be a userdata, a table, a thread, or a function; otherwise, `lua_topointer` returns `NULL`. Different objects will give different pointers. There is no way to convert the pointer back to its original value.

Typically this function is used only for debug information.

lua_tostring lua_tostring()

```
const char *lua_tostring (lua_State *L, int index);
```

Equivalent to `lua_tolstring` (see lua_tolstring()) with `len` equal to `NULL`.

lua_tothread lua_tothread()

```
lua_State *lua_tothread (lua_State *L, int index);
```

Converts the value at the given acceptable index to a Lua thread (represented as `lua_State*` lua_State). This value must be a thread; otherwise, the function returns `NULL`.

lua_touserdata lua_touserdata()

```
void *lua_touserdata (lua_State *L, int index);
```

If the value at the given acceptable index is a full userdata, returns its block address. If the value is a light userdata, returns its pointer. Otherwise, it returns `NULL`.

lua_type lua_type()

```
int lua_type (lua_State *L, int index);
```

Returns the type of the value in the given acceptable index, or `LUA_TNONE` for a non-valid index (that is, an index to an "empty" stack position). The types returned by `lua_type` are coded by the following constants defined in `lua.h` : `LUA_TNIL`, `LUA_TNUMBER`, `LUA_TBOOLEAN`, `LUA_TSTRING`, `LUA_TTABLE`, `LUA_TFUNCTION`, `LUA_TUSERDATA`, `LUA_TTHREAD`, and `LUA_TLIGHTUSERDATA`.

lua_typename lua_typename()

```
const char *lua_typename  (lua_State *L, int tp);
```

Returns the name of the type encoded by the value `tp`, which must be one the values returned by `lua_type`.

lua_Writer lua_Writer

```
typedef int (*lua_Writer) (lua_State *L,
                           const void* p,
                           size_t sz,
                           void* ud);
```

The writer function used by `lua_dump` (see lua_dump()). Every time it produces another piece of chunk, `lua_dump` calls the writer, passing along the buffer to be written (`p`), its size (`sz`), and the `data` parameter supplied to `lua_dump`.

The writer returns an error code: 0 means no errors; any other value means an error and stops `lua_dump` from calling the writer again.

lua_xmove lua_xmove()

```
void lua_xmove (lua_State *from, lua_State *to, int n);
```

Exchange values between different threads of the `same` global state.

This function pops `n` values from the stack `from`, and pushes them onto the stack `to`.

lua_yield lua_yield()

```
int lua_yield (lua_State *L, int nresults);
```

Yields a coroutine.

This function should only be called as the return expression of a C function, as follows:

```
return lua_yield (L, nresults);
```

When a C function calls `lua_yield` in that way, the running coroutine suspends its execution, and the call to `lua_resume` (see lua_resume()) that started this coroutine returns. The parameter `nresults` is the number of values from the stack that are passed as results to `lua_resume`.

lua-stackexample

As an example of stack manipulation, if the stack starts as `10 20 30 40 50*` (from bottom to top; the * marks the top), then

```
lua_pushvalue(L, 3)    --> 10 20 30 40 50 30*
lua_pushvalue(L, -1)   --> 10 20 30 40 50 30 30*
lua_remove(L, -3)      --> 10 20 30 40 30 30*
lua_remove(L,  6)      --> 10 20 30 40 30*
lua_insert(L,  1)      --> 30 10 20 30 40*
lua_insert(L, -1)      --> 30 10 20 30 40*  (no effect)
lua_replace(L, 2)      --> 30 40 20 30*
lua_settop(L, -3)      --> 30 40*
lua_settop(L,  6)      --> 30 40 nil nil nil nil*
```

3.8 The Debug Interface

lua-apiDebug

Lua has no built-in debugging facilities. Instead, it offers a special interface by means of functions and hooks. This interface allows the construction of different kinds of debuggers, profilers, and other tools that need "inside information" from the interpreter.

lua_Debug

lua_Debug

```
typedef struct lua_Debug {
    int event;
    const char *name;           /* (n) */
    const char *namewhat;       /* (n) */
    const char *what;           /* (S) */
    const char *source;         /* (S) */
    int currentline;            /* (l) */
    int nups;                   /* (u) number of upvalues */
    int linedefined;            /* (S) */
    int lastlinedefined;        /* (S) */
    char short_src[LUA_IDSIZE]; /* (S) */
    /* private part */
    other fields
} lua_Debug;
```

A structure used to carry different pieces of information about an active function. `lua_getstack` (see lua_getstack()) fills only the private part of this structure, for later use. To fill the other fields of `lua_Debug` with useful information, call `lua_getinfo` (see lua_getinfo()).

The fields of `lua_Debug` have the following meaning:

- `source` If the function was defined in a string, then `source` is that string. If the function was defined in a file, then `source` starts with a `@` followed by the file name.
- `short_src` a "printable" version of `source`, to be used in error messages.
- `linedefined` the line number where the definition of the function starts.
- `lastlinedefined` the line number where the definition of the function ends.
- `what` the string `"Lua"` if the function is a Lua function, `"C"` if it is a C function, `"main"` if it is the main part of a chunk, and `"tail"` if it was a function that did a tail call. In the latter case, Lua has no other information about the function.
- `currentline` the current line where the given function is executing. When no line information is available, `currentline` is set to -1.
- `name` a reasonable name for the given function. Because functions in Lua are first-class values, they do not have a fixed name: some functions may be the value of multiple global variables, while others may be stored only in a table field. The `lua_getinfo` function checks how the function was called to find a suitable name. If it cannot find a name, then `name` is set to `NULL`.
- `namewhat` explains the `name` field. The value of `namewhat` can be `"global"`, `"local"`, `"method"`, `"field"`, `"upvalue"`, or `""` (the empty string), according to how the function was called. (Lua uses the empty string when no other option seems to apply.) `nups` the number of upvalues of the function.

lua_gethook

lua_gethook()

```
lua_Hook lua_gethook (lua_State *L);
```

Returns the current hook function.

lua_gethookcount

lua_gethookcount()

```
int lua_gethookcount (lua_State *L);
```

Returns the current hook count.

lua_gethookmask

lua_gethookmask()

```
int lua_gethookmask (lua_State *L);
```

Returns the current hook mask.

lua_getinfo

lua_getinfo()

```
int lua_getinfo (lua_State *L, const char *what, lua_Debug *ar);
```

Returns information about a specific function or function invocation.

To get information about a function invocation, the parameter `ar` must be a valid activation record that was filled by a previous call to `lua_getstack` (see lua_getstack()) or given as argument to a hook (see lua_Hook).

To get information about a function you push it onto the stack and start the `what` string with the character `>`. (In that case, `lua_getinfo` pops the function in the top of the stack.) For instance, to know in which line a function `f` was defined, you can write the following code:

```
lua_Debug ar;
lua_getfield(L, LUA_GLOBALSINDEX, "f");  /* get global 'f' */
lua_getinfo(L, ">S", &ar);
printf("%d\n", ar.linedefined);
```

Each character in the string `what` selects some fields of the structure `ar` to be filled or a value to be pushed on the stack:

`'n'` fills in the field `name` and `namewhat` `'S'` fills in the fields `source`, `short_src`, `linedefined`, `lastlinedefined`, and `what` `'l'` fills in the field `currentline` `'u'` fills in the field `nups` `'f'` pushes onto the stack the function that is running at the given level `'L'` pushes onto the stack a table whose indices are the numbers of the lines that are valid on the function. (A `valid line` is a line with some associated code, that is, a line where you can put a break point. Non-valid lines include empty lines and comments.)

This function returns 0 on error (for instance, an invalid option in `what`).

lua_getlocal

lua_getlocal()

```
const char *lua_getlocal (lua_State *L, lua_Debug *ar, int n);
```

Gets information about a local variable of a given activation record. The parameter `ar` must be a valid activation record that was filled by a previous call to `lua_getstack` (see lua_getstack()) or given as argument to a hook (see lua_Hook). The index `n` selects which local variable to inspect (1 is the first parameter or active local variable, and so on, until the last active local variable). `lua_getlocal` pushes the variable's value onto the stack and returns its name.

Variable names starting with `(` (open parentheses) represent internal variables (loop control variables, temporaries, and C function locals).

Returns `NULL` (and pushes nothing) when the index is greater than the number of active local variables.

lua_getstack lua_getstack()

```
int lua_getstack (lua_State *L, int level, lua_Debug *ar);
```

Gets information about the interpreter runtime stack.

This function fills parts of a `lua_Debug` (see lua_Debug) structure with an identification of the `activation record` of the function executing at a given level. Level 0 is the current running function, whereas level `n+1` is the function that has called level `n`. When there are no errors, `lua_getstack` returns 1; when called with a level greater than the stack depth, it returns 0.

lua_getupvalue lua_getupvalue()

```
const char *lua_getupvalue (lua_State *L, int funcindex, int n);
```

Gets information about a closure's upvalue. (For Lua functions, upvalues are the external local variables that the function uses, and that are consequently included in its closure.) `lua_getupvalue` gets the index `n` of an upvalue, pushes the upvalue's value onto the stack, and returns its name. `funcindex` points to the closure in the stack. (Upvalues have no particular order, as they are active through the whole function. So, they are numbered in an arbitrary order.)

Returns `NULL` (and pushes nothing) when the index is greater than the number of upvalues. For C functions, this function uses the empty string `""` as a name for all upvalues.

lua_Hook lua_Hook

```
typedef void (*lua_Hook) (lua_State *L, lua_Debug *ar);
```

Type for debugging hook functions.

Whenever a hook is called, its `ar` argument has its field `event` set to the specific event that triggered the hook. Lua identifies these events with the following constants: `LUA_HOOKCALL`, `LUA_HOOKRET`, `LUA_HOOKTAILRET`, `LUA_HOOKLINE`, and `LUA_HOOKCOUNT`. Moreover, for line events, the field `currentline` is also set. To get the value of any other field in `ar`, the hook must call `lua_getinfo` (see lua_getinfo()). For return events, `event` may be `LUA_HOOKRET`, the normal value, or `LUA_HOOKTAILRET`. In the latter case, Lua is simulating a return from a function that did a tail call; in this case, it is useless to call `lua_getinfo`.

While Lua is running a hook, it disables other calls to hooks. Therefore, if a hook calls back Lua to execute a function or a chunk, this execution occurs without any calls to hooks.

lua_sethook lua_sethook()

```
int lua_sethook (lua_State *L, lua_Hook f, int mask, int count);
```

Sets the debugging hook function.

Argument `f` is the hook function. `mask` specifies on which events the hook will be called: it is formed by a bitwise `or` of the constants `LUA_MASKCALL`, `LUA_MASKRET`, `LUA_MASKLINE`, and `LUA_MASKCOUNT`. The `count` argument is only meaningful when the mask includes `LUA_MASKCOUNT`. For each event, the hook is called as explained below:

- The `call hook`: is called when the interpreter calls a function. The hook is called just after Lua enters the new function, before the function gets its arguments.
- The `return hook`: is called when the interpreter returns from a function. The hook is called just before Lua leaves the function. You have no access to the values to be returned by the function.
- The `line hook`: is called when the interpreter is about to start the execution of a new line of code, or when it jumps back in the code (even to the same line). (This event only happens while Lua is executing a Lua function.)
- The `count hook`: is called after the interpreter executes every `count` instructions. (This event only happens while Lua is executing a Lua function.)

A hook is disabled by setting `mask` to zero.

lua_setlocal lua_setlocal()

```
const char *lua_setlocal (lua_State *L, lua_Debug *ar, int n);
```

Sets the value of a local variable of a given activation record. Parameters `ar` and `n` are as in `lua_getlocal` (see lua_getlocal()). `lua_setlocal` assigns the value at the top of the stack to the variable and returns its name. It also pops the value from the stack.

Returns `NULL` (and pops nothing) when the index is greater than the number of active local variables.

lua_setupvalue lua_setupvalue()

```
const char *lua_setupvalue (lua_State *L, int funcindex, int n);
```

Sets the value of a closure's upvalue. It assigns the value at the top of the stack to the upvalue and returns its name. It also pops the value from the stack. Parameters `funcindex` and `n` are as in the `lua_getupvalue` (see lua_getupvalue()).

Returns `NULL` (and pops nothing) when the index is greater than the number of upvalues.

lua-debugexample

As an example, the following function lists the names of all local variables and upvalues for a function at a given level of the stack:

```
int listvars (lua_State *L, int level) {
  lua_Debug ar;
  int i;
  const char *name;
  if (lua_getstack(L, level, &ar) == 0)
    return 0;  /* failure: no such level in the stack */
  i = 1;
  while ((name = lua_getlocal(L, &ar, i++)) != NULL) {
    printf("local %d %s\n", i-1, name);
    lua_pop(L, 1);  /* remove variable value */
  }
  lua_getinfo(L, "f", &ar);  /* retrieves function */
  i = 1;
  while ((name = lua_getupvalue(L, -1, i++)) != NULL) {
    printf("upvalue %d %s\n", i-1, name);
    lua_pop(L, 1);  /* remove upvalue value */
  }
  return 1;
}
```

4 THE AUXILIARY LIBRARY

lua-aux

The auxiliary library provides several convenient functions to interface C with Lua. While the basic API provides the primitive functions for all interactions between C and Lua, the auxiliary library provides higher-level functions for some common tasks.

All functions from the auxiliary library are defined in header file `lauxlib.h` and have a prefix `luaL_`.

All functions in the auxiliary library are built on top of the basic API, and so they provide nothing that cannot be done with this API.

Several functions in the auxiliary library are used to check C function arguments. Their names are always `luaL_check*` or `luaL_opt*`. All of these functions raise an error if the check is not satisfied. Because the error message is formatted for arguments (e.g., "bad argument #1"), you should not use these functions for other stack values.

4.1 Functions and Types

lua-auxFunctions

Here we list all functions and types from the auxiliary library in alphabetical order.

luaL_addchar

luaL_addchar()

```
void luaL_addchar (luaL_Buffer *B, char c);
```

Adds the character `c` to the buffer `B` (see luaL_Buffer).

luaL_addlstring

luaL_addlstring()

```
void luaL_addlstring (luaL_Buffer *B, const char *s, size_t l);
```

Adds the string pointed to by `s` with length `l` to the buffer `B` (see luaL_Buffer). The string may contain embedded zeros.

luaL_addsize

luaL_addsize()

```
void luaL_addsize (luaL_Buffer *B, size_t n);
```

Adds to the buffer `B` (see luaL_Buffer) a string of length `n` previously copied to the buffer area (see luaL_prepbuffer()).

luaL_addstring

luaL_addstring()

```
void luaL_addstring (luaL_Buffer *B, const char *s);
```

Adds the zero-terminated string pointed to by `s` to the buffer `B` (see luaL_Buffer). The string may not contain embedded zeros.

luaL_addvalue

luaL_addvalue()

```
void luaL_addvalue (luaL_Buffer *B);
```

Adds the value at the top of the stack to the buffer `B` (see luaL_Buffer). Pops the value.

This is the only function on string buffers that can (and must) be called with an extra element on the stack, which is the value to be added to the buffer.

luaL_argcheck

luaL_argcheck()

```
void luaL_argcheck (lua_State *L,
                    int cond,
                    int narg,
                    const char *extramsg);
```

Checks whether `cond` is true. If not, raises an error with the following message, where `func` is retrieved from the call stack:

```
bad argument #<narg> to <func> (<extramsg>)
```

luaL_argerror

luaL_argerror()

```
int luaL_argerror (lua_State *L, int narg, const char *extramsg);
```

Raises an error with the following message, where `func` is retrieved from the call stack:

```
bad argument #<narg> to <func> (<extramsg>)
```

This function never returns, but it is an idiom to use it in C functions as `return luaL_argerror( args )`.

luaL_Buffer luaL_Buffer

```
typedef struct luaL_Buffer luaL_Buffer;
```

Type for a `string buffer`.

A string buffer allows C code to build Lua strings piecemeal. Its pattern of use is as follows:

- First you declare a variable b of type `luaL_Buffer`.
- Then you initialize it with a call `luaL_buffinit(L, &b)` (see luaL_buffinit()).
- Then you add string pieces to the buffer calling any of the `luaL_add*` functions.
- You finish by calling `luaL_pushresult(&b)` (see luaL_pushresult()). This call leaves the final string on the top of the stack.

During its normal operation, a string buffer uses a variable number of stack slots. So, while using a buffer, you cannot assume that you know where the top of the stack is. You can use the stack between successive calls to buffer operations as long as that use is balanced; that is, when you call a buffer operation, the stack is at the same level it was immediately after the previous buffer operation. (The only exception to this rule is `luaL_addvalue` luaL_addvalue().) After calling `luaL_pushresult` the stack is back to its level when the buffer was initialized, plus the final string on its top.

luaL_buffinit luaL_buffinit()

```
void luaL_buffinit (lua_State *L, luaL_Buffer *B);
```

Initializes a buffer B. This function does not allocate any space; the buffer must be declared as a variable (see luaL_Buffer).

luaL_callmeta luaL_callmeta()

```
int luaL_callmeta (lua_State *L, int obj, const char *e);
```

Calls a metamethod.

If the object at index `obj` has a metatable and this metatable has a field `e`, this function calls this field and passes the object as its only argument. In this case this function returns 1 and pushes onto the stack the value returned by the call. If there is no metatable or no metamethod, this function returns 0 (without pushing any value on the stack).

luaL_checkany luaL_checkany()

```
void luaL_checkany (lua_State *L, int narg);
```

Checks whether the function has an argument of any type (including `nil`) at position `narg`.

luaL_checkint luaL_checkint()

```
int luaL_checkint (lua_State *L, int narg);
```

Checks whether the function argument `narg` is a number and returns this number cast to an `int`.

luaL_checkinteger luaL_checkinteger()

```
lua_Integer luaL_checkinteger (lua_State *L, int narg);
```

Checks whether the function argument `narg` is a number and returns this number cast to a `lua_Integer` (see lua_Integer).

luaL_checklong luaL_checklong()

```
long luaL_checklong (lua_State *L, int narg);
```

Checks whether the function argument `narg` is a number and returns this number cast to a `long`.

luaL_checklstring luaL_checklstring()

```
const char *luaL_checklstring (lua_State *L, int narg, size_t *l);
```

Checks whether the function argument `narg` is a string and returns this string; if `l` is not `NULL` fills `*l` with the string's length.

luaL_checknumber luaL_checknumber()

```
lua_Number luaL_checknumber (lua_State *L, int narg);
```

Checks whether the function argument `narg` is a number and returns this number (see lua_Number).

luaL_checkoption luaL_checkoption()

```
int luaL_checkoption (lua_State *L,
                      int narg,
                      const char *def,
                      const char *const lst[]);
```

Checks whether the function argument `narg` is a string and searches for this string in the array `lst` (which must be NULL-terminated). Returns the index in the array where the string was found. Raises an error if the argument is not a string or if the string cannot be found.

If `def` is not `NULL`, the function uses `def` as a default value when there is no argument `narg` or if this argument is `nil`.

This is a useful function for mapping strings to C enums. (The usual convention in Lua libraries is to use strings instead of numbers to select options.)

luaL_checkstack luaL_checkstack()

```
void luaL_checkstack (lua_State *L, int sz, const char *msg);
```

Grows the stack size to `top + sz` elements, raising an error if the stack cannot grow to that size. `msg` is an additional text to go into the error message.

luaL_checkstring luaL_checkstring()

```
const char *luaL_checkstring (lua_State *L, int narg);
```

Checks whether the function argument `narg` is a string and returns this string.

luaL_checktype luaL_checktype()

```
void luaL_checktype (lua_State *L, int narg, int t);
```

Checks whether the function argument `narg` has type `t` (see lua_type()).

luaL_checkudata luaL_checkudata()

```
void *luaL_checkudata (lua_State *L, int narg, const char *tname);
```

Checks whether the function argument `narg` is a userdata of the type `tname` (see luaL_newmetatable()).

luaL_dofile luaL_dofile()

```
int luaL_dofile (lua_State *L, const char *filename);
```

Loads and runs the given file. It is defined as the following macro:

```
(luaL_loadfile(L, filename) || lua_pcall(L, 0, LUA_MULTRET, 0))
```

It returns 0 if there are no errors or 1 in case of errors.

luaL_dostring luaL_dostring()

```
int luaL_dostring (lua_State *L, const char *str);
```

Loads and runs the given string. It is defined as the following macro:

```
(luaL_loadstring(L, str) || lua_pcall(L, 0, LUA_MULTRET, 0))
```

It returns 0 if there are no errors or 1 in case of errors.

luaL_error luaL_error()

```
int luaL_error (lua_State *L, const char *fmt, ...);
```

Raises an error. The error message format is given by `fmt` plus any extra arguments, following the same rules of `lua_pushfstring` (see lua_pushfstring()). It also adds at the beginning of the message the file name and the line number where the error occurred, if this information is available.

This function never returns, but it is an idiom to use it in C functions as `return luaL_error( args )`.

luaL_getmetafield luaL_getmetafield()

```
int luaL_getmetafield (lua_State *L, int obj, const char *e);
```

Pushes onto the stack the field `e` from the metatable of the object at index `obj`. If the object does not have a metatable, or if the metatable does not have this field, returns 0 and pushes nothing.

luaL_getmetatable luaL_getmetatable()

```
void luaL_getmetatable (lua_State *L, const char *tname);
```

Pushes onto the stack the metatable associated with name `tname` in the registry (see luaL_newmetatable()).

luaL_gsub luaL_gsub()

```
const char *luaL_gsub (lua_State *L,
                       const char *s,
                       const char *p,
                       const char *r);
```

Creates a copy of string `s` by replacing any occurrence of the string `p` with the string `r`. Pushes the resulting string on the stack and returns it.

luaL_loadbuffer luaL_loadbuffer()

```
int luaL_loadbuffer (lua_State *L,
                     const char *buff,
                     size_t sz,
                     const char *name);
```

Loads a buffer as a Lua chunk. This function uses `lua_load` (see lua_load()) to load the chunk in the buffer pointed to by `buff` with size `sz`.

This function returns the same results as `lua_load`. `name` is the chunk name, used for debug information and error messages.

luaL_loadfile luaL_loadfile()

```
int luaL_loadfile (lua_State *L, const char *filename);
```

Loads a file as a Lua chunk. This function uses `lua_load` (see lua_load()) to load the chunk in the file named `filename`. If `filename` is `NULL`, then it loads from the standard input. The first line in the file is ignored if it starts with a #.

This function returns the same results as `lua_load`, but it has an extra error code `LUA_ERRFILE` if it cannot open/read the file.

As `lua_load`, this function only loads the chunk; it does not run it.

luaL_loadstring luaL_loadstring()

```
int luaL_loadstring (lua_State *L, const char *s);
```

Loads a string as a Lua chunk. This function uses `lua_load` (see lua_load()) to load the chunk in the zero-terminated string `s`.

This function returns the same results as `lua_load`.

Also as `lua_load`, this function only loads the chunk; it does not run it.

luaL_newmetatable luaL_newmetatable()

```
int luaL_newmetatable (lua_State *L, const char *tname);
```

If the registry already has the key `tname`, returns 0. Otherwise, creates a new table to be used as a metatable for userdata, adds it to the registry with key `tname`, and returns 1.

In both cases pushes onto the stack the final value associated with `tname` in the registry.

luaL_newstate luaL_newstate()

```
lua_State *luaL_newstate (void);
```

Creates a new Lua state. It calls `lua_newstate` (see lua_newstate()) with an allocator based on the standard C `realloc` function and then sets a panic function (see lua_atpanic()) that prints an error message to the standard error output in case of fatal errors.

Returns the new state, or `NULL` if there is a memory allocation error.

luaL_openlibs luaL_openlibs()

```
void luaL_openlibs (lua_State *L);
```

Opens all standard Lua libraries into the given state. See also lua-openlibs for details on how to open individual libraries.

luaL_optint luaL_optint()

```
int luaL_optint (lua_State *L, int narg, int d);
```

If the function argument `narg` is a number, returns this number cast to an `int`. If this argument is absent or is `nil`, returns `d`. Otherwise, raises an error.

luaL_optinteger luaL_optinteger()

```
lua_Integer luaL_optinteger (lua_State *L,
                             int narg,
                             lua_Integer d);
```

If the function argument `narg` is a number, returns this number cast to a `lua_Integer` (see lua_Integer). If this argument is absent or is `nil`, returns `d`. Otherwise, raises an error.

luaL_optlong luaL_optlong()

```
long luaL_optlong (lua_State *L, int narg, long d);
```

If the function argument `narg` is a number, returns this number cast to a `long`. If this argument is absent or is `nil`, returns `d`. Otherwise, raises an error.

luaL_optlstring luaL_optlstring()

```
const char *luaL_optlstring (lua_State *L,
                             int narg,
                             const char *d,
                             size_t *l);
```

If the function argument `narg` is a string, returns this string. If this argument is absent or is `nil`, returns `d`. Otherwise, raises an error.

If `l` is not `NULL`, fills the position `*l` with the results' length.

luaL_optnumber luaL_optnumber()

```
lua_Number luaL_optnumber (lua_State *L, int narg, lua_Number d);
```

If the function argument `narg` is a number, returns this number. If this argument is absent or is `nil`, returns `d`. Otherwise, raises an error.

luaL_optstring luaL_optstring()

```
const char *luaL_optstring (lua_State *L,
                            int narg,
                            const char *d);
```

If the function argument `narg` is a string, returns this string. If this argument is absent or is `nil`, returns `d`. Otherwise, raises an error.

luaL_prepbuffer luaL_prepbuffer()

```
char *luaL_prepbuffer (luaL_Buffer *B);
```

Returns an address to a space of size `LUAL_BUFFERSIZE` where you can copy a string to be added to buffer `B` (see luaL_Buffer). After copying the string into this space you must call `luaL_addsize` (see luaL_addsize()) with the size of the string to actually add it to the buffer.

luaL_pushresult luaL_pushresult()

```
void luaL_pushresult (luaL_Buffer *B);
```

Finishes the use of buffer B leaving the final string on the top of the stack.

luaL_ref luaL_ref()

```
int luaL_ref (lua_State *L, int t);
```

Creates and returns a `reference`, in the table at index `t`, for the object at the top of the stack (and pops the object).

A reference is a unique integer key. As long as you do not manually add integer keys into table `t`, `luaL_ref` ensures the uniqueness of the key it returns. You can retrieve an object referred by reference `r` by calling `lua_rawgeti(L, t, r)` (see lua_rawgeti()). Function `luaL_unref` (see luaL_unref()) frees a reference and its associated object.

If the object at the top of the stack is `nil`, `luaL_ref` returns the constant `LUA_REFNIL`. The constant `LUA_NOREF` is guaranteed to be different from any reference returned by `luaL_ref`.

luaL_Reg luaL_Reg

```
typedef struct luaL_Reg {
    const char *name;
    lua_CFunction func;
} luaL_Reg;
```

Type for arrays of functions to be registered by `luaL_register` (see luaL_register()). `name` is the function name and `func` is a pointer to the function. Any array of `luaL_Reg` must end with a sentinel entry in which both `name` and `func` are `NULL`.

luaL_register luaL_register()

```
void luaL_register (lua_State *L,
                    const char *libname,
                    const luaL_Reg *l);
```

Opens a library.

When called with `libname` equal to `NULL`, it simply registers all functions in the list `l` (see luaL_Reg) into the table on the top of the stack.

When called with a non-null `libname`, `luaL_register` creates a new table `t`, sets it as the value of the global variable `libname`, sets it as the value of `package.loaded[libname]`, and registers on it all functions in the list `l`. If there is a table in `package.loaded[libname]` or in variable `libname`, reuses this table instead of creating a new one.

In any case the function leaves the table on the top of the stack.

luaL_typename luaL_typename()

```
const char *luaL_typename (lua_State *L, int idx);
```

Returns the name of the type of the value at index `idx`.

luaL_typerror luaL_typerror()

```
int luaL_typerror (lua_State *L, int narg, const char *tname);
```

Generates an error with a message like the following:

`location : bad argument narg to 'func' ( tname expected, got rt )`

where `location` is produced by `luaL_where` (see luaL_where()), `func` is the name of the current function, and `rt` is the type name of the actual argument.

luaL_unref luaL_unref()

```
void luaL_unref (lua_State *L, int t, int ref);
```

Releases reference `ref` from the table at index `t` (see luaL_ref()). The entry is removed from the table, so that the referred object can be collected. The reference `ref` is also freed to be used again.

If `ref` is `LUA_NOREF` or `LUA_REFNIL`, `luaL_unref` does nothing.

luaL_where luaL_where()

```
void luaL_where (lua_State *L, int lvl);
```

Pushes onto the stack a string identifying the current position of the control at level `lvl` in the call stack. Typically this string has the following format:

`chunkname:currentline:`

Level 0 is the running function, level 1 is the function that called the running function, etc.

This function is used to build a prefix for error messages.

5 STANDARD LIBRARIES lua-lib

The standard libraries provide useful functions that are implemented directly through the C API. Some of these functions provide essential services to the language (e.g., `type` and `getmetatable`); others provide access to "outside" services (e.g., I/O); and others could be implemented in Lua itself, but are quite useful or have critical performance requirements that deserve an implementation in C (e.g., `sort`).

All libraries are implemented through the official C API and are provided as separate C modules. Currently, Lua has the following standard libraries:

- basic library;
- package library;
- string manipulation;
- table manipulation;
- mathematical functions (sin, log, etc.);
- input and output;
- operating system facilities;
- debug facilities.

Except for the basic and package libraries, each library provides all its functions as fields of a global table or as methods of its objects.

lua-openlibs

To have access to these libraries, the C host program should call the `luaL_openlibs` function, which opens all standard libraries (see luaL_openlibs()). Alternatively, the host program can open the libraries individually by calling `luaopen_base` (for the basic library), `luaopen_package` (for the package library), `luaopen_string` (for the string library), `luaopen_table` (for the table library), `luaopen_math` (for the mathematical library), `luaopen_io` (for the I/O and the Operating System libraries), and `luaopen_debug` (for the debug library). These functions are declared in `lualib.h` and should not be called directly: you must call them like any other Lua C function, e.g., by using `lua_call` (see lua_call()).

5.1 Basic Functions

lua-lib-core

The basic library provides some core functions to Lua. If you do not include this library in your application, you should check carefully whether you need to provide implementations for some of its facilities.

assert({v} [, {message}])
assert()
Issues an error when the value of its argument v is false (i.e., `nil` or `false`); otherwise, returns all its arguments. `message` is an error message; when absent, it defaults to "assertion failed!"

collectgarbage({opt} [, {arg}])
collectgarbage()
This function is a generic interface to the garbage collector. It performs different functions according to its first argument, {opt}:

`"stop"` stops the garbage collector. `"restart"` restarts the garbage collector. `"collect"` performs a full garbage-collection cycle. `"count"` returns the total memory in use by Lua (in Kbytes). `"step"` performs a garbage-collection step. The step "size" is controlled by {arg} (larger values mean more steps) in a non-specified way. If you want to control the step size you must experimentally tune the value of {arg}. Returns `true` if the step finished a collection cycle. `"setpause"` sets {arg} /100 as the new value for the `pause` of the collector (see lua-gc). `"setstepmul"` sets {arg} /100 as the new value for the `step multiplier` of the collector (see lua-gc).

dofile({filename})
dofile()
Opens the named file and executes its contents as a Lua chunk. When called without arguments, `dofile` executes the contents of the standard input (`stdin`). Returns all values returned by the chunk. In case of errors, `dofile` propagates the error to its caller (that is, `dofile` does not run in protected mode).

error({message} [, {level}])
error()
Terminates the last protected function called and returns `message` as the error message. Function {error} never returns.

Usually, {error} adds some information about the error position at the beginning of the message. The {level} argument specifies how to get the error position. With level 1 (the default), the error position is where the {error} function was called. Level 2 points the error to where the function that called {error} was called; and so on. Passing a level 0 avoids the addition of error position information to the message.

_G
_G
A global variable (not a function) that holds the global environment (that is, `_G._G = _G`). Lua itself does not use this variable; changing its value does not affect any environment, nor vice-versa. (Use `setfenv` to change environments.)

getfenv({f})
getfenv()
Returns the current environment in use by the function. {f} can be a Lua function or a number that specifies the function at that stack level: Level 1 is the function calling `getfenv`. If the given function is not a Lua function, or if {f} is 0, `getfenv` returns the global environment. The default for {f} is 1.

getmetatable({object})
getmetatable()
If {object} does not have a metatable, returns `nil`. Otherwise, if the object's metatable has a `"__metatable"` field, returns the associated value. Otherwise, returns the metatable of the given object.

ipairs({t})
ipairs()
Returns three values: an iterator function, the table {t}, and 0, so that the construction

```
for i,v in ipairs(t) do body end
```

will iterate over the pairs `(1,t[1])`, `(2,t[2])`, ..., up to the first integer key absent from the table.

load({func} [, {chunkname}])
load()
Loads a chunk using function {func} to get its pieces. Each call to {func} must return a string that concatenates with previous results. A return of `nil` (or no value) signals the end of the chunk.

If there are no errors, returns the compiled chunk as a function; otherwise, returns `nil` plus the error message. The environment of the returned function is the global environment.

{chunkname} is used as the chunk name for error messages and debug information.

loadfile([{filename}])
loadfile()
Similar to `load` (see load()), but gets the chunk from file {filename} or from the standard input, if no file name is given.

loadstring({string} [, {chunkname}])
loadstring()
Similar to `load` (see load()), but gets the chunk from the given {string}.

To load and run a given string, use the idiom

```
assert(loadstring(s))()
```

next({table} [, {index}]) next()
Allows a program to traverse all fields of a table. Its first argument is a table and its second argument is an index in this table. next returns the next index of the table and its associated value. When called with nil as its second argument, next returns an initial index and its associated value. When called with the last index, or with nil in an empty table, next returns nil. If the second argument is absent, then it is interpreted as nil. In particular, you can use next(t) to check whether a table is empty.

The order in which the indices are enumerated is not specified, even for numeric indices. (To traverse a table in numeric order, use a numerical for or the ipairs() function.)

The behavior of next is undefined if, during the traversal, you assign any value to a non-existent field in the table. You may however modify existing fields. In particular, you may clear existing fields.

pairs({t}) pairs()
Returns three values: the next() function, the table {t}, and nil, so that the construction

```
for k,v in pairs(t) do body end
```

will iterate over all key-value pairs of table {t}.

pcall({f}, {arg1}, {...}) pcall()
Calls function {f} with the given arguments in protected mode. This means that any error inside {f} is not propagated; instead, pcall catches the error and returns a status code. Its first result is the status code (a boolean), which is true if the call succeeds without errors. In such case, pcall also returns all results from the call, after this first result. In case of any error, pcall returns false plus the error message.

print({...}) print()
Receives any number of arguments, and prints their values to stdout, using the tostring tostring() function to convert them to strings. print is not intended for formatted output, but only as a quick way to show a value, typically for debugging. For formatted output, use string.format (see string.format()).

rawequal({v1}, {v2}) rawequal()
Checks whether {v1} is equal to {v2}, without invoking any metamethod. Returns a boolean.

rawget({table}, {index}) rawget()
Gets the real value of table[index], without invoking any metamethod. {table} must be a table; {index} may be any value.

rawset({table}, {index}, {value}) rawset()
Sets the real value of table[index] to {value}, without invoking any metamethod. {table} must be a table, {index} any value different from nil, and {value} any Lua value.

This function returns {table}.

select({index}, {...}) select()
If {index} is a number, returns all arguments after argument number {index}. Otherwise, {index} must be the string "#", and select returns the total number of extra arguments it received.

setfenv({f}, {table}) setfenv()
Sets the environment to be used by the given function. {f} can be a Lua function or a number that specifies the function at that stack level: Level 1 is the function calling setfenv. setfenv returns the given function.

As a special case, when {f} is 0 setfenv changes the environment of the running thread. In this case, setfenv returns no values.

setmetatable({table}, {metatable}) setmetatable()
Sets the metatable for the given table. (You cannot change the metatable of other types from Lua, only from C.) If {metatable} is nil, removes the metatable of the given table. If the original metatable has a "__metatable" field, raises an error.

This function returns {table}.

tonumber({e} [, {base}]) tonumber()
Tries to convert its argument to a number. If the argument is already a number or a string convertible to a number, then tonumber returns this number; otherwise, it returns nil.

An optional argument specifies the base to interpret the numeral. The base may be any integer between 2 and 36, inclusive. In bases above 10, the letter A (in either upper or lower case) represents 10, B represents 11, and so forth, with Z' representing 35. In base 10 (the default), the number may have a decimal part, as well as an optional exponent part (see lua-lexical). In other bases, only unsigned integers are accepted.

tostring({e}) tostring()
Receives an argument of any type and converts it to a string in a reasonable format. For complete control of how numbers are converted, use string.format (see string.format()).

__tostring
If the metatable of {e} has a "__tostring" field, tostring calls the corresponding value with {e} as argument, and uses the result of the call as its result.

type({v}) lua-type()
Returns the type of its only argument, coded as a string. The possible results of this function are "nil" (a string, not the value nil), "number", "string", "boolean", "table", "function", "thread", and "userdata".

unpack({list} [, {i} [, {j}]]) unpack()
Returns the elements from the given table. This function is equivalent to

```
return list[i], list[i+1], ..., list[j]
```

except that the above code can be written only for a fixed number of elements. By default, {i} is 1 and {j} is the length of the list, as defined by the length operator (see lua-length).

_VERSION _VERSION
A global variable (not a function) that holds a string containing the current interpreter version. The current contents of this string is "Lua 5.1"

.

xpcall({f}, {err}) xpcall()
This function is similar to pcall (see pcall()), except that you can set a new error handler.

xpcall calls function {f} in protected mode, using {err} as the error handler. Any error inside {f} is not propagated; instead, xpcall catches the error, calls the {err} function with the original error object, and returns a status code. Its first result is the status code (a boolean), which is true if the call succeeds without errors. In this case, xpcall also returns all results from the call, after this first result. In case of any error, xpcall returns false plus the result from {err}.

5.2 Coroutine Manipulation lua-lib-coroutine

The operations related to coroutines comprise a sub-library of the basic library and come inside the table coroutine. See lua-coroutine for a general description of coroutines.

coroutine.create({f}) coroutine.create()
Creates a new coroutine, with body {f}. {f} must be a Lua function. Returns this new coroutine, an object with type "thread".

coroutine.resume({co} [, {val1}, {...}]) coroutine.resume()
Starts or continues the execution of coroutine {co}. The first time you resume a coroutine, it starts running its body. The values {val1}, {...} are passed as arguments to the body function. If the coroutine has yielded, resume restarts it; the values {val1}, {...} are passed as the results from the yield.

If the coroutine runs without any errors, resume returns true plus any values passed to yield (if the coroutine yields) or any values returned by the body function(if the coroutine terminates). If there is any error, resume returns false plus the error message.

coroutine.running() coroutine.running()
Returns the running coroutine, or nil when called by the main thread.

coroutine.status({co}) coroutine.status()
Returns the status of coroutine {co}, as a string: "running", if the coroutine is running (that is, it called status); "suspended", if the coroutine is suspended in a call to yield, or if it has not started running yet; "normal" if the coroutine is active but not running (that is, it has resumed another coroutine); and "dead" if the coroutine has finished its body function, or if it has stopped with an error.

coroutine.wrap({f}) coroutine.wrap()
Creates a new coroutine, with body {f}. {f} must be a Lua function. Returns a function that resumes the coroutine each time it is called. Any arguments passed to the function behave as the extra arguments to resume. Returns the same values returned by resume, except the first boolean. In case of error, propagates the error.

coroutine.yield({...}) coroutine.yield()
Suspends the execution of the calling coroutine. The coroutine cannot be running a C function, a metamethod, or an iterator. Any arguments to yield are passed as extra results to resume.

5.3 Modules lua-modules

The package library provides basic facilities for loading and building modules in Lua. It exports two of its functions directly in the global environment: require and module (see require() and module()). Everything else is exported in a table package.

module({name} [, {...}]) module()
Creates a module. If there is a table in package.loaded[name], this table is the module. Otherwise, if there is a global table t with the given name, this table is the module. Otherwise creates a new table t and sets it as the value of the global {name} and the value of package.loaded[name]. This function also initializes t._NAME with the given name, t._M with the module (t itself), and t._PACKAGE with the package name (the full module name minus last component; see below). Finally, module sets t as the new environment of the current function and the new value of package.loaded[name], so that require() returns t.

If {name} is a compound name (that is, one with components separated by dots), module creates (or reuses, if they already exist) tables for each component. For instance, if {name} is a.b.c, then module stores the module table in field c of field b of global a.

This function may receive optional options after the module name, where each option is a function to be applied over the module.

require({modname}) require()
Loads the given module. The function starts by looking into the package.loaded table to determine whether {modname} is already loaded. If it is, then require returns the value stored at package.loaded[modname]. Otherwise, it tries to find a loader for the module.

To find a loader, first require queries package.preload[modname]. If it has a value, this value (which should be a function) is the loader. Otherwise require searches for a Lua loader using the path stored in package.path. If that also fails, it searches for a C loader using the path stored in package.cpath. If that also fails, it tries an all-in-one loader (see below).

When loading a C library, require first uses a dynamic link facility to link the application with the library. Then it tries to find a C function inside this library to be used as the loader. The name of this C function is the string "luaopen_" concatenated with a copy of the module name where each dot is replaced by an underscore. Moreover, if the module name has a hyphen, its prefix up to (and including) the first hyphen is removed. For instance, if the module name is a.v1-b.c, the function name will be luaopen_b_c.

If require finds neither a Lua library nor a C library for a module, it calls the all-in-one loader. This loader searches the C path for a library for the root name of the given module. For instance, when requiring a.b.c, it will search for a C library for a. If found, it looks into it for an open function for the submodule; in our example, that would be luaopen_a_b_c. With this facility, a package can pack several C submodules into one single library, with each submodule keeping its original open function.

Once a loader is found, require calls the loader with a single argument, {modname}. If the loader returns any value, require assigns the returned value to package.loaded[modname]. If the loader returns no value and has not assigned any value to package.loaded[modname], then require assigns true to this entry. In any case, require returns the final value of package.loaded[modname].

If there is any error loading or running the module, or if it cannot find any loader for the module, then require signals an error.

package.cpath package.cpath
The path used by require to search for a C loader.

Lua initializes the C path `package.cpath` in the same way it initializes the Lua path `package.path`, using the environment variable `LUA_CPATH` (plus another default path defined in `luaconf.h`).

package.loaded package.loaded
A table used by `require` to control which modules are already loaded. When you require a module `modname` and `package.loaded[modname]` is not false, `require` simply returns the value stored there.

package.loadlib({libname}, {funcname}) package.loadlib()
Dynamically links the host program with the C library {libname}. Inside this library, looks for a function {funcname} and returns this function as a C function. (So, {funcname} must follow the protocol (see lua_CFunction)).

This is a low-level function. It completely bypasses the package and module system. Unlike `require`, it does not perform any path searching and does not automatically adds extensions. {libname} must be the complete file name of the C library, including if necessary a path and extension. {funcname} must be the exact name exported by the C library (which may depend on the C compiler and linker used).

This function is not supported by ANSI C. As such, it is only available on some platforms (Windows, Linux, Mac OS X, Solaris, BSD, plus other Unix systems that support the `dlfcn` standard).

package.path package.path
The path used by `require` to search for a Lua loader.

At start-up, Lua initializes this variable with the value of the environment variable `LUA_PATH` or with a default path defined in `luaconf.h`, if the environment variable is not defined. Any `";;"` in the value of the environment variable is replaced by the default path.

A path is a sequence of `templates` separated by semicolons. For each template, `require` will change each interrogation mark in the template by `filename`, which is `modname` with each dot replaced by a "directory separator" (such as `"/"` in Unix); then it will try to load the resulting file name. So, for instance, if the Lua path is

```
"./?.lua;./?.lc;/usr/local/?/init.lua"
```

the search for a Lua loader for module `foo` will try to load the files `./foo.lua`, `./foo.lc`, and `/usr/local/foo/init.lua`, in that order.

package.preload package.preload
A table to store loaders for specific modules (see require()).

package.seeall({module}) package.seeall()
Sets a metatable for {module} with its `__index` field referring to the global environment, so that this module inherits values from the global environment. To be used as an option to function {module}.

5.4 String Manipulation lua-lib-string

This library provides generic functions for string manipulation, such as finding and extracting substrings, and pattern matching. When indexing a string in Lua, the first character is at position 1 (not at 0, as in C). Indices are allowed to be negative and are interpreted as indexing backwards, from the end of the string. Thus, the last character is at position -1, and so on.

The string library provides all its functions inside the table `string`. It also sets a metatable for strings where the `__index` field points to the `string` table. Therefore, you can use the string functions in object-oriented style. For instance, `string.byte(s, i)` can be written as `s:byte(i)`.

string.byte({s} [, {i} [, {j}]]) string.byte()
Returns the internal numerical codes of the characters `s[i]`, `s[i+1]`,..., `s[j]`. The default value for {i} is 1; the default value for {j} is {i}.

Note that numerical codes are not necessarily portable across platforms.

string.char({...}) string.char()
Receives zero or more integers. Returns a string with length equal to the number of arguments, in which each character has the internal numerical code equal to its correspondent argument.

Note that numerical codes are not necessarily portable across platforms.

string.dump({function}) string.dump()
Returns a string containing a binary representation of the given function, so that a later loadstring() on this string returns a copy of the function. {function} must be a Lua function without upvalues.

string.find({s}, {pattern} [, {init} [, {plain}]]) string.find()
Looks for the first match of {pattern} in the string {s}. If it finds a match, then {find} returns the indices of {s} where this occurrence starts and ends; otherwise, it returns `nil`. A third, optional numerical argument {init} specifies where to start the search; its default value is 1 and may be negative. A value of {true} as a fourth, optional argument {plain} turns off the pattern matching facilities, so the function does a plain "find substring" operation, with no characters in {pattern} being considered "magic". Note that if {plain} is given, then {init} must be given as well.

If the pattern has captures, then in a successful match the captured values are also returned, after the two indices.

string.format({formatstring}, {...}) string.format()
Returns a formatted version of its variable number of arguments following the description given in its first argument (which must be a string). The format string follows the same rules as the `printf` family of standard C functions. The only differences are that the options/modifiers `*`, `l`, `L`, `n`, `p`, and `h` are not supported and that there is an extra option, `q`. The `q` option formats a string in a form suitable to be safely read back by the Lua interpreter: the string is written between double quotes, and all double quotes, newlines, embedded zeros, and backslashes in the string are correctly escaped when written. For instance, the call

```
string.format('%q', 'a string with "quotes" and \n new line')
```

will produce the string:

```
"a string with \"quotes\" and \
 new line"
```

The options `c`, `d`, `E`, `e`, `f`, `g`, `G`, `i`, `o`, `u`, `X`, and `x` all expect a number as argument, whereas `q` and `s` expect a string.

This function does not accept string values containing embedded zeros.

string.gmatch({s}, {pattern}) string.gmatch()
Returns an iterator function that, each time it is called, returns the next captures from {pattern} over string {s}.

If {pattern} specifies no captures, then the whole match is produced in each call.

As an example, the following loop

```
s = "hello world from Lua"
for w in string.gmatch(s, "%a+") do
  print(w)
end
```

will iterate over all the words from string {s}, printing one per line. The next example collects all pairs key=value from the given string into a table:

```
t = {}
s = "from=world, to=Lua"
for k, v in string.gmatch(s, "(%w+)=(%w+)") do
  t[k] = v
end
```

string.gsub({s}, {pattern}, {repl} [, {n}]) string.gsub()
Returns a copy of {s} in which all occurrences of the {pattern} have been replaced by a replacement string specified by {repl}, which may be a string, a table, or a function. gsub also returns, as its second value, the total number of substitutions made.

If {repl} is a string, then its value is used for replacement. The character % works as an escape character: any sequence in {repl} of the form %n, with {n} between 1 and 9, stands for the value of the {n} -th captured substring (see below). The sequence %0 stands for the whole match. The sequence %% stands for a single %.

If {repl} is a table, then the table is queried for every match, using the first capture as the key; if the pattern specifies no captures, then the whole match is used as the key.

If {repl} is a function, then this function is called every time a match occurs, with all captured substrings passed as arguments, in order; if the pattern specifies no captures, then the whole match is passed as a sole argument.

If the value returned by the table query or by the function call is a string or a number, then it is used as the replacement string; otherwise, if it is false or nil, then there is no replacement (that is, the original match is kept in the string).

The optional last parameter {n} limits the maximum number of substitutions to occur. For instance, when {n} is 1 only the first occurrence of pattern is replaced.

Here are some examples:

```
x = string.gsub("hello world", "(%w+)", "%1 %1")
--> x="hello hello world world"

x = string.gsub("hello world", "%w+", "%0 %0", 1)
--> x="hello hello world"

x = string.gsub("hello world from Lua", "(%w+)%s*(%w+)", "%2 %1")
--> x="world hello Lua from"

x = string.gsub("home = $HOME, user = $USER", "%$(%w+)", os.getenv)
--> x="home = /home/roberto, user = roberto"

x = string.gsub("4+5 = $return 4+5$", "%$(.-)%$", function (s)
      return loadstring(s)()
    end)
--> x="4+5 = 9"

local t = {name="lua", version="5.1"}
x = string.gsub("$name%-$version.tar.gz", "%$(%w+)", t)
--> x="lua-5.1.tar.gz"
```

string.len({s}) string.len()
Receives a string and returns its length. The empty string "" has length 0. Embedded zeros are counted, so "a\000b\000c" has length 5.

string.lower({s}) string.lower()
Receives a string and returns a copy of this string with all uppercase letters changed to lowercase. All other characters are left unchanged. The definition of what an uppercase letter is depends on the current locale.

string.match({s}, {pattern} [, {init}]) string.match()
Looks for the first match of {pattern} in the string {s}. If it finds one, then match returns the captures from the pattern; otherwise it returns nil. If {pattern} specifies no captures, then the whole match is returned. A third, optional numerical argument {init} specifies where to start the search; its default value is 1 and may be negative.

string.rep({s}, {n}) string.rep()
Returns a string that is the concatenation of {n} copies of the string {s}.

string.reverse({s}) string.reverse()
Returns a string that is the string {s} reversed.

string.sub({s}, {i} [, {j}]) string.sub()
Returns the substring of {s} that starts at {i} and continues until {j}; {i} and {j} may be negative. If {j} is absent, then it is assumed to be equal to -1 (which is the same as the string length). In particular, the call string.sub(s,1,j) returns a prefix of {s} with length {j}, and string.sub(s,-i) returns a suffix of {s} with length {i}.

string.upper({s}) string.upper()
Receives a string and returns a copy of that string with all lowercase letters changed to uppercase. All other characters are left unchanged. The definition of what a lowercase letter is depends on the current locale.

5.4.1 Patterns lua-pattern

A character class is used to represent a set of characters. The following combinations are allowed in describing a character class:

- x (where x is not one of the magic characters `^$()%.[]*+-?`) represents the character x itself.
- `.` (a dot) represents all characters.
- `%a` represents all letters.
- `%c` represents all control characters.
- `%d` represents all digits.
- `%l` represents all lowercase letters.
- `%p` represents all punctuation characters.
- `%s` represents all space characters.
- `%u` represents all uppercase letters.
- `%w` represents all alphanumeric characters.
- `%x` represents all hexadecimal digits.
- `%z` represents the character with representation `0`.
- `%x` (where x is any non-alphanumeric character) represents the character x. This is the standard way to escape the magic characters. Any punctuation character (even the non-magic) can be preceded by a `%` when used to represent itself in a pattern.
- `[set]` represents the class which is the union of all characters in `set`. A range of characters may be specified by separating the end characters of the range with a `-`. All classes `%x` described above may also be used as components in `set`. All other characters in `set` represent themselves. For example, `[%w_]` (or `[_%w]`) represents all alphanumeric characters plus the underscore, `[0-7]` represents the octal digits, and `[0-7%l%-]` represents the octal digits plus the lowercase letters plus the `-` character.

The interaction between ranges and classes is not defined. Therefore, patterns like `[%a-z]` or `[a-%%]` have no meaning.

- `[^set]` represents the complement of `set`, where `set` is interpreted as above.

For all classes represented by single letters (`%a`, `%c`, etc.), the corresponding uppercase letter represents the complement of the class. For instance, `%S` represents all non-space characters.

The definitions of letter, space, and other character groups depend on the current locale. In particular, the class `[a-z]` may not be equivalent to `%l`.

PATTERN ITEM lua-patternitem

A pattern item may be

- a single character class, which matches any single character in the class;
- a single character class followed by *, which matches 0 or more repetitions of characters in the class. These repetition items will always match the longest possible sequence;
- a single character class followed by +, which matches 1 or more repetitions of characters in the class. These repetition items will always match the longest possible sequence; lua-nongreedy
- a single character class followed by `-`, which also matches 0 or more repetitions of characters in the class. Unlike *, these repetition items will always match the shortest possible sequence;
- a single character class followed by ?, which matches 0 or 1 occurrences of a character in the class;
- `%n`, for n between 1 and 9; such item matches a substring equal to the n -th captured string (see below);
- `%bxy`, where x and y are two distinct characters; such item matches strings that start with x, end with y, and where the x and y are balanced. This means that, if one reads the string from left to right, counting +1 for an x and -1 for a y, the ending y is the first y where the count reaches 0. For instance, the item `%b()` matches expressions with balanced parentheses.

PATTERN

A pattern is a sequence of pattern items. A ^ at the beginning of a pattern anchors the match at the beginning of the subject string. A $ at the end of a pattern anchors the match at the end of the subject string. At other positions, ^ and $ have no special meaning and represent themselves.

CAPTURES lua-capture

A pattern may contain sub-patterns enclosed in parentheses; they describe captures. When a match succeeds, the substrings of the subject string that match captures are stored (captured) for future use. Captures are numbered according to their left parentheses. For instance, in the pattern `"(a*(.)%w(%s*))"`, the part of the string matching `"a*(.)%w(%s*)"` is stored as the first capture (and therefore has number 1); the character matching `.` is captured with number 2, and the part matching `%s*` has number 3.

As a special case, the empty capture `()` captures the current string position (a number). For instance, if we apply the pattern `"()aa()"` on the string `"flaaap"`, there will be two captures: 3 and 5.

A pattern cannot contain embedded zeros. Use `%z` instead.

5.5 Table Manipulation lua-lib-table

This library provides generic functions for table manipulation. It provides all its functions inside the table `table`.

Most functions in the table library assume that the table represents an array or a list. For those functions, when we talk about the "length" of a table we mean the result of the length operator.

table.concat({table} [, {sep} [, {i} [, {j}]]]) table.concat()
Given an array where all elements are strings or numbers, returns `table[i]..sep..table[i+1] ... sep..table[j]`. The default value for `{sep}` is the empty string, the default for `{i}` is 1, and the default for `{j}` is the length of the table. If `{i}` is greater than `{j}`, returns the empty string.

table.foreach({table}, {f}) table.foreach()
Executes the given {f} over all elements of {table}. For each element, {f} is called with the index and respective value as arguments. If {f} returns a non-`nil` value, then the loop is broken, and this value is returned as the final value of table.foreach.

See next() for extra information about table traversals.

table.foreachi({table}, {f}) table.foreachi()
Executes the given {f} over the numerical indices of {table}. For each index, {f} is called with the index and respective value as arguments. Indices are visited in sequential order, from 1 to n, where n is the length of the table. If {f} returns a non-`nil` value, then the loop is broken and this value is returned as the result of table.foreachi.

table.insert({table}, [{pos},] {value}) table.insert()
Inserts element {value} at position {pos} in {table}, shifting up other elements to open space, if necessary. The default value for {pos} is n+1, where n is the length of the table (see lua-length), so that a call table.insert(t,x) inserts x at the end of table t.

table.maxn({table}) table.maxn()
Returns the largest positive numerical index of the given table, or zero if the table has no positive numerical indices. (To do its job this function does a linear traversal of the whole table.)

table.remove({table} [, {pos}]) table.remove()
Removes from {table} the element at position {pos}, shifting down other elements to close the space, if necessary. Returns the value of the removed element. The default value for {pos} is n, where n is the length of the table (see lua-length), so that a call table.remove(t) removes the last element of table t.

table.sort({table} [, {comp}]) table.sort()
Sorts table elements in a given order, in-place, from table[1] to table[n], where n is the length of the table (see lua-length). If {comp} is given, then it must be a function that receives two table elements, and returns true when the first is less than the second (so that not comp(a[i+1],a[i]) will be true after the sort). If {comp} is not given, then the standard Lua operator < is used instead.

The sort algorithm is not stable, that is, elements considered equal by the given order may have their relative positions changed by the sort.

5.6 Mathematical Functions lua-lib-math

This library is an interface to most of the functions of the standard C math library. It provides all its functions inside the table math.

math.abs({x}) math.abs()
Returns the absolute value of {x}.

math.acos({x}) math.acos()
Returns the arc cosine of {x} (in radians).

math.asin({x}) math.asin()
Returns the arc sine of {x} (in radians).

math.atan({x}) math.atan()
Returns the arc tangent of {x} (in radians).

math.atan2({x}, {y}) math.atan2()
Returns the arc tangent of x/y (in radians), but uses the signs of both parameters to find the quadrant of the result. (It also handles correctly the case of {y} being zero.)

math.ceil({x}) math.ceil()
Returns the smallest integer larger than or equal to {x}.

math.cos({x}) math.cos()
Returns the cosine of {x} (assumed to be in radians).

math.cosh({x}) math.cosh()
Returns the hyperbolic cosine of {x}.

math.deg({x}) math.deg()
Returns the angle {x} (given in radians) in degrees.

math.exp({x}) math.exp()
Returns the value e^x.

math.floor({x}) math.floor()
Returns the largest integer smaller than or equal to {x}.

math.fmod({x}, {y}) math.fmod()
Returns the remainder of the division of {x} by {y}.

math.frexp({x}) math.frexp()
Returns m and e such that x = m * 2^e, e is an integer and the absolute value of m is in the range [0.5, 1) (or zero when {x} is zero).

math.huge math.huge
The value HUGE_VAL, a value larger than or equal to any other numerical value.

math.ldexp({m}, {e}) math.ldexp()
Returns m * 2^e (e should be an integer).

math.log({x}) math.log()
Returns the natural logarithm of {x}.

math.log10({x}) math.log10()
Returns the base-10 logarithm of {x}.

math.max({x}, {...}) math.max()
Returns the maximum value among its arguments.

math.min({x}, {...}) math.min()
Returns the minimum value among its arguments.

math.modf({x}) math.modf()
Returns two numbers, the integral part of {x} and the fractional part of {x}.

math.pi math.pi
The value of pi.

math.pow({x}, {y}) math.pow()
Returns x^y. (You can also use the expression x^y to compute this value.)

math.rad({x}) math.rad()
Returns the angle {x} (given in degrees) in radians.

math.random([{m} [, {n}]]) math.random()
This function is an interface to the simple pseudo-random generator function rand provided by ANSI C. (No guarantees can be given for its statistical properties.)

When called without arguments, returns a pseudo-random real number in the range [0,1). When called with a number {m}, math.random returns a pseudo-random integer in the range [1, m]. When called with two numbers {m} and {n}, math.random returns a pseudo-random integer in the range [m, n].

math.randomseed({x}) math.randomseed()
Sets {x} as the "seed" for the pseudo-random generator: equal seeds produce equal sequences of numbers.

math.sin({x}) math.sin()
Returns the sine of {x} (assumed to be in radians).

math.sinh({x}) math.sinh()
Returns the hyperbolic sine of {x}.

math.sqrt({x}) math.sqrt()
Returns the square root of {x}. (You can also use the expression x^0.5 to compute this value.)

math.tan({x}) math.tan()
Returns the tangent of {x} (assumed to be in radians).

math.tanh({x}) math.tanh()
Returns the hyperbolic tangent of {x}.

5.6 Input and Output Facilities lua-lib-io

The I/O library provides two different styles for file manipulation. The first one uses implicit file descriptors; that is, there are operations to set a default input file and a default output file, and all input/output operations are over these default files. The second style uses explicit file descriptors.

When using implicit file descriptors, all operations are supplied by table io. When using explicit file descriptors, the operation io.open returns a file descriptor and then all operations are supplied as methods of the file descriptor.

The table io also provides three predefined file descriptors with their usual meanings from C: io.stdin, io.stdout, and io.stderr.

Unless otherwise stated, all I/O functions return nil on failure (plus an error message as a second result) and some value different from nil on success.

io.close([{file}]) io.close()
Equivalent to file:close. Without a {file}, closes the default output file.

io.flush() io.flush()
Equivalent to file:flush over the default output file.

io.input([{file}]) io.input()
When called with a file name, it opens the named file (in text mode), and sets its handle as the default input file. When called with a file handle, it simply sets this file handle as the default input file. When called without parameters, it returns the current default input file.

In case of errors this function raises the error, instead of returning an error code.

io.lines([{filename}]) io.lines()
Opens the given file name in read mode and returns an iterator function that, each time it is called, returns a new line from the file. Therefore, the construction

```
for line in io.lines(filename) do body end
```

will iterate over all lines of the file. When the iterator function detects the end of file, it returns nil (to finish the loop) and automatically closes the file.

The call io.lines() (without a file name) is equivalent to io.input():lines(); that is, it iterates over the lines of the default input file. In this case it does not close the file when the loop ends.

io.open({filename} [, {mode}]) io.open()
This function opens a file, in the mode specified in the string {mode}. It returns a new file handle, or, in case of errors, nil plus an error message.

The {mode} string can be any of the following:

- "r" read mode (the default);
- "w" write mode;
- "a" append mode;
- "r+" update mode, all previous data is preserved;
- "w+" update mode, all previous data is erased;
- "a+" append update mode, previous data is preserved, writing is only allowed at the end of file.

The {mode} string may also have a b at the end, which is needed in some systems to open the file in binary mode. This string is exactly what is used in the standard C function fopen.

io.output([{file}]) io.output()
Similar to io.input, but operates over the default output file.

io.popen({prog} [, {mode}]) io.popen()
Starts program {prog} in a separated process and returns a file handle that you can use to read data from this program (if {mode} is "r", the default) or to write data to this program (if {mode} is "w").

This function is system dependent and is not available on all platforms.

io.read({...}) io.read()
Equivalent to io.input():read.

io.tmpfile() io.tmpfile()
Returns a handle for a temporary file. This file is opened in update mode and it is automatically removed when the program ends.

io.type({obj}) io.type()
Checks whether {obj} is a valid file handle. Returns the string "file" if {obj} is an open file handle, "closed file" if {obj} is a closed file handle, or nil if {obj} is not a file handle.

io.write({...}) io.write()
Equivalent to io.output():write.

file:close() file:close()
Closes file. Note that files are automatically closed when their handles are garbage collected, but that takes an unpredictable amount of time to happen.

file:flush() file:flush()
Saves any written data to file.

file:lines() file:lines()
Returns an iterator function that, each time it is called, returns a new line from the file. Therefore, the construction

```
for line in file:lines() do body end
```

will iterate over all lines of the file. (Unlike io.lines, this function does not close the file when the loop ends.)

file:read({...}) file:read()
Reads the file file, according to the given formats, which specify what to read. For each format, the function returns a string (or a number) with the characters read, or nil if it cannot read data with the specified format. When called without formats, it uses a default format that reads the entire next line (see below).

The available formats are

"*n" reads a number; this is the only format that returns a number instead of a string. "*a" reads the whole file, starting at the current position. On end of file, it returns the empty string. "*l" reads the next line (skipping the end of line), returning nil on end of file. This is the default format. number reads a string with up to that number of characters, returning nil on end of file. If number is zero, it reads nothing and returns an empty string, or nil on end of file.

file:seek([{whence}] [, {offset}]) file:seek()
Sets and gets the file position, measured from the beginning of the file, to the position given by {offset} plus a base specified by the string {whence}, as follows:

- "set": base is position 0 (beginning of the file);
- "cur": base is current position;
- "end": base is end of file;

In case of success, function seek returns the final file position, measured in bytes from the beginning of the file. If this function fails, it returns nil, plus a string describing the error.

The default value for {whence} is "cur", and for {offset} is 0. Therefore, the call file:seek() returns the current file position, without changing it; the call file:seek("set") sets the position to the beginning of the file (and returns 0); and the call file:seek("end") sets the position to the end of the file, and returns its size.

file:setvbuf({mode} [, {size}]) file:setvbuf()
Sets the buffering mode for an output file. There are three available modes:

"no" no buffering; the result of any output operation appears immediately. "full" full buffering; output operation is performed only when the buffer is full (or when you explicitly flush the file (see io.flush()). "line" line buffering; output is buffered until a newline is output or there is any input from some special files (such as a terminal device).

For the last two cases, {size} specifies the size of the buffer, in bytes. The default is an appropriate size.

file:write({...}) file:write()
Writes the value of each of its arguments to file. The arguments must be strings or numbers. To write other values, use tostring tostring() or string.format string.format() before write.

5.8 Operating System Facilities lua-lib-os

This library is implemented through table os.

os.clock() os.clock()
Returns an approximation of the amount in seconds of CPU time used by the program.

os.date([{format} [, {time}]]) os.date()
Returns a string or a table containing date and time, formatted according to the given string {format}.

If the {time} argument is present, this is the time to be formatted (see the os.time function os.time() for a description of this value). Otherwise, date formats the current time.

If {format} starts with !, then the date is formatted in Coordinated Universal Time. After this optional character, if {format} is the string "*t", then date returns a table with the following fields: year (four digits), month (1-12), day (1-31), hour (0-23), min (0-59), sec (0-61), wday (weekday, Sunday is 1), yday (day of the year), and isdst (daylight saving flag, a boolean).

If {format} is not "*t", then date returns the date as a string, formatted according to the same rules as the C function strftime.

When called without arguments, date returns a reasonable date and time representation that depends on the host system and on the current locale (that is, os.date() is equivalent to os.date("%c")).

os.difftime({t2}, {t1}) os.difftime()
Returns the number of seconds from time {t1} to time {t2}. In POSIX, Windows, and some other systems, this value is exactly t2 - t1 .

os.execute([{command}]) os.execute()
This function is equivalent to the C function system. It passes {command} to be executed by an operating system shell. It returns a status code, which is system-dependent. If {command} is absent, then it returns nonzero if a shell is available and zero otherwise.

os.exit([{code}]) os.exit()
Calls the C function exit, with an optional {code}, to terminate the host program. The default value for {code} is the success code.

os.getenv({varname}) os.getenv()
Returns the value of the process environment variable {varname}, or nil if the variable is not defined.

os.remove({filename}) os.remove()
Deletes the file with the given name. Directories must be empty to be removed. If this function fails, it returns nil, plus a string describing the error.

os.rename({oldname}, {newname}) os.rename()
Renames file named {oldname} to {newname}. If this function fails, it returns nil, plus a string describing the error.

os.setlocale({locale} [, {category}]) os.setlocale()
Sets the current locale of the program. {locale} is a string specifying a locale; {category} is an optional string describing which category to change: "all", "collate", "ctype", "monetary", "numeric", or "time"; the default category is "all". The function returns the name of the new locale, or nil if the request cannot be honored.

os.time([{table}]) os.time()
Returns the current time when called without arguments, or a time representing the date and time specified by the given table. This table must have fields year, month, and day, and may have fields hour, min, sec, and isdst (for a description of these fields, see the os.date function os.date()).

The returned value is a number, whose meaning depends on your system. In POSIX, Windows, and some other systems, this number counts the number of seconds since some given start time (the "epoch"). In other systems, the meaning is not specified, and the number returned by time can be used only as an argument to date and difftime.

os.tmpname() os.tmpname()
Returns a string with a file name that can be used for a temporary file. The file must be explicitly opened before its use and explicitly removed when no longer needed.

5.9 The Debug Library lua-lib-debug

This library provides the functionality of the debug interface to Lua programs. You should exert care when using this library. The functions provided here should be used exclusively for debugging and similar tasks, such as profiling. Please resist the temptation to use them as a usual programming tool: they can be very slow. Moreover, several of its functions violate some assumptions about Lua code (e.g., that variables local to a function cannot be accessed from outside or that userdata metatables cannot be changed by Lua code) and therefore can compromise otherwise secure code.

All functions in this library are provided inside the debug table. All functions that operate over a thread have an optional first argument which is the thread to operate over. The default is always the current thread.

debug.debug() debug.debug()
Enters an interactive mode with the user, running each string that the user enters. Using simple commands and other debug facilities, the user can inspect global and local variables, change their values, evaluate expressions, and so on. A line containing only the word cont finishes this function, so that the caller continues its execution.

Note that commands for debug.debug are not lexically nested within any function, and so have no direct access to local variables.

debug.getfenv(o) debug.getfenv()
Returns the environment of object {o}.

debug.gethook([{thread}]) debug.gethook()
Returns the current hook settings of the thread, as three values: the current hook function, the current hook mask, and the current hook count (as set by the debug.sethook function).

debug.getinfo([{thread},] {function} [, {what}]) debug.getinfo()
Returns a table with information about a function. You can give the function directly, or you can give a number as the value of {function}, which means the function running at level {function} of the call stack of the given thread: level 0 is the current function (getinfo itself); level 1 is the function that called getinfo; and so on. If {function} is a number larger than the number of active functions, then getinfo returns nil.

The returned table may contain all the fields returned by lua_getinfo (see lua_getinfo()), with the string {what} describing which fields to fill in. The default for {what} is to get all information available, except the table of valid lines. If present, the option f adds a field named func with the function itself. If present, the option L adds a field named activelines with the table of valid lines.

For instance, the expression debug.getinfo(1,"n").name returns the name of the current function, if a reasonable name can be found, and debug.getinfo(print) returns a table with all available information about the print function.

debug.getlocal([{thread},] {level}, {local}) debug.getlocal()
This function returns the name and the value of the local variable with index {local} of the function at level {level} of the stack. (The first parameter or local variable has index 1, and so on, until the last active local variable.) The function returns nil if there is no local variable

with the given index, and raises an error when called with a {level} out of range. (You can call debug.getinfo debug.getinfo() to check whether the level is valid.)

Variable names starting with ((open parentheses) represent internal variables (loop control variables, temporaries, and C function locals).

debug.getmetatable({object}) debug.getmetatable()
Returns the metatable of the given {object} or nil if it does not have a metatable.

debug.getregistry() debug.getregistry()
Returns the registry table (see lua-registry).

debug.getupvalue({func}, {up}) debug.getupvalue()
This function returns the name and the value of the upvalue with index {up} of the function {func}. The function returns nil if there is no upvalue with the given index.

debug.setfenv({object}, {table}) debug.setfenv()
Sets the environment of the given {object} to the given {table}. Returns {object}.

debug.sethook([{thread},] {hook}, {mask} [, {count}]) debug.sethook()
Sets the given function as a hook. The string {mask} and the number {count} describe when the hook will be called. The string mask may have the following characters, with the given meaning:

- "c" : The hook is called every time Lua calls a function;
- "r" : The hook is called every time Lua returns from a function;
- "l" : The hook is called every time Lua enters a new line of code.

With a {count} different from zero, the hook is called after every {count} instructions.

When called without arguments, the debug.sethook turns off the hook.

When the hook is called, its first parameter is a string describing the event that triggered its call: "call", "return" (or "tail return"), "line", and "count". For line events, the hook also gets the new line number as its second parameter. Inside a hook, you can call getinfo with level 2 to get more information about the running function (level 0 is the getinfo function, and level 1 is the hook function), unless the event is "tail return". In this case, Lua is only simulating the return, and a call to getinfo will return invalid data.

debug.setlocal([{thread},] {level}, {local}, {value}) debug.setlocal()
This function assigns the value {value} to the local variable with index {local} of the function at level {level} of the stack. The function returns nil if there is no local variable with the given index, and raises an error when called with a {level} out of range. (You can call getinfo to check whether the level is valid.) Otherwise, it returns the name of the local variable.

debug.setmetatable({object}, {table}) debug.setmetatable()
Sets the metatable for the given {object} to the given {table} (which can be nil).

debug.setupvalue({func}, {up}, {value}) debug.setupvalue()
This function assigns the value {value} to the upvalue with index {up} of the function {func}. The function returns nil if there is no upvalue with the given index. Otherwise, it returns the name of the upvalue.

debug.traceback([{thread},] [{message} [,{level}]]) debug.traceback()
Returns a string with a traceback of the call stack. An optional {message} string is appended at the beginning of the traceback. An optional {level} number tells at which level to start the traceback (default is 1, the function calling traceback).

C LUAREF DOC

lua-ref-doc

This is a Vim help file containing a reference for Lua 5.1, and it is -- with a few exceptions and adaptations -- a copy of the Lua 5.1 Reference Manual (see lua-ref-bibliography). For usage information, refer to lua-ref-doc. For copyright information, see lua-ref-copyright.

The main ideas and concepts on how to implement this reference were taken from Christian Habermann's CRefVim project (https://www.vim.org/scripts/script.php?script_id=614).

Adapted for bundled Nvim documentation; the original plugin can be found at https://www.vim.org/scripts/script.php?script_id=1291

LUV REFERENCE MANUAL

This file documents the Lua bindings for the LibUV library which is used for Nvim's event-loop and is accessible from Lua via vim.uv (e.g., uv.version() is exposed as vim.uv.version()).

For information about this manual, see luv-credits.

For further examples, see https://github.com/luvit/luv/tree/master/examples.

INTRODUCTION

luv luv-intro uv

The luv (https://github.com/luvit/luv) project provides access to the multi-platform support library libuv (https://github.com/libuv/libuv) in Lua code. It was primarily developed for the luvit (https://github.com/luvit/luvit) project as the built-in uv module, but can be used in other Lua environments.

More information about the core libuv library can be found at the original libuv documentation page (https://docs.libuv.org/).

TCP Echo Server Example

Here is a small example showing a TCP echo server:

```
local uv = vim.uv

local server = uv.new_tcp()
assert(server:bind("127.0.0.1", 1337))
server:listen(128, function (err)
  assert(not err, err)
  local client = uv.new_tcp()
  server:accept(client)
  client:read_start(function (err, chunk)
    assert(not err, err)
    if chunk then
      client:write(chunk)
    else
      client:shutdown()
      client:close()
    end
  end)
end)
print("TCP server listening at 127.0.0.1 port 1337")
uv.run() -- an explicit run call is necessary outside of luvit
```

Module Layout

The luv library contains a single Lua module referred to hereafter as uv for simplicity. This module consists mostly of functions with names corresponding to their original libuv versions. For example, the libuv function uv_tcp_bind has a luv version at uv.tcp_bind(). Currently, only two non-function fields exists: uv.constants and uv.errno, which are tables.

Functions vs Methods

In addition to having simple functions, luv provides an optional method-style API. For example, uv.tcp_bind(server, host, port) can alternatively be called as server:bind(host, port) . Note that the first argument server becomes the object and tcp_ is removed from the function name. Method forms are documented below where they exist.

Synchronous vs Asynchronous Functions

Functions that accept a callback are asynchronous. These functions may immediately return results to the caller to indicate their initial status, but their final execution is deferred until at least the next libuv loop iteration. After completion, their callbacks are executed with any results passed to it.

Functions that do not accept a callback are synchronous. These functions immediately return their results to the caller.

Some (generally FS and DNS) functions can behave either synchronously or asynchronously. If a callback is provided to these functions, they behave asynchronously; if no callback is provided, they behave synchronously.

Pseudo-Types

Some unique types are defined. These are not actual types in Lua, but they are used here to facilitate documenting consistent behavior:

- fail: an assertable nil, string, string tuple (see luv-error-handling)
- callable: a function; or a table or userdata with a __call metamethod
- buffer: a string or a sequential table of strings
- threadargs: variable arguments (...) of type nil, boolean, number, string, or userdata; number of arguments limited to 9.

CONTENTS

luv-contents

This documentation is mostly a retelling of the libuv API documentation (https://docs.libuv.org/en/v1.x/api.html) within the context of luv's Lua API. Low-level implementation details and unexposed C functions and types are not documented here except for when they are relevant to behavior seen in the Lua module.

CONSTANTS

luv-constants

As a Lua library, luv supports and encourages the use of lowercase strings to represent options. For example:

```
-- signal start with string input
uv.signal_start("sigterm", function(signame)
  print(signame) -- string output: "sigterm"
end)
```

However, luv also superficially exposes libuv constants in a Lua table at uv.constants where its keys are uppercase constant names and their associated values are integers defined internally by libuv. The values from this table may be supported as function arguments, but their use may not change the output type. For example:

```
-- signal start with integer input
uv.signal_start(uv.constants.SIGTERM, function(signame)
  print(signame) -- string output: "sigterm"
end)
```

The uppercase constants defined in uv.constants that have associated lowercase option strings are listed below.

Address Families

- AF_UNIX: "unix"
- AF_INET: "inet"
- AF_INET6: "inet6"
- AF_IPX: "ipx"
- AF_NETLINK: "netlink"
- AF_X25: "x25"
- AF_AX25: "as25"
- AF_ATMPVC: "atmpvc"
- AF_APPLETALK: "appletalk"
- AF_PACKET: "packet"

Signals

- SIGHUP: "sighup"
- SIGINT: "sigint"
- SIGQUIT: "sigquit"
- SIGILL: "sigill"
- SIGTRAP: "sigtrap"
- SIGABRT: "sigabrt"
- SIGIOT: "sigiot"
- SIGBUS: "sigbus"
- SIGFPE: "sigfpe"
- SIGKILL: "sigkill"
- SIGUSR1: "sigusr1"

- SIGSEGV: "sigsegv"
- SIGUSR2: "sigusr2"
- SIGPIPE: "sigpipe"
- SIGALRM: "sigalrm"
- SIGTERM: "sigterm"
- SIGCHLD: "sigchld"
- SIGSTKFLT: "sigstkflt"
- SIGCONT: "sigcont"
- SIGSTOP: "sigstop"
- SIGTSTP: "sigtstp"
- SIGBREAK: "sigbreak"
- SIGTTIN: "sigttin"
- SIGTTOU: "sigttou"
- SIGURG: "sigurg"
- SIGXCPU: "sigxcpu"
- SIGXFSZ: "sigxfsz"
- SIGVTALRM: "sigvtalrm"
- SIGPROF: "sigprof"
- SIGWINCH: "sigwinch"
- SIGIO: "sigio"
- SIGPOLL: "sigpoll"
- SIGLOST: "siglost"
- SIGPWR: "sigpwr"
- SIGSYS: "sigsys"

Socket Types

- SOCK_STREAM: "stream"
- SOCK_DGRAM: "dgram"
- SOCK_SEQPACKET: "seqpacket"
- SOCK_RAW: "raw"
- SOCK_RDM: "rdm"

TTY Modes

- TTY_MODE_NORMAL: "normal"
- TTY_MODE_RAW: "raw"
- TTY_MODE_IO: "io"

TTY_MODE_RAW_VT: "raw_vt"

FS Modification Times

- FS_UTIME_NOW: "now"
- FS_UTIME_OMIT: "omit"

ERROR HANDLING

luv-error-handling

In libuv, errors are represented by negative numbered constants. While these constants are made available in the uv.errno table, they are not returned by luv functions and the libuv functions used to handle them are not exposed. Instead, if an internal error is encountered, the failing luv function will return to the caller an assertable nil, err, name tuple:

- nil idiomatically indicates failure
- err is a string with the format {name}: {message}
  - {name} is the error name provided internally by uv_err_name
  - {message} is a human-readable message provided internally by uv_strerror
- name is the same string used to construct err

This tuple is referred to below as the fail pseudo-type.

When a function is called successfully, it will return either a value that is relevant to the operation of the function, or the integer 0 to indicate success, or sometimes nothing at all. These cases are documented below.

uv.errno

uv.errno

Below is a list of known error names and error strings. See Libuv's "Error constants" page for further details. (https://docs.libuv.org/en/v1.x/errors.html#error-constants)

- E2BIG: argument list too long.
- EACCES: permission denied.
- EADDRINUSE: address already in use.
- EADDRNOTAVAIL: address not available.
- EAFNOSUPPORT: address family not supported.
- EAGAIN: resource temporarily unavailable.
- EAI_ADDRFAMILY: address family not supported.
- EAI_AGAIN: temporary failure.
- EAI_BADFLAGS: bad ai_flags value.
- EAI_BADHINTS: invalid value for hints.
- EAI_CANCELED: request canceled.
- EAI_FAIL: permanent failure.

- EAI_FAMILY: ai_family not supported.
- EAI_MEMORY: out of memory.
- EAI_NODATA: no address.
- EAI_NONAME: unknown node or service.
- EAI_OVERFLOW: argument buffer overflow.
- EAI_PROTOCOL: resolved protocol is unknown.
- EAI_SERVICE: service not available for socket type.
- EAI_SOCKTYPE: socket type not supported.
- EALREADY: connection already in progress.
- EBADF: bad file descriptor.
- EBUSY: resource busy or locked.
- ECANCELED: operation canceled.
- ECHARSET: invalid Unicode character.
- ECONNABORTED: software caused connection abort.
- ECONNREFUSED: connection refused.
- ECONNRESET: connection reset by peer.
- EDESTADDRREQ: destination address required.
- EEXIST: file already exists.
- EFAULT: bad address in system call argument.
- EFBIG: file too large.
- EHOSTUNREACH: host is unreachable.
- EINTR: interrupted system call.
- EINVAL: invalid argument.
- EIO: i/o error.
- EISCONN: socket is already connected.
- EISDIR: illegal operation on a directory.
- ELOOP: too many symbolic links encountered.
- EMFILE: too many open files.
- EMSGSIZE: message too long.
- ENAMETOOLONG: name too long.

- ENETDOWN: network is down.
- ENETUNREACH: network is unreachable.
- ENFILE: file table overflow.
- ENOBUFS: no buffer space available.
- ENODEV: no such device.
- ENOENT: no such file or directory.
- ENOMEM: not enough memory.
- ENONET: machine is not on the network.
- ENOPROTOOPT: protocol not available.
- ENOSPC: no space left on device.
- ENOSYS: function not implemented.
- ENOTCONN: socket is not connected.
- ENOTDIR: not a directory.
- ENOTEMPTY: directory not empty.
- ENOTSOCK: socket operation on non-socket.
- ENOTSUP: operation not supported on socket.
- EOVERFLOW: value too large for defined data type.
- EPERM: operation not permitted.
- EPIPE: broken pipe.
- EPROTO: protocol error.
- EPROTONOSUPPORT: protocol not supported.
- EPROTOTYPE: protocol wrong type for socket.
- ERANGE: result too large.
- EROFS: read-only file system.
- ESHUTDOWN: cannot send after transport endpoint shutdown.
- ESPIPE: invalid seek.
- ESRCH: no such process.
- ETIMEDOUT: connection timed out.
- ETXTBSY: text file is busy.
- EXDEV: cross-device link not permitted.

- UNKNOWN: unknown error.
- EOF: end of file.
- ENXIO: no such device or address.
- EMLINK: too many links.
- ENOTTY: inappropriate ioctl for device.
- EFTYPE: inappropriate file type or format.
- EILSEQ: illegal byte sequence.
- ESOCKTNOSUPPORT: socket type not supported.

VERSION CHECKING

luv-version-checking

uv.version()

uv.version()

Returns the libuv version packed into a single integer. 8 bits are used for each component, with the patch number stored in the 8 least significant bits. For example, this would be 0x010203 in libuv 1.2.3.

Returns: integer

uv.version_string()

uv.version_string()

Returns the libuv version number as a string. For example, this would be "1.2.3" in libuv 1.2.3. For non-release versions, the version suffix is included.

Returns: string

uv_loop_t — Event loop

luv-event-loop uv_loop_t

The event loop is the central part of libuv's functionality. It takes care of polling for I/O and scheduling callbacks to be run based on different sources of events.

In luv, there is an implicit uv loop for every Lua state that loads the library. You can use this library in an multi-threaded environment as long as each thread has it's own Lua state with its corresponding own uv loop. This loop is not directly exposed to users in the Lua module.

uv.loop_close()

uv.loop_close()

Closes all internal loop resources. In normal execution, the loop will automatically be closed when it is garbage collected by Lua, so it is not necessary to explicitly call loop_close(). Call this function only after the loop has finished executing and all open handles and requests have been closed, or it will return EBUSY.

Returns: 0 or fail

uv.run([{mode}])

uv.run()

Parameters:

- mode: string or nil (default: "default")

This function runs the event loop. It will act differently depending on the specified mode:

- "default": Runs the event loop until there are no more active and referenced handles or requests. Returns true if uv.stop() was called and there are still active handles or requests. Returns false in all other cases.
- "once": Poll for I/O once. Note that this function blocks if there are no pending callbacks. Returns false when done (no active handles or requests left), or true if more callbacks are expected (meaning you should run the event loop again sometime in the future).
- "nowait": Poll for I/O once but don't block if there are no pending callbacks. Returns false if done (no active handles or requests left), or true if more callbacks are expected (meaning you should run the event loop again sometime in the future).

Returns: boolean or fail

Note: Luvit will implicitly call uv.run() after loading user code, but if you use the luv bindings directly, you need to call this after registering your initial set of event callbacks to start the event loop.

uv.loop_configure({option}, {...}) uv.loop_configure()

Parameters:

- option: string
- ...: depends on option, see below

Set additional loop options. You should normally call this before the first call to uv_run() unless mentioned otherwise.

Supported options:

- "block_signal": Block a signal when polling for new events. The second argument to loop_configure() is the signal name (as a lowercase string) or the signal number. This operation is currently only implemented for "sigprof" signals, to suppress unnecessary wakeups when using a sampling profiler. Requesting other signals will fail with EINVAL.
- "metrics_idle_time": Accumulate the amount of idle time the event loop spends in the event provider. This option is necessary to use metrics_idle_time().

An example of a valid call to this function is:

```
uv.loop_configure("block_signal", "sigprof")
```

Returns: 0 or fail

Note: Be prepared to handle the ENOSYS error; it means the loop option is not supported by the platform.

uv.loop_mode() uv.loop_mode()

If the loop is running, returns a string indicating the mode in use. If the loop is not running, nil is returned instead.

Returns: string or nil

uv.loop_alive() uv.loop_alive()

Returns true if there are referenced active handles, active requests, or closing handles in the loop; otherwise, false.

Returns: boolean or fail

uv.stop() uv.stop()

Stop the event loop, causing uv.run() to end as soon as possible. This will happen not sooner than the next loop iteration. If this function was called before blocking for I/O, the loop won't block for I/O on this iteration.

Returns: Nothing.

uv.backend_fd() uv.backend_fd()

Get backend file descriptor. Only kqueue, epoll, and event ports are supported.

This can be used in conjunction with uv.run("nowait") to poll in one thread and run the event loop's callbacks in another

Returns: integer or nil

Note: Embedding a kqueue fd in another kqueue pollset doesn't work on all platforms. It's not an error to add the fd but it never generates events.

uv.backend_timeout() uv.backend_timeout()

Get the poll timeout. The return value is in milliseconds, or -1 for no timeout.

Returns: integer

uv.now() uv.now()

Returns the current timestamp in milliseconds. The timestamp is cached at the start of the event loop tick, see uv.update_time() for details and rationale.

The timestamp increases monotonically from some arbitrary point in time. Don't make assumptions about the starting point, you will only get disappointed.

Returns: integer

Note: Use uv.hrtime() if you need sub-millisecond granularity.

uv.update_time() uv.update_time()

Update the event loop's concept of "now". Libuv caches the current time at the start of the event loop tick in order to reduce the number of time-related system calls.

You won't normally need to call this function unless you have callbacks that block the event loop for longer periods of time, where "longer" is somewhat subjective but probably on the order of a millisecond or more.

Returns: Nothing.

uv.walk({callback}) uv.walk()

Parameters:

- callback: callable
    - handle: userdata for sub-type of uv_handle_t

Walk the list of handles: callback will be executed with each handle.

Returns: Nothing.

```
-- Example usage of uv.walk to close all handles that
-- aren't already closing.
uv.walk(function (handle)
  if not handle:is_closing() then
    handle:close()
  end
end)
```

uv_req_t — Base request

luv-base-request uv_req_t

uv_req_t is the base type for all libuv request types.

uv.cancel({req}) uv.cancel()

> method form req:cancel()

Parameters:

- req: userdata for sub-type of uv_req_t

Cancel a pending request. Fails if the request is executing or has finished executing. Only cancellation of uv_fs_t, uv_getaddrinfo_t, uv_getnameinfo_t and uv_work_t requests is currently supported.

Returns: 0 or fail

uv.req_get_type({req}) uv.req_get_type()

> method form req:get_type()

Parameters:

- req: userdata for sub-type of uv_req_t

Returns the name of the struct for a given request (e.g. "fs" for uv_fs_t) and the libuv enum integer for the request's type (uv_req_type).

Returns: string, integer

uv_handle_t — Base handle

luv-base-handle uv_handle_t

uv_handle_t is the base type for all libuv handle types. All API functions defined here work with any handle type.

uv.is_active({handle}) uv.is_active()

> method form handle:is_active()

Parameters:

- handle: userdata for sub-type of uv_handle_t

Returns true if the handle is active, false if it's inactive. What "active" means depends on the type of handle:

- A uv_async_t handle is always active and cannot be deactivated, except by closing it with uv.close().
- A uv_pipe_t, uv_tcp_t, uv_udp_t, etc. handle - basically any handle that deals with I/O - is active when it is doing something that involves I/O, like reading, writing, connecting, accepting new connections, etc.
- A uv_check_t, uv_idle_t, uv_timer_t, etc. handle is active when it has been started with a call

to uv.check_start(), uv.idle_start(), uv.timer_start() etc. until it has been stopped with a call to its respective stop function.

Returns: boolean or fail

uv.is_closing({handle}) uv.is_closing()

> method form handle:is_closing()

Parameters:

- handle: userdata for sub-type of uv_handle_t

Returns true if the handle is closing or closed, false otherwise.

Returns: boolean or fail

Note: This function should only be used between the initialization of the handle and the arrival of the close callback.

uv.close({handle} [, {callback}]) uv.close()

> method form handle:close([callback])

Parameters:

- handle: userdata for sub-type of uv_handle_t
- callback: callable or nil

Request handle to be closed. callback will be called asynchronously after this call. This MUST be called on each handle before memory is released.

Handles that wrap file descriptors are closed immediately but callback will still be deferred to the next iteration of the event loop. It gives you a chance to free up any resources associated with the handle.

In-progress requests, like uv_connect_t or uv_write_t, are cancelled and have their callbacks called asynchronously with ECANCELED.

Returns: Nothing.

uv.ref({handle}) uv.ref()

> method form handle:ref()

Parameters:

- handle: userdata for sub-type of uv_handle_t

Reference the given handle. References are idempotent, that is, if a handle is already referenced calling this function again will have no effect.

Returns: Nothing.

See luv-reference-counting.

uv.unref({handle}) uv.unref()

> method form handle:unref()

Parameters:

- handle: userdata for sub-type of uv_handle_t

Un-reference the given handle. References are idempotent, that is, if a handle is not referenced calling this function again will have no effect.

Returns: Nothing.

See luv-reference-counting.

uv.has_ref({handle}) uv.has_ref()

> method form handle:has_ref()

Parameters:

- handle: userdata for sub-type of uv_handle_t

Returns true if the handle referenced, false if not.

Returns: boolean or fail

See luv-reference-counting.

uv.send_buffer_size({handle} [, {size}]) uv.send_buffer_size()

> method form handle:send_buffer_size([size])

Parameters:

- handle: userdata for sub-type of uv_handle_t
- size: integer or nil (default: 0)

Gets or sets the size of the send buffer that the operating system uses for the socket.

If size is omitted (or 0), this will return the current send buffer size; otherwise, this will use size to set the new send buffer size.

This function works for TCP, pipe and UDP handles on Unix and for TCP and UDP handles on Windows.

Returns:

- integer or fail (if size is nil or 0)
- 0 or fail (if size is not nil and not 0)

Note: Linux will set double the size and return double the size of the original set value.

uv.recv_buffer_size({handle} [, {size}]) uv.recv_buffer_size()

> method form handle:recv_buffer_size([size])

Parameters:

- handle: userdata for sub-type of uv_handle_t
- size: integer or nil (default: 0)

Gets or sets the size of the receive buffer that the operating system uses for the socket.

If size is omitted (or 0), this will return the current send buffer size; otherwise, this will use size to set the new send buffer size.

This function works for TCP, pipe and UDP handles on Unix and for TCP and UDP handles on Windows.

Returns:

- integer or fail (if size is nil or 0)
- 0 or fail (if size is not nil and not 0)

Note: Linux will set double the size and return double the size of the original set value.

uv.fileno({handle}) uv.fileno()

> method form handle:fileno()

Parameters:

- handle: userdata for sub-type of uv_handle_t

Gets the platform dependent file descriptor equivalent.

The following handles are supported: TCP, pipes, TTY, UDP and poll. Passing any other handle type will fail with EINVAL.

If a handle doesn't have an attached file descriptor yet or the handle itself has been closed, this function will return EBADF.

Returns: integer or fail

WARNING: Be very careful when using this function. libuv assumes it's in control of the file descriptor so any change to it may lead to malfunction.

uv.handle_get_type({handle}) uv.handle_get_type()

> method form handle:get_type()

Parameters:

- handle: userdata for sub-type of uv_handle_t

Returns the name of the struct for a given handle (e.g. "pipe" for uv_pipe_t) and the libuv enum integer for the handle's type (uv_handle_type).

Returns: string, integer

REFERENCE COUNTING luv-reference-counting

The libuv event loop (if run in the default mode) will run until there are no active and referenced handles left. The user can force the loop to exit early by unreferencing handles which are active, for example by calling uv.unref() after calling uv.timer_start().

A handle can be referenced or unreferenced, the refcounting scheme doesn't use a counter, so both operations are idempotent.

All handles are referenced when active by default, see uv.is_active() for a more detailed explanation on what being active involves.

uv_timer_t — Timer handle

luv-timer-handle uv_timer_t

> uv_handle_t functions also apply.

Timer handles are used to schedule callbacks to be called in the future.

uv.new_timer() uv.new_timer()

Creates and initializes a new uv_timer_t. Returns the Lua userdata wrapping it.

Returns: uv_timer_t userdata or fail

```
-- Creating a simple setTimeout wrapper
local function setTimeout(timeout, callback)
  local timer = uv.new_timer()
  timer:start(timeout, 0, function ()
    timer:stop()
    timer:close()
    callback()
  end)
  return timer
end

-- Creating a simple setInterval wrapper
local function setInterval(interval, callback)
  local timer = uv.new_timer()
  timer:start(interval, interval, function ()
    callback()
  end)
  return timer
end

-- And clearInterval
local function clearInterval(timer)
  timer:stop()
  timer:close()
end
```

uv.timer_start({timer}, {timeout}, {repeat}, {callback}) uv.timer_start()

> method form timer:start(timeout, repeat, callback)

Parameters:

- timer: uv_timer_t userdata
- timeout: integer
- repeat: integer
- callback: callable

Start the timer. timeout and repeat are in milliseconds.

If timeout is zero, the callback fires on the next event loop iteration. If repeat is non-zero, the callback fires first after timeout milliseconds and then repeatedly after repeat milliseconds.

Returns: 0 or fail

uv.timer_stop({timer}) uv.timer_stop()

> method form timer:stop()

Parameters:

- timer: uv_timer_t userdata

Stop the timer, the callback will not be called anymore.

Returns: 0 or fail

uv.timer_again({timer}) uv.timer_again()

> method form timer:again()

Parameters:

- timer: uv_timer_t userdata

Stop the timer, and if it is repeating restart it using the repeat value as the timeout. If the timer has never been started before it raises EINVAL.

Returns: 0 or fail

uv.timer_set_repeat({timer}, {repeat}) uv.timer_set_repeat()

> method form timer:set_repeat(repeat)

Parameters:

- timer: uv_timer_t userdata

- repeat: integer

Set the repeat interval value in milliseconds. The timer will be scheduled to run on the given interval, regardless of the callback execution duration, and will follow normal timer semantics in the case of a time-slice overrun.

For example, if a 50 ms repeating timer first runs for 17 ms, it will be scheduled to run again 33 ms later. If other tasks consume more than the 33 ms following the first timer callback, then the callback will run as soon as possible.

Returns: Nothing.

uv.timer_get_repeat({timer}) uv.timer_get_repeat()

> method form timer:get_repeat()

Parameters:
- timer: uv_timer_t userdata

Get the timer repeat value.

Returns: integer

uv.timer_get_due_in({timer}) uv.timer_get_due_in()

> method form timer:get_due_in()

Parameters:
- timer: uv_timer_t userdata

Get the timer due value or 0 if it has expired. The time is relative to uv.now().

Returns: integer

Note: New in libuv version 1.40.0.

uv_prepare_t — Prepare handle luv-prepare-handle uv_prepare_t

> uv_handle_t functions also apply.

Prepare handles will run the given callback once per loop iteration, right before polling for I/O.

```
local prepare = uv.new_prepare()
prepare:start(function()
  print("Before I/O polling")
end)
```

uv.new_prepare() uv.new_prepare()

Creates and initializes a new uv_prepare_t. Returns the Lua userdata wrapping it.

Returns: uv_prepare_t userdata

uv.prepare_start({prepare}, {callback}) uv.prepare_start()

> method form prepare:start(callback)

Parameters:
- prepare: uv_prepare_t userdata

- callback: callable

Start the handle with the given callback.

Returns: 0 or fail

uv.prepare_stop({prepare}) uv.prepare_stop()

> method form prepare:stop()

Parameters:
- prepare: uv_prepare_t userdata

Stop the handle, the callback will no longer be called.

Returns: 0 or fail

uv_check_t — Check handle luv-check-handle uv_check_t

> uv_handle_t functions also apply.

Check handles will run the given callback once per loop iteration, right after polling for I/O.

```
local check = uv.new_check()
check:start(function()
  print("After I/O polling")
end)
```

uv.new_check() uv.new_check()

Creates and initializes a new uv_check_t. Returns the Lua userdata wrapping it.

Returns: uv_check_t userdata

uv.check_start({check}, {callback}) uv.check_start()

> method form check:start(callback)

Parameters:

- check: uv_check_t userdata
- callback: callable

Start the handle with the given callback.

Returns: 0 or fail

uv.check_stop({check}) uv.check_stop()

> method form check:stop()

Parameters:

- check: uv_check_t userdata

Stop the handle, the callback will no longer be called.

Returns: 0 or fail

uv_idle_t — Idle handle luv-idle-handle uv_idle_t

> uv_handle_t functions also apply.

Idle handles will run the given callback once per loop iteration, right before the uv_prepare_t handles.

Note: The notable difference with prepare handles is that when there are active idle handles, the loop will perform a zero timeout poll instead of blocking for I/O.

WARNING: Despite the name, idle handles will get their callbacks called on every loop iteration, not when the loop is actually "idle".

```
local idle = uv.new_idle()
idle:start(function()
  print("Before I/O polling, no blocking")
end)
```

uv.new_idle() uv.new_idle()

Creates and initializes a new uv_idle_t. Returns the Lua userdata wrapping it.

Returns: uv_idle_t userdata

uv.idle_start({idle}, {callback}) uv.idle_start()

> method form idle:start(callback)

Parameters:

- idle: uv_idle_t userdata
- callback: callable

Start the handle with the given callback.

Returns: 0 or fail

uv.idle_stop({check}) uv.idle_stop()

> method form idle:stop()

Parameters:

- idle: uv_idle_t userdata

Stop the handle, the callback will no longer be called.

Returns: 0 or fail

uv_async_t — Async handle luv-async-handle uv_async_t

> uv_handle_t functions also apply.

Async handles allow the user to "wakeup" the event loop and get a callback called from another thread.

```
local async
async = uv.new_async(function()
  print("async operation ran")
  async:close()
end)

async:send()
```

uv.new_async({callback}) uv.new_async()

Parameters:

- callback: callable
- ...: threadargs passed to/from uv.async_send(async, ...)

Creates and initializes a new uv_async_t. Returns the Lua userdata wrapping it.

Returns: uv_async_t userdata or fail

Note: Unlike other handle initialization functions, this immediately starts the handle.

uv.async_send({async}, {...}) uv.async_send()

> method form async:send(...)

Parameters:

- async: uv_async_t userdata
- ...: threadargs

Wakeup the event loop and call the async handle's callback.

Returns: 0 or fail

Note: It's safe to call this function from any thread. The callback will be called on the loop thread.

WARNING: libuv will coalesce calls to uv.async_send(async), that is, not every call to it will yield an execution of the callback. For example: if uv.async_send() is called 5 times in a row before the callback is called, the callback will only be called once. If uv.async_send() is called again after the callback was called, it will be called again.

uv_poll_t — Poll handle luv-poll-handle uv_poll_t

> uv_handle_t functions also apply.

Poll handles are used to watch file descriptors for readability and writability, similar to the purpose of poll(2) (https://linux.die.net/man/2/poll).

The purpose of poll handles is to enable integrating external libraries that rely on the event loop to signal it about the socket status changes, like c-ares or libssh2. Using uv_poll_t for any other purpose is not recommended; uv_tcp_t, uv_udp_t, etc. provide an implementation that is faster and more scalable than what can be achieved with uv_poll_t, especially on Windows.

It is possible that poll handles occasionally signal that a file descriptor is readable or writable even when it isn't. The user should therefore always be prepared to handle EAGAIN or equivalent when it attempts to read from or write to the fd.

It is not okay to have multiple active poll handles for the same socket, this can cause libuv to busyloop or otherwise malfunction.

The user should not close a file descriptor while it is being polled by an active poll handle. This can cause the handle to report an error, but it might also start polling another socket. However the fd can be safely closed immediately after a call to uv.poll_stop() or uv.close().

Note: On windows only sockets can be polled with poll handles. On Unix any file descriptor that would be accepted by poll(2) can be used.

uv.new_poll({fd}) uv.new_poll()

Parameters:

- fd: integer

Initialize the handle using a file descriptor.

The file descriptor is set to non-blocking mode.

Returns: uv_poll_t userdata or fail

uv.new_socket_poll({fd}) uv.new_socket_poll()

Parameters:

- fd: integer

Initialize the handle using a socket descriptor. On Unix this is identical to uv.new_poll(). On windows it takes a SOCKET handle.

The socket is set to non-blocking mode.

Returns: uv_poll_t userdata or fail

uv.poll_start({poll}, {events}, {callback}) uv.poll_start()

> method form poll:start(events, callback)

Parameters:

- poll: uv_poll_t userdata
- events: string or nil (default: "rw")
- callback: callable
  - err: nil or string
  - events: string or nil

Starts polling the file descriptor. events are: "r", "w", "rw", "d", "rd", "wd", "rwd", "p", "rp", "wp", "rwp", "dp", "rdp", "wdp", or "rwdp" where r is READABLE, w is WRITABLE, d is DISCONNECT, and p is PRIORITIZED. As soon as an event is detected the callback will be called with status set to 0, and the detected events set on the events field.

The user should not close the socket while the handle is active. If the user does that anyway, the callback may be called reporting an error status, but this is not guaranteed.

Returns: 0 or fail

Note Calling uv.poll_start() on a handle that is already active is fine. Doing so will update the events mask that is being watched for.

uv.poll_stop({poll}) uv.poll_stop()

> method form poll:stop()

Parameters:

- poll: uv_poll_t userdata

Stop polling the file descriptor, the callback will no longer be called.

Returns: 0 or fail

uv_signal_t — Signal handle luv-signal-handle uv_signal_t

> uv_handle_t functions also apply.

Signal handles implement Unix style signal handling on a per-event loop bases.

Windows **Notes:**

Reception of some signals is emulated on Windows:

- SIGINT is normally delivered when the user presses CTRL+C. However, like on Unix, it is not generated when terminal raw mode is enabled.
- SIGBREAK is delivered when the user pressed CTRL + BREAK.
- SIGHUP is generated when the user closes the console window. On SIGHUP the program is given approximately 10 seconds to perform cleanup. After that Windows will unconditionally terminate it.
- SIGWINCH is raised whenever libuv detects that the console has been resized. SIGWINCH is emulated by libuv when the program uses a uv_tty_t handle to write to the console. SIGWINCH may not always be delivered in a timely manner; libuv will only detect size changes when the cursor is being moved. When a readable uv_tty_t handle is used in raw mode, resizing the console buffer will also trigger a SIGWINCH signal.
- Watchers for other signals can be successfully created, but these signals are never received. These signals are: SIGILL, SIGABRT, SIGFPE, SIGSEGV, SIGTERM and SIGKILL.
- Calls to raise() or abort() to programmatically raise a signal are not detected by libuv; these will not trigger a signal watcher.

Unix **Notes:**

- SIGKILL and SIGSTOP are impossible to catch.
- Handling SIGBUS, SIGFPE, SIGILL or SIGSEGV via libuv results into undefined behavior.
- SIGABRT will not be caught by libuv if generated by abort(), e.g. through assert().
- On Linux SIGRT0 and SIGRT1 (signals 32 and 33) are used by the NPTL pthreads library to manage threads. Installing watchers for those signals will lead to unpredictable behavior and is strongly discouraged. Future versions of libuv may simply reject them.

```
-- Create a new signal handler
local signal = uv.new_signal()
-- Define a handler function
uv.signal_start(signal, "sigint", function(signame)
  print("got " .. signame .. ", shutting down")
  os.exit(1)
end)
```

uv.new_signal() uv.new_signal()

Creates and initializes a new uv_signal_t. Returns the Lua userdata wrapping it.

Returns: uv_signal_t userdata or fail

uv.signal_start({signal}, {signame}, {callback}) uv.signal_start()

> method form signal:start(signame, callback)

Parameters:

- signal: uv_signal_t userdata
- signame: string or integer
- callback: callable
    - signame: string

Start the handle with the given callback, watching for the given signal.

See luv-constants for supported signame input and output values.

Returns: 0 or fail

uv.signal_start_oneshot() uv.signal_start_oneshot()

uv.signal_start_oneshot({signal}, {signame}, {callback})

> method form signal:start_oneshot(signame, callback)

Parameters:

- signal: uv_signal_t userdata
- signame: string or integer
- callback: callable
    - signame: string

Same functionality as uv.signal_start() but the signal handler is reset the moment the signal is received.

See luv-constants for supported signame input and output values.

Returns: 0 or fail

uv.signal_stop({signal}) uv.signal_stop()

> method form signal:stop()

Parameters:

- signal: uv_signal_t userdata

Stop the handle, the callback will no longer be called.

Returns: 0 or fail

uv_process_t — Process handle

luv-process-handle uv_process_t

> uv_handle_t functions also apply.

Process handles will spawn a new process and allow the user to control it and establish communication channels with it using streams.

uv.disable_stdio_inheritance()

uv.disable_stdio_inheritance()

Disables inheritance for file descriptors / handles that this process inherited from its parent. The effect is that child processes spawned by this process don't accidentally inherit these handles.

It is recommended to call this function as early in your program as possible, before the inherited file descriptors can be closed or duplicated.

Returns: Nothing.

Note: This function works on a best-effort basis: there is no guarantee that libuv can discover all file descriptors that were inherited. In general it does a better job on Windows than it does on Unix.

uv.spawn({path}, {options}, {on_exit})

uv.spawn()

Parameters:

- path: string
- options: table (see below)
- on_exit: callable
  - code: integer
  - signal: integer

Initializes the process handle and starts the process. If the process is successfully spawned, this function will return the handle and pid of the child process.

Possible reasons for failing to spawn would include (but not be limited to) the file to execute not existing, not having permissions to use the setuid or setgid specified, or not having enough memory to allocate for the new process.

```
local stdin = uv.new_pipe()
local stdout = uv.new_pipe()
local stderr = uv.new_pipe()

print("stdin", stdin)
print("stdout", stdout)
print("stderr", stderr)

local handle, pid = uv.spawn("cat", {
  stdio = {stdin, stdout, stderr}
}, function(code, signal) -- on exit
  print("exit code", code)
  print("exit signal", signal)
end)

print("process opened", handle, pid)

uv.read_start(stdout, function(err, data)
  assert(not err, err)
  if data then
    print("stdout chunk", stdout, data)
  else
    print("stdout end", stdout)
  end
end)

uv.read_start(stderr, function(err, data)
  assert(not err, err)
  if data then
    print("stderr chunk", stderr, data)
  else
    print("stderr end", stderr)
  end
end)

uv.write(stdin, "Hello World")

uv.shutdown(stdin, function()
  print("stdin shutdown", stdin)
  uv.close(handle, function()
    print("process closed", handle, pid)
  end)
end)
```

uv.spawn-options

The options table accepts the following fields:

- options.args - Command line arguments as a list of strings. The first string should not be the path to the program, since that is already provided via path. On Windows, this uses CreateProcess which concatenates the arguments into a string. This can cause some strange errors (see options.verbatim below for Windows).
- options.stdio - Set the file descriptors that will be made available to the child process. The convention is that the first entries are stdin, stdout, and stderr. (**Note:** On Windows, file descriptors after the third are available to the child process only if the child processes uses the MSVCRT runtime.)
- options.env - Set environment variables for the new process. Each entry should be a string in the form of NAME=VALUE.
- options.cwd - Set the current working directory for the sub-process.
- options.uid - Set the child process' user id.
- options.gid - Set the child process' group id.
- options.verbatim - If true, do not wrap any arguments in quotes, or perform any other escaping, when converting the argument list into a command line string. This option is only meaningful on Windows systems. On Unix it is silently ignored.
- options.detached - If true, spawn the child process in a detached state - this will make it a process group leader,

and will effectively enable the child to keep running
after the parent exits. Note that the child process will
still keep the parent's event loop alive unless the parent
process calls uv.unref() on the child's process handle.

- options.hide - If true, hide the subprocess console

window that would normally be created. This option is only
meaningful on Windows systems. On Unix it is silently
ignored.

The options.stdio entries can take many shapes.

- If they are numbers, then the child process inherits that

same zero-indexed fd from the parent process.

- If uv_stream_t handles are passed in, those are used as

a read-write pipe or inherited stream depending if the
stream has a valid fd.

- Including nil placeholders means to ignore that fd in

the child process.

When the child process exits, on_exit is called with an exit
code and signal.

Returns: uv_process_t userdata or nil, integer or
string, uv.error_name or nil

uv.process_kill({process}, {signame}) uv.process_kill()

> method form process:kill(signame)

Parameters:

- process: uv_process_t userdata

- signame: string or integer or nil (default: sigterm)

Sends the specified signal to the given process handle. Check
the documentation on uv_signal_t for signal support,
specially on Windows.

See luv-constants for supported signame input and output
values.

Returns: 0 or fail

uv.kill({pid}, {signame}) uv.kill()

Parameters:

- pid: integer

- signame: string or integer or nil (default: sigterm)

Sends the specified signal to the given PID. Check the
documentation on uv_signal_t for signal support, specially
on Windows.

See luv-constants for supported signame input and output
values.

Returns: 0 or fail

uv.process_get_pid({process}) uv.process_get_pid()

> method form process:get_pid()

Parameters:

- process: uv_process_t userdata

Returns the handle's pid.

Returns: integer

uv_stream_t — Stream handle luv-stream-handle uv_stream_t

> uv_handle_t functions also apply.

Stream handles provide an abstraction of a duplex communication channel.
uv_stream_t is an abstract type, libuv provides 3 stream implementations
in the form of uv_tcp_t, uv_pipe_t and uv_tty_t.

uv.shutdown({stream} [, {callback}]) uv.shutdown()

> method form stream:shutdown([callback])

Parameters:

- stream: userdata for sub-type of uv_stream_t

- callback: callable or nil
    - err: nil or string

Shutdown the outgoing (write) side of a duplex stream. It waits for pending write requests to complete. The callback is called after shutdown is complete.

Returns: uv_shutdown_t userdata or fail

uv.listen({stream}, {backlog}, {callback}) uv.listen()

> method form stream:listen(backlog, callback)

Parameters:

- stream: userdata for sub-type of uv_stream_t
- backlog: integer
- callback: callable
    - err: nil or string

Start listening for incoming connections. backlog indicates the number of connections the kernel might queue, same as listen(2). When a new incoming connection is received the callback is called.

Returns: 0 or fail

uv.accept({stream}, {client_stream}) uv.accept()

> method form stream:accept(client_stream)

Parameters:

- stream: userdata for sub-type of uv_stream_t
- client_stream: userdata for sub-type of uv_stream_t

This call is used in conjunction with uv.listen() to accept incoming connections. Call this function after receiving a callback to accept the connection.

When the connection callback is called it is guaranteed that this function will complete successfully the first time. If you attempt to use it more than once, it may fail. It is suggested to only call this function once per connection call.

Returns: 0 or fail

```
server:listen(128, function (err)
  local client = uv.new_tcp()
  server:accept(client)
end)
```

uv.read_start({stream}, {callback}) uv.read_start()

> method form stream:read_start(callback)

Parameters:

- stream: userdata for sub-type of uv_stream_t
- callback: callable
    - err: nil or string
    - data: string or nil

Read data from an incoming stream. The callback will be made several times until there is no more data to read or uv.read_stop() is called. When we've reached EOF, data will be nil.

Returns: 0 or fail

```
stream:read_start(function (err, chunk)
  if err then
    -- handle read error
  elseif chunk then
    -- handle data
  else
    -- handle disconnect
  end
end)
```

uv.read_stop({stream}) uv.read_stop()

> method form stream:read_stop()

Parameters:

- stream: userdata for sub-type of uv_stream_t

Stop reading data from the stream. The read callback will no longer be called.

This function is idempotent and may be safely called on a stopped stream.

Returns: 0 or fail

uv.write({stream}, {data} [, {callback}]) uv.write()

> method form stream:write(data, [callback])

Parameters:

- stream: userdata for sub-type of uv_stream_t
- data: buffer
- callback: callable or nil
    - err: nil or string

Write data to stream.

data can either be a Lua string or a table of strings. If a table is passed in, the C backend will use writev to send all strings in a single system call.

The optional callback is for knowing when the write is complete.

Returns: uv_write_t userdata or fail

uv.write2({stream}, {data}, {send_handle} [, {callback}]) uv.write2()

> method form stream:write2(data, send_handle, [callback])

Parameters:

- stream: userdata for sub-type of uv_stream_t
- data: buffer
- send_handle: userdata for sub-type of uv_stream_t
- callback: callable or nil
    - err: nil or string

Extended write function for sending handles over a pipe. The pipe must be initialized with ipc option true.

Returns: uv_write_t userdata or fail

Note: send_handle must be a TCP socket or pipe, which is a server or a connection (listening or connected state). Bound sockets or pipes will be assumed to be servers.

uv.try_write({stream}, {data}) uv.try_write()

> method form stream:try_write(data)

Parameters:

- stream: userdata for sub-type of uv_stream_t
- data: buffer

Same as uv.write(), but won't queue a write request if it can't be completed immediately.

Will return number of bytes written (can be less than the supplied buffer size).

Returns: integer or fail

uv.try_write2({stream}, {data}, {send_handle}) uv.try_write2()

> method form stream:try_write2(data, send_handle)

Parameters:

- stream: userdata for sub-type of uv_stream_t
- data: buffer
- send_handle: userdata for sub-type of uv_stream_t

Like uv.write2(), but with the properties of uv.try_write(). Not supported on Windows, where it returns UV_EAGAIN.

Will return number of bytes written (can be less than the supplied buffer size).

Returns: integer or fail

uv.is_readable({stream}) uv.is_readable()

> method form stream:is_readable()

Parameters:

- stream: userdata for sub-type of uv_stream_t

Returns true if the stream is readable, false otherwise.

Returns: boolean

uv.is_writable({stream}) uv.is_writable()

> method form stream:is_writable()

Parameters:

- stream: userdata for sub-type of uv_stream_t

Returns true if the stream is writable, false otherwise.

Returns: boolean

uv.stream_set_blocking({stream}, {blocking}) uv.stream_set_blocking()

> method form stream:set_blocking(blocking)

Parameters:

- stream: userdata for sub-type of uv_stream_t
- blocking: boolean

Enable or disable blocking mode for a stream.

When blocking mode is enabled all writes complete synchronously. The interface remains unchanged otherwise, e.g. completion or failure of the operation will still be reported through a callback which is made asynchronously.

Returns: 0 or fail

WARNING: Relying too much on this API is not recommended. It is likely to change significantly in the future. Currently this only works on Windows and only for uv_pipe_t handles. Also libuv currently makes no ordering guarantee when the blocking mode is changed after write requests have already been submitted. Therefore it is recommended to set the blocking mode immediately after opening or creating the stream.

uv.stream_get_write_queue_size() uv.stream_get_write_queue_size()

> method form stream:get_write_queue_size()

Returns the stream's write queue size.

Returns: integer

uv_tcp_t – TCP handle luv-tcp-handle uv_tcp_t

> uv_handle_t and uv_stream_t functions also apply.

TCP handles are used to represent both TCP streams and servers.

uv.new_tcp([{flags}]) uv.new_tcp()

Parameters:

- flags: string or integer or nil

Creates and initializes a new uv_tcp_t. Returns the Lua userdata wrapping it.

If set, flags must be a valid address family. See luv-constants for supported address family input values.

Returns: uv_tcp_t userdata or fail

uv.tcp_open({tcp}, {sock}) uv.tcp_open()

> method form tcp:open(sock)

Parameters:

- tcp: uv_tcp_t userdata
- sock: integer

Open an existing file descriptor or SOCKET as a TCP handle.

Returns: 0 or fail

Note: The passed file descriptor or SOCKET is not checked for its type, but it's required that it represents a valid stream socket.

uv.tcp_nodelay({tcp}, {enable}) uv.tcp_nodelay()

> method form tcp:nodelay(enable)

Parameters:

- tcp: uv_tcp_t userdata
- enable: boolean

Enable / disable Nagle's algorithm.

Returns: 0 or fail

uv.tcp_keepalive()

uv.tcp_keepalive({tcp}, {enable} [, {delay}, {intvl}, {cnt}])

> method form tcp:keepalive(enable, [delay], [intvl], [cnt])

Parameters:

- tcp: uv_tcp_t userdata
- enable: boolean
- delay: integer or nil
- intvl: integer or nil
- cnt: integer or nil

Enable / disable TCP keep-alive. delay is the initial delay in seconds, intvl is the time in seconds between individual keep-alive probes, and cnt is the number of probes to send before assuming the connection is dead.
Ignored when enable is false.

Returns: 0 or fail

Note: intvl and cnt are only supported with Libuv >= 1.52.0.

uv.tcp_simultaneous_accepts({tcp}, {enable}) uv.tcp_simultaneous_accepts()

> method form tcp:simultaneous_accepts(enable)

Parameters:

- tcp: uv_tcp_t userdata
- enable: boolean

Enable / disable simultaneous asynchronous accept requests that are queued by the operating system when listening for new TCP connections.

This setting is used to tune a TCP server for the desired performance. Having simultaneous accepts can significantly improve the rate of accepting connections (which is why it is enabled by default) but may lead to uneven load distribution in multi-process setups.

Returns: 0 or fail

uv.tcp_bind({tcp}, {host}, {port} [, {flags}]) uv.tcp_bind()

> method form tcp:bind(host, port, [flags])

Parameters:

- tcp: uv_tcp_t userdata
- host: string

- port: integer
- flags: table or nil
    - ipv6only: boolean

Bind the handle to an host and port. host should be an IP address and not a domain name. Any flags are set with a table with field ipv6only equal to true or false.

When the port is already taken, you can expect to see an EADDRINUSE error from either uv.tcp_bind(), uv.listen() or uv.tcp_connect(). That is, a successful call to this function does not guarantee that the call to uv.listen() or uv.tcp_connect() will succeed as well.

Use a port of 0 to let the OS assign an ephemeral port. You can look it up later using uv.tcp_getsockname().

Returns: 0 or fail

uv.tcp_getpeername({tcp}) uv.tcp_getpeername()

> method form tcp:getpeername()

Parameters:
- tcp: uv_tcp_t userdata

Get the address of the peer connected to the handle.

See luv-constants for supported address family output values.

Returns: table or fail
- ip : string
- family : string
- port : integer

uv.tcp_getsockname({tcp}) uv.tcp_getsockname()

> method form tcp:getsockname()

Parameters:
- tcp: uv_tcp_t userdata

Get the current address to which the handle is bound.

See luv-constants for supported address family output values.

Returns: table or fail
- ip : string
- family : string
- port : integer

uv.tcp_connect({tcp}, {host}, {port}, {callback}) uv.tcp_connect()

> method form tcp:connect(host, port, callback)

Parameters:
- tcp: uv_tcp_t userdata
- host: string
- port: integer
- callback: callable
    - err: nil or string

Establish an IPv4 or IPv6 TCP connection.

Returns: uv_connect_t userdata or fail

```
local client = uv.new_tcp()
client:connect("127.0.0.1", 8080, function (err)
  -- check error and carry on.
end)
```

uv.tcp_write_queue_size({tcp}) uv.tcp_write_queue_size()

> method form tcp:write_queue_size()

DEPRECATED: Please use uv.stream_get_write_queue_size() instead.

uv.tcp_close_reset([{callback}]) uv.tcp_close_reset()

> method form tcp:close_reset([callback])

Parameters:

- tcp: uv_tcp_t userdata
- callback: callable or nil

Resets a TCP connection by sending a RST packet. This is accomplished by setting the SO_LINGER socket option with a linger interval of zero and then calling uv.close(). Due to some platform inconsistencies, mixing of uv.shutdown() and uv.tcp_close_reset() calls is not allowed.

Returns: 0 or fail

uv.socketpair()

uv.socketpair([{socktype}, [{protocol}, [{flags1}, [{flags2}]]]])

Parameters:

- socktype: string, integer or nil (default: stream)
- protocol: string, integer or nil (default: 0)
- flags1: table or nil
  - nonblock: boolean (default: false)
- flags2: table or nil
  - nonblock: boolean (default: false)

Create a pair of connected sockets with the specified properties. The resulting handles can be passed to uv.tcp_open(), used with uv.spawn(), or for any other purpose.

See luv-constants for supported socktype input values.

When protocol is set to 0 or nil, it will be automatically chosen based on the socket's domain and type. When protocol is specified as a string, it will be looked up using the getprotobyname(3) function (examples: "ip", "icmp", "tcp", "udp", etc).

Flags:

- nonblock: Opens the specified socket handle for OVERLAPPED or FIONBIO/`O_NONBLOCK` I/O usage. This is recommended for handles that will be used by libuv, and not usually recommended otherwise.

Equivalent to socketpair(2) with a domain of AF_UNIX.

Returns: table or fail

- [1, 2] : integer (file descriptor)

```
-- Simple read/write with tcp
local fds = uv.socketpair(nil, nil, {nonblock=true}, {nonblock=true})

local sock1 = uv.new_tcp()
sock1:open(fds[1])

local sock2 = uv.new_tcp()
sock2:open(fds[2])

sock1:write("hello")
sock2:read_start(function(err, chunk)
  assert(not err, err)
  print(chunk)
end)
```

uv_pipe_t — Pipe handle

luv-pipe-handle uv_pipe_t

> uv_handle_t and uv_stream_t functions also apply.

Pipe handles provide an abstraction over local domain sockets on Unix and named pipes on Windows.

```
local pipe = uv.new_pipe(false)

pipe:bind('/tmp/sock.test')

pipe:listen(128, function()
  local client = uv.new_pipe(false)
  pipe:accept(client)
  client:write("hello!\n")
  client:close()
end)
```

uv.new_pipe([{ipc}]) uv.new_pipe()

Parameters:

- ipc: boolean or nil (default: false)

Creates and initializes a new uv_pipe_t. Returns the Lua userdata wrapping it. The ipc argument is a boolean to indicate if this pipe will be used for handle passing between processes.

Returns: uv_pipe_t userdata or fail

uv.pipe_open({pipe}, {fd}) uv.pipe_open()

> method form pipe:open(fd)

Parameters:

- pipe: uv_pipe_t userdata
- fd: integer

Open an existing file descriptor or uv_handle_t as a pipe.

Returns: 0 or fail

Note: The file descriptor is set to non-blocking mode.

uv.pipe_bind({pipe}, {name}) uv.pipe_bind()

> method form pipe:bind(name)

Parameters:

- pipe: uv_pipe_t userdata
- name: string

Bind the pipe to a file path (Unix) or a name (Windows).

Returns: 0 or fail

Note: Paths on Unix get truncated to sizeof(sockaddr_un.sun_path) bytes, typically between 92 and 108 bytes.

uv.pipe_connect({pipe}, {name} [, {callback}]) uv.pipe_connect()

> method form pipe:connect(name, [callback])

Parameters:

- pipe: uv_pipe_t userdata
- name: string
- callback: callable or nil
    - err: nil or string

Connect to the Unix domain socket or the named pipe.

Returns: uv_connect_t userdata or fail

Note: Paths on Unix get truncated to sizeof(sockaddr_un.sun_path) bytes, typically between 92 and 108 bytes.

uv.pipe_getsockname({pipe}) uv.pipe_getsockname()

> method form pipe:getsockname()

Parameters:

- pipe: uv_pipe_t userdata

Get the name of the Unix domain socket or the named pipe.

Returns: string or fail

uv.pipe_getpeername({pipe}) uv.pipe_getpeername()

> method form pipe:getpeername()

Parameters:

- pipe: uv_pipe_t userdata

Get the name of the Unix domain socket or the named pipe to which the handle is connected.

Returns: string or fail

uv.pipe_pending_instances({pipe}, {count}) uv.pipe_pending_instances()

> method form pipe:pending_instances(count)

Parameters:

- pipe: uv_pipe_t userdata
- count: integer

Set the number of pending pipe instance handles when the pipe server is waiting for connections.

Returns: Nothing.

Note: This setting applies to Windows only.

uv.pipe_pending_count({pipe}) uv.pipe_pending_count()

> method form pipe:pending_count()

Parameters:

- pipe: uv_pipe_t userdata

Returns the pending pipe count for the named pipe.

Returns: integer

uv.pipe_pending_type({pipe}) uv.pipe_pending_type()

> method form pipe:pending_type()

Parameters:

- pipe: uv_pipe_t userdata

Used to receive handles over IPC pipes.

First - call uv.pipe_pending_count(), if it's > 0 then initialize a handle of the given type, returned by uv.pipe_pending_type() and call uv.accept(pipe, handle) .

Returns: string

uv.pipe_chmod({pipe}, {flags}) uv.pipe_chmod()

> method form pipe:chmod(flags)

Parameters:

- pipe: uv_pipe_t userdata
- flags: string

Alters pipe permissions, allowing it to be accessed from processes run by different users. Makes the pipe writable or readable by all users. flags are: "r", "w", "rw", or "wr" where r is READABLE and w is WRITABLE. This function is blocking.

Returns: 0 or fail

uv.pipe({read_flags}, {write_flags}) uv.pipe()

Parameters:

- read_flags: table or nil
  - nonblock: boolean (default: false)
- write_flags: table or nil
  - nonblock: boolean (default: false)

Create a pair of connected pipe handles. Data may be written to the write fd and read from the read fd. The resulting

handles can be passed to pipe_open, used with spawn, or
for any other purpose.

Flags:

- nonblock: Opens the specified socket handle for

  OVERLAPPED or FIONBIO/`O_NONBLOCK` I/O usage. This is
  recommended for handles that will be used by libuv, and not
  usually recommended otherwise.

Equivalent to pipe(2) with the O_CLOEXEC flag set.

Returns: table or fail

- read : integer (file descriptor)

- write : integer (file descriptor)

```
-- Simple read/write with pipe_open
local fds = uv.pipe({nonblock=true}, {nonblock=true})

local read_pipe = uv.new_pipe()
read_pipe:open(fds.read)

local write_pipe = uv.new_pipe()
write_pipe:open(fds.write)

write_pipe:write("hello")
read_pipe:read_start(function(err, chunk)
  assert(not err, err)
  print(chunk)
end)
```

uv.pipe_bind2({pipe}, {name}, {flags}) uv.pipe_bind2()

> method form pipe:pipe_bind(name, flags)

Parameters:

- pipe: uv_pipe_t userdata

- name: string

- flags: integer or table or nil (default: 0)

Flags:

- If type(flags) is number, it must be 0 or

  uv.constants.PIPE_NO_TRUNCATE.
- If type(flags) is table, it must be {} or

  { no_truncate = true|false }.
- If type(flags) is nil, it use default value 0.

- Returns EINVAL for unsupported flags without performing the

  bind.

Bind the pipe to a file path (Unix) or a name (Windows).

Supports Linux abstract namespace sockets. namelen must include
the leading '\0' byte but not the trailing nul byte.

Returns: 0 or fail

Note:

1. Paths on Unix get truncated to sizeof(sockaddr_un.sun_path)

   bytes, typically between 92 and 108 bytes.
2. New in version 1.46.0.

uv.pipe_connect2(pipe, name, [flags], [callback]) uv.pipe_connect2()

> method form pipe:connect2(name, [flags], [callback])

Parameters:

- pipe: uv_pipe_t userdata

- name: string

- flags: integer or table or nil (default: 0)

- callback: callable or nil
    - err: nil or string

Flags:

- If type(flags) is number, it must be 0 or uv.constants.PIPE_NO_TRUNCATE.
- If type(flags) is table, it must be {} or { no_truncate = true|false }.
- If type(flags) is nil, it use default value 0.
- Returns EINVAL for unsupported flags without performing the bind operation.

Connect to the Unix domain socket or the named pipe.

Supports Linux abstract namespace sockets. namelen must include the leading nul byte but not the trailing nul byte.

Returns: uv_connect_t userdata or fail

Note:

1. Paths on Unix get truncated to sizeof(sockaddr_un.sun_path) bytes, typically between 92 and 108 bytes.
2. New in version 1.46.0.

uv_tty_t — TTY handle

luv-tty-handle uv_tty_t

> uv_handle_t and uv_stream_t functions also apply.

TTY handles represent a stream for the console.

```
-- Simple echo program
local stdin = uv.new_tty(0, true)
local stdout = uv.new_tty(1, false)

stdin:read_start(function (err, data)
  assert(not err, err)
  if data then
    stdout:write(data)
  else
    stdin:close()
    stdout:close()
  end
end)
```

uv.new_tty({fd}, {readable}) uv.new_tty()

Parameters:

- fd: integer
- readable: boolean

Initialize a new TTY stream with the given file descriptor. Usually the file descriptor will be:

- 0 - stdin
- 1 - stdout
- 2 - stderr

On Unix this function will determine the path of the fd of the terminal using ttyname_r(3), open it, and use it if the passed file descriptor refers to a TTY. This lets libuv put the tty in non-blocking mode without affecting other processes that share the tty.

This function is not thread safe on systems that don’t support ioctl TIOCGPTN or TIOCPTYGNAME, for instance OpenBSD and Solaris.

Returns: uv_tty_t userdata or fail

Note: If reopening the TTY fails, libuv falls back to blocking writes.

uv.tty_set_mode({tty}, {mode}) uv.tty_set_mode()

> method form tty:set_mode(mode)

Parameters:

- tty: uv_tty_t userdata
- mode: string or integer

Set the TTY using the specified terminal mode.

See luv-constants for supported TTY mode input values.

Returns: 0 or fail

uv.tty_reset_mode() uv.tty_reset_mode()

To be called when the program exits. Resets TTY settings to default values for the next process to take over.

This function is async signal-safe on Unix platforms but can fail with error code EBUSY if you call it when execution is inside uv.tty_set_mode().

Returns: 0 or fail

uv.tty_get_winsize({tty}) uv.tty_get_winsize()

> method form tty:get_winsize()

Parameters:

- tty: uv_tty_t userdata

Gets the current Window width and height.

Returns: integer, integer or fail

uv.tty_set_vterm_state({state}) uv.tty_set_vterm_state()

Parameters:

- state: string

Controls whether console virtual terminal sequences are processed by libuv or console. Useful in particular for enabling ConEmu support of ANSI X3.64 and Xterm 256 colors. Otherwise Windows10 consoles are usually detected automatically. State should be one of: "supported" or "unsupported".

This function is only meaningful on Windows systems. On Unix it is silently ignored.

Returns: none

uv.tty_get_vterm_state() uv.tty_get_vterm_state()

Get the current state of whether console virtual terminal sequences are handled by libuv or the console. The return value is "supported" or "unsupported".

This function is not implemented on Unix, where it returns ENOTSUP.

Returns: string or fail

uv_udp_t — UDP handle luv-udp-handle uv_udp_t

> uv_handle_t functions also apply.

UDP handles encapsulate UDP communication for both clients and servers.

uv.new_udp([{flags}]) uv.new_udp()

Parameters:

- flags: table or nil
  - family: string or nil
  - mmsgs: integer or nil (default: 1)

Creates and initializes a new uv_udp_t. Returns the Lua userdata wrapping it. The actual socket is created lazily.

See luv-constants for supported address family input values.

When specified, mmsgs determines the number of messages able to be received at one time via recvmmsg(2) (the allocated buffer will be sized to be able to fit the specified number of max size dgrams). Only has an effect on platforms that support recvmmsg(2).

Note: For backwards compatibility reasons, flags can also be a string or integer. When it is a string, it will be treated

like the family key above. When it is an integer, it will be used directly as the flags parameter when calling uv_udp_init_ex.

Returns: uv_udp_t userdata or fail

uv.udp_get_send_queue_size() uv.udp_get_send_queue_size()

> method form udp:get_send_queue_size()

Returns the handle's send queue size.

Returns: integer

uv.udp_get_send_queue_count() uv.udp_get_send_queue_count()

> method form udp:get_send_queue_count()

Returns the handle's send queue count.

Returns: integer

uv.udp_open({udp}, {fd}, [{flags}]) uv.udp_open()

> method form udp:open(fd, [flags])

Parameters:

- udp: uv_udp_t userdata
- fd: integer
- flags: table or integer or nil
  - reuseaddr: boolean or nil
  - reuseport: boolean or nil

Opens an existing file descriptor or Windows SOCKET as a UDP handle.

Unix only: The only requirement of the sock argument is that it follows the datagram contract (works in unconnected mode, supports sendmsg()/recvmsg(), etc). In other words, other datagram-type sockets like raw sockets or netlink sockets can also be passed to this function.

The file descriptor is set to non-blocking mode.

Note: The passed file descriptor or SOCKET is not checked for its type, but it's required that it represents a valid datagram socket.

Returns: 0 or fail

Note: flags is only supported with Libuv >= 1.52.0.

uv.udp_bind({udp}, {host}, {port} [, {flags}]) uv.udp_bind()

> method form udp:bind(host, port, [flags])

Parameters:

- udp: uv_udp_t userdata
- host: string
- port: number
- flags: table or nil
  - ipv6only: boolean or nil
  - reuseaddr: boolean or nil
  - linux_recverr: boolean or nil
  - reuseport: boolean or nil

Bind the UDP handle to an IP address and port. Any flags are set with a table with fields reuseaddr, ipv6only, linux_recverr, reuseport equal to true or false.

- reuseaddr: Indicates if SO_REUSEADDR will be set when

  binding the handle. This sets the SO_REUSEPORT socket flag on the BSDs (except for DragonFlyBSD), OS X, and other platforms where SO_REUSEPORTs don't have the capability of load balancing, as the opposite of what reuseport would do. On

other Unix platforms, it sets the SO_REUSEADDR flag. What that means is that multiple threads or processes can bind to the same address without error (provided they all set the flag) but only the last one to bind will receive any traffic, in effect "stealing" the port from the previous listener.

- ipv6only: Disables dual stack mode.

- linux_recverr: Indicates if IP_RECVERR/IPV6_RECVERR will

be set when binding the handle. This sets IP_RECVERR for IPv4 and IPV6_RECVERR for IPv6 UDP sockets on Linux. This stops the Linux kernel from suppressing some ICMP error messages and enables full ICMP error reporting for faster failover. This flag is no-op on platforms other than Linux.

- reuseport: Indicates if SO_REUSEPORT will be set when

binding the handle. This sets the SO_REUSEPORT socket option on supported platforms. Unlike reuseaddr, this flag will make multiple threads or processes that are binding to the same address and port "share" the port, which means incoming datagrams are distributed across the receiving sockets among threads or processes. This flag is available only on Linux 3.9+, DragonFlyBSD 3.6+, FreeBSD 12.0+, Solaris 11.4, and AIX 7.2.5+ for now.

Returns: 0 or fail

Note: The flag linux_recverr is only supported with Libuv >= 1.42.0. The flag reuseport is only supported with Libuv >= 1.49.0.

uv.udp_getsockname({udp}) uv.udp_getsockname()

> method form udp:getsockname()

Parameters:

- udp: uv_udp_t userdata

Get the local IP and port of the UDP handle.

Returns: table or fail

- ip : string

- family : string

- port : integer

uv.udp_getpeername({udp}) uv.udp_getpeername()

> method form udp:getpeername()

Parameters:

- udp: uv_udp_t userdata

Get the remote IP and port of the UDP handle on connected UDP handles.

Returns: table or fail

- ip : string

- family : string

- port : integer

uv.udp_set_membership()

uv.udp_set_membership({udp}, {multicast_addr}, {interface_addr}, {membership})

> method form
> udp:set_membership(multicast_addr, interface_addr, membership)

Parameters:

- udp: uv_udp_t userdata

- multicast_addr: string

- interface_addr: string or nil

- membership: string

Set membership for a multicast address. multicast_addr is
multicast address to set membership for. interface_addr is
interface address. membership can be the string "leave" or
"join".

Returns: 0 or fail

uv.udp_set_source_membership()

uv.udp_set_source_membership({udp}, {multicast_addr}, {interface_addr}, {source_addr}, {membership})

> method form
> udp:set_source_membership(multicast_addr, interface_addr, source_addr, membership)

Parameters:

- udp: uv_udp_t userdata
- multicast_addr: string
- interface_addr: string or nil
- source_addr: string
- membership: string

Set membership for a source-specific multicast group.
multicast_addr is multicast address to set membership for.
interface_addr is interface address. source_addr is source
address. membership can be the string "leave" or "join".

Returns: 0 or fail

uv.udp_set_multicast_loop({udp}, {on}) uv.udp_set_multicast_loop()

> method form udp:set_multicast_loop(on)

Parameters:

- udp: uv_udp_t userdata
- on: boolean

Set IP multicast loop flag. Makes multicast packets loop back
to local sockets.

Returns: 0 or fail

uv.udp_set_multicast_ttl({udp}, {ttl}) uv.udp_set_multicast_ttl()

> method form udp:set_multicast_ttl(ttl)

Parameters:

- udp: uv_udp_t userdata
- ttl: integer

Set the multicast ttl.

ttl is an integer 1 through 255.

Returns: 0 or fail

uv.udp_set_multicast_interface()

uv.udp_set_multicast_interface({udp}, {interface_addr})

> method form udp:set_multicast_interface(interface_addr)

Parameters:

- udp: uv_udp_t userdata
- interface_addr: string

Set the multicast interface to send or receive data on.

Returns: 0 or fail

uv.udp_set_broadcast({udp}, {on}) uv.udp_set_broadcast()

> method form udp:set_broadcast(on)

Parameters:

- udp: uv_udp_t userdata
- on: boolean

Set broadcast on or off.

Returns: 0 or fail

uv.udp_set_ttl({udp}, {ttl}) uv.udp_set_ttl()

> method form udp:set_ttl(ttl)

Parameters:

- udp: uv_udp_t userdata
- ttl: integer

Set the time to live.

ttl is an integer 1 through 255.

Returns: 0 or fail

uv.udp_send({udp}, {data}, {host}, {port}, {callback}) uv.udp_send()

> method form udp:send(data, host, port, callback)

Parameters:

- udp: uv_udp_t userdata
- data: buffer
- host: string
- port: integer
- callback: callable
  - err: nil or string

Send data over the UDP socket. If the socket has not previously been bound with uv.udp_bind() it will be bound to 0.0.0.0 (the "all interfaces" IPv4 address) and a random port number.

Returns: uv_udp_send_t userdata or fail

uv.udp_try_send({udp}, {data}, {host}, {port}) uv.udp_try_send()

> method form udp:try_send(data, host, port)

Parameters:

- udp: uv_udp_t userdata
- data: buffer
- host: string
- port: integer

Same as uv.udp_send(), but won't queue a send request if it can't be completed immediately.

Returns: integer or fail

uv.udp_try_send2({udp}, {messages}, {flags}) uv.udp_try_send2()

> method form udp:try_send2(messages, flags)

Parameters:

- udp: uv_udp_t userdata
- messages: table
  - [1, 2, 3, ..., n] : table
    - data : buffer
    - addr : table
      - ip : string
      - port : integer

- flags: nil (see below)
- port: integer

Like uv.udp_try_send(), but can send multiple datagrams.
Lightweight abstraction around sendmmsg(2), with a
sendmsg(2) fallback loop for platforms that do not support
the former. The udp handle must be fully initialized, either
from a uv.udp_bind call, another call that will bind
automatically (udp_send, udp_try_send, etc), or from
uv.udp_connect. messages should be an array-like table,
where addr must be specified if the udp has not been
connected via udp_connect. Otherwise, addr must be nil.

flags is reserved for future extension and must currently be
nil or 0 or {}.

Returns the number of messages sent successfully. An error will only be returned
if the first datagram failed to be sent.

Returns: integer or fail

```
-- If client:connect(...) was not called
local addr = { ip = "127.0.0.1", port = 1234 }
client:try_send2({
  { data = "Message 1", addr = addr },
  { data = "Message 2", addr = addr },
})
-- If client:connect(...) was called
client:try_send2({
  { data = "Message 1" },
  { data = "Message 2" },
})
```

uv.udp_recv_start({udp}, {callback}) uv.udp_recv_start()

> method form udp:recv_start(callback)

Parameters:
- udp: uv_udp_t userdata
- callback: callable
  - err: nil or string
  - data: string or nil
  - addr: table or nil
    - ip: string
    - port: integer
    - family: string
  - flags: table
    - partial: boolean or nil
    - mmsg_chunk: boolean or nil

Prepare for receiving data. If the socket has not previously
been bound with uv.udp_bind() it is bound to 0.0.0.0 (the
"all interfaces" IPv4 address) and a random port number.

See luv-constants for supported address family output values.

Returns: 0 or fail

uv.udp_recv_stop({udp}) uv.udp_recv_stop()

> method form udp:recv_stop()

Parameters:
- udp: uv_udp_t userdata

Stop listening for incoming datagrams.

Returns: 0 or fail

uv.udp_connect({udp}, {host}, {port}) uv.udp_connect()

> method form udp:connect(host, port)

Parameters:

- udp: uv_udp_t userdata
- host: string
- port: integer

Associate the UDP handle to a remote address and port, so every message sent by this handle is automatically sent to that destination. Calling this function with a NULL addr disconnects the handle. Trying to call uv.udp_connect() on an already connected handle will result in an EISCONN error. Trying to disconnect a handle that is not connected will return an ENOTCONN error.

Returns: 0 or fail

uv_fs_event_t – FS Event handle luv-fs-event-handle uv_fs_event_t

> uv_handle_t functions also apply.

FS Event handles allow the user to monitor a given path for changes, for example, if the file was renamed or there was a generic change in it. This handle uses the best backend for the job on each platform.

uv.new_fs_event() uv.new_fs_event()

Creates and initializes a new uv_fs_event_t. Returns the Lua userdata wrapping it.

Returns: uv_fs_event_t userdata or fail

uv.fs_event_start({fs_event}, {path}, {flags}, {callback}) uv.fs_event_start()

> method form fs_event:start(path, flags, callback)

Parameters:

- fs_event: uv_fs_event_t userdata
- path: string
- flags: table
  - watch_entry: boolean or nil (default: false)
  - stat: boolean or nil (default: false)
  - recursive: boolean or nil (default: false)
- callback: callable
  - err: nil or string
  - filename: string
  - events: table
    - change: boolean or nil
    - rename: boolean or nil

Start the handle with the given callback, which will watch the specified path for changes.

Returns: 0 or fail

uv.fs_event_stop() uv.fs_event_stop()

> method form fs_event:stop()

Stop the handle, the callback will no longer be called.

Returns: 0 or fail

uv.fs_event_getpath() uv.fs_event_getpath()

> method form fs_event:getpath()

Get the path being monitored by the handle.

Returns: string or fail

uv_fs_poll_t — FS Poll handle

luv-fs-poll-handle uv_fs_poll_t

> uv_handle_t functions also apply.

FS Poll handles allow the user to monitor a given path for changes. Unlike uv_fs_event_t, fs poll handles use stat to detect when a file has changed so they can work on file systems where fs event handles can't.

uv.new_fs_poll() uv.new_fs_poll()

Creates and initializes a new uv_fs_poll_t. Returns the Lua userdata wrapping it.

Returns: uv_fs_poll_t userdata or fail

uv.fs_poll_start({fs_poll}, {path}, {interval}, {callback}) uv.fs_poll_start()

> method form fs_poll:start(path, interval, callback)

Parameters:

- fs_poll: uv_fs_poll_t userdata
- path: string
- interval: integer
- callback: callable
  - err: nil or string
  - prev: table or nil (see uv.fs_stat)
  - curr: table or nil (see uv.fs_stat)

Check the file at path for changes every interval milliseconds.

Note: For maximum portability, use multi-second intervals. Sub-second intervals will not detect all changes on many file systems.

Returns: 0 or fail

uv.fs_poll_stop() uv.fs_poll_stop()

> method form fs_poll:stop()

Stop the handle, the callback will no longer be called.

Returns: 0 or fail

uv.fs_poll_getpath() uv.fs_poll_getpath()

> method form fs_poll:getpath()

Get the path being monitored by the handle.

Returns: string or fail

FILE SYSTEM OPERATIONS

luv-file-system-operations uv_fs_t

Most file system functions can operate synchronously or asynchronously. When a synchronous version is called (by omitting a callback), the function will immediately return the results of the FS call. When an asynchronous version is called (by providing a callback), the function will immediately return a uv_fs_t userdata and asynchronously execute its callback; if an error is encountered, the first and only argument passed to the callback will be the err error string; if the operation completes successfully, the first argument will be nil and the remaining arguments will be the results of the FS call.

Synchronous and asynchronous versions of readFile (with naive error handling) are implemented below as an example:

```
local function readFileSync(path)
  local fd = assert(uv.fs_open(path, "r", 438))
  local stat = assert(uv.fs_fstat(fd))
  local data = assert(uv.fs_read(fd, stat.size, 0))
  assert(uv.fs_close(fd))
  return data
end

local data = readFileSync("main.lua")
print("synchronous read", data)
```

```lua
local function readFile(path, callback)
  uv.fs_open(path, "r", 438, function(err, fd)
    assert(not err, err)
    uv.fs_fstat(fd, function(err, stat)
      assert(not err, err)
      uv.fs_read(fd, stat.size, 0, function(err, data)
        assert(not err, err)
        uv.fs_close(fd, function(err)
          assert(not err, err)
          return callback(data)
        end)
      end)
    end)
  end)
end

readFile("main.lua", function(data)
  print("asynchronous read", data)
end)
```

uv.fs_close({fd} [, {callback}]) uv.fs_close()

Parameters:

- fd: integer
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to close(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_open({path}, {flags}, {mode} [, {callback}]) uv.fs_open()

Parameters:

- path: string
- flags: string or integer
- mode: integer (octal chmod(1) mode, e.g. tonumber('644', 8))
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - fd: integer or nil

Equivalent to open(2). Access flags may be an integer or one of: "r", "rs", "sr", "r+", "rs+", "sr+", "w", "wx", "xw", "w+", "wx+", "xw+", "a", "ax", "xa", "a+", "ax+", or "`xa+`".

Returns (sync version): integer or fail

Returns (async version): uv_fs_t userdata

Note: On Windows, libuv uses CreateFileW and thus the file is always opened in binary mode. Because of this, the O_BINARY and O_TEXT flags are not supported.

uv.fs_read({fd}, {size} [, {offset} [, {callback}]]) uv.fs_read()

Parameters:

- fd: integer
- size: integer
- offset: integer or nil
- callback: callable (async version) or nil (sync version)

- err: nil or string
- data: string or nil

Equivalent to preadv(2). Returns any data. An empty string indicates EOF.

If offset is nil or omitted, it will default to -1, which indicates "use and update the current file offset."

Note: When offset is >= 0, the current file offset will not be updated by the read.

Returns (sync version): string or fail

Returns (async version): uv_fs_t userdata

uv.fs_unlink({path} [, {callback}]) uv.fs_unlink()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
- err: nil or string
- success: boolean or nil

Equivalent to unlink(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_write({fd}, {data} [, {offset} [, {callback}]]) uv.fs_write()

Parameters:

- fd: integer
- data: buffer
- offset: integer or nil
- callback: callable (async version) or nil (sync version)
- err: nil or string
- bytes: integer or nil

Equivalent to pwritev(2). Returns the number of bytes written.

If offset is nil or omitted, it will default to -1, which indicates "use and update the current file offset."

Note: When offset is >= 0, the current file offset will not be updated by the write.

Returns (sync version): integer or fail

Returns (async version): uv_fs_t userdata

uv.fs_mkdir({path}, {mode} [, {callback}]) uv.fs_mkdir()

Parameters:

- path: string
- mode: integer (octal representation of chmod(1) mode, e.g. tonumber('755', 8))
- callback: callable (async version) or nil (sync version)
- err: nil or string
- success: boolean or nil

Equivalent to mkdir(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_mkdtemp({template} [, {callback}]) uv.fs_mkdtemp()

Parameters:

- template: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - path: string or nil

Equivalent to mkdtemp(3).

Returns (sync version): string or fail

Returns (async version): uv_fs_t userdata

uv.fs_mkstemp({template} [, {callback}]) uv.fs_mkstemp()

Parameters:

- template: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - fd: integer or nil
  - path: string or nil

Equivalent to mkstemp(3). Returns a temporary file handle and filename.

Returns (sync version): integer, string or fail

Returns (async version): uv_fs_t userdata

uv.fs_rmdir({path} [, {callback}]) uv.fs_rmdir()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to rmdir(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_scandir({path} [, {callback}]) uv.fs_scandir()

Parameters:

- path: string
- callback: callable
  - err: nil or string
  - success: uv_fs_t userdata or nil

Equivalent to scandir(3), with a slightly different API. Returns a handle that the user can pass to uv.fs_scandir_next().

Note: This function can be used synchronously or asynchronously. The request userdata is always synchronously returned regardless of whether a callback is provided and the same userdata is passed to the callback if it is provided.

Returns: uv_fs_t userdata or fail

uv.fs_scandir_next({fs}) uv.fs_scandir_next()

Parameters:

- fs: uv_fs_t userdata

Called on a uv_fs_t returned by uv.fs_scandir() to get the next directory entry data as a name, type pair. When there are no more entries, nil is returned.

Note: This function only has a synchronous version. See uv.fs_opendir() and its related functions for an asynchronous version.

Returns: string, string or nil or fail

uv.fs_stat({path} [, {callback}]) uv.fs_stat()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - stat: table or nil (see below)

Equivalent to stat(2).

Returns (sync version): table or fail

- dev : integer
- mode : integer
- nlink : integer
- uid : integer
- gid : integer
- rdev : integer
- ino : integer
- size : integer
- blksize : integer
- blocks : integer
- flags : integer
- gen : integer
- atime : table
  - sec : integer
  - nsec : integer
- mtime : table
  - sec : integer
  - nsec : integer
- ctime : table

- sec : integer
- nsec : integer

- birthtime : table
  - sec : integer
  - nsec : integer

- type : string

Returns (async version): uv_fs_t userdata

uv.fs_fstat({fd} [, {callback}]) uv.fs_fstat()

Parameters:

- fd: integer
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - stat: table or nil (see uv.fs_stat)

Equivalent to fstat(2).

Returns (sync version): table or fail (see uv.fs_stat)

Returns (async version): uv_fs_t userdata

uv.fs_lstat({path} [, {callback}]) uv.fs_lstat()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - stat: table or nil (see uv.fs_stat)

Equivalent to lstat(2).

Returns (sync version): table or fail (see uv.fs_stat())

Returns (async version): uv_fs_t userdata

uv.fs_rename({path}, {new_path} [, {callback}]) uv.fs_rename()

Parameters:

- path: string
- new_path: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to rename(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_fsync({fd} [, {callback}]) uv.fs_fsync()

Parameters:

- fd: integer

- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - success: boolean or nil

  Equivalent to fsync(2).

  Returns (sync version): boolean or fail

  Returns (async version): uv_fs_t userdata

uv.fs_fdatasync({fd} [, {callback}]) uv.fs_fdatasync()

  Parameters:

- fd: integer
- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - success: boolean or nil

  Equivalent to fdatasync(2).

  Returns (sync version): boolean or fail

  Returns (async version): uv_fs_t userdata

uv.fs_ftruncate({fd}, {offset} [, {callback}]) uv.fs_ftruncate()

  Parameters:

- fd: integer
- offset: integer
- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - success: boolean or nil

  Equivalent to ftruncate(2).

  Returns (sync version): boolean or fail

  Returns (async version): uv_fs_t userdata

uv.fs_sendfile() uv.fs_sendfile()

uv.fs_sendfile({out_fd}, {in_fd}, {in_offset}, {size} [, {callback}])

  Parameters:

- out_fd: integer
- in_fd: integer
- in_offset: integer
- size: integer
- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - bytes: integer or nil

  Limited equivalent to sendfile(2). Returns the number of bytes written.

  Returns (sync version): integer or fail

  Returns (async version): uv_fs_t userdata

uv.fs_access({path}, {mode} [, {callback}]) uv.fs_access()

Parameters:

- path: string
- mode: integer string (a combination of the 'r', 'w' and 'x' characters denoting the symbolic mode as per chmod(1))
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - permission: boolean or nil

Equivalent to access(2) on Unix. Windows uses GetFileAttributesW(). Access mode can be an integer or a string containing "R" or "W" or "X". Returns true or false indicating access permission.

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_chmod({path}, {mode} [, {callback}]) uv.fs_chmod()

Parameters:

- path: string
- mode: integer (octal representation of chmod(1) mode, e.g. tonumber('644', 8))
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to chmod(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_fchmod({fd}, {mode} [, {callback}]) uv.fs_fchmod()

Parameters:

- fd: integer
- mode: integer
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to fchmod(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_utime({path} [, {atime}, {mtime}, {callback}]) uv.fs_utime()

Parameters:

- path: string
- atime: number or string or nil
- mtime: number or string or nil
- callback: callable (async version) or nil (sync

version)
- err: nil or string
- success: boolean or nil

Equivalent to utime(2).

See luv-constants for supported FS Modification Time constants.

Passing "now" or uv.constants.FS_UTIME_NOW as the atime or mtime sets the timestamp to the current time.

Passing nil, "omit", or uv.constants.FS_UTIME_OMIT as the atime or mtime leaves the timestamp untouched.

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_futime({fd} [, {atime}, {mtime}, {callback}]) uv.fs_futime()

Parameters:
- fd: integer
- atime: number or string or nil
- mtime: number or string or nil
- callback: callable (async version) or nil (sync version)
- err: nil or string
- success: boolean or nil

Equivalent to futimes(3).

See luv-constants for supported FS Modification Time constants.

Passing "now" or uv.constants.FS_UTIME_NOW as the atime or mtime sets the timestamp to the current time.

Passing nil, "omit", or uv.constants.FS_UTIME_OMIT as the atime or mtime leaves the timestamp untouched.

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_lutime({path} [, {atime}, {mtime}, {callback}]) uv.fs_lutime()

Parameters:
- path: string
- atime: number or string or nil
- mtime: number or string or nil
- callback: callable (async version) or nil (sync version)
- err: nil or string
- success: boolean or nil

Equivalent to lutimes(3).

See luv-constants for supported FS Modification Time constants.

Passing "now" or uv.constants.FS_UTIME_NOW as the atime or mtime sets the timestamp to the current time.

Passing nil, "omit", or uv.constants.FS_UTIME_OMIT as the atime or mtime leaves the timestamp untouched.

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_link({path}, {new_path} [, {callback}]) uv.fs_link()

Parameters:

- path: string
- new_path: string
- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - success: boolean or nil

Equivalent to link(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_symlink({path}, {new_path} [, {flags} [, {callback}]]) uv.fs_symlink()

Parameters:

- path: string
- new_path: string
- flags: table, integer, or nil
    - dir: boolean
    - junction: boolean
- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - success: boolean or nil

Equivalent to symlink(2). If the flags parameter is omitted, then the 3rd parameter will be treated as the callback.

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_readlink({path} [, {callback}]) uv.fs_readlink()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - path: string or nil

Equivalent to readlink(2).

Returns (sync version): string or fail

Returns (async version): uv_fs_t userdata

uv.fs_realpath({path} [, {callback}]) uv.fs_realpath()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
    - err: nil or string
    - path: string or nil

Equivalent to realpath(3).

Returns (sync version): string or fail

Returns (async version): uv_fs_t userdata

uv.fs_chown({path}, {uid}, {gid} [, {callback}]) uv.fs_chown()

Parameters:

- path: string
- uid: integer
- gid: integer
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to chown(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_fchown({fd}, {uid}, {gid} [, {callback}]) uv.fs_fchown()

Parameters:

- fd: integer
- uid: integer
- gid: integer
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to fchown(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_lchown({fd}, {uid}, {gid} [, {callback}]) uv.fs_lchown()

Parameters:

- fd: integer
- uid: integer
- gid: integer
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Equivalent to lchown(2).

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_copyfile({path}, {new_path} [, {flags} [, {callback}]]) uv.fs_copyfile()

Parameters:

- path: string

- new_path: string
- flags: table, integer, or nil
  - excl: boolean
  - ficlone: boolean
  - ficlone_force: boolean
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Copies a file from path to new_path. If the flags parameter is omitted, then the 3rd parameter will be treated as the callback.

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_opendir({path} [, {callback} [, {entries}]]) uv.fs_opendir()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - dir: luv_dir_t userdata or nil
- entries: integer or nil

Opens path as a directory stream. Returns a handle that the user can pass to uv.fs_readdir(). The entries parameter defines the maximum number of entries that should be returned by each call to uv.fs_readdir().

Returns (sync version): luv_dir_t userdata or fail

Returns (async version): uv_fs_t userdata

uv.fs_readdir({dir} [, {callback}]) uv.fs_readdir()

> method form dir:readdir([callback])

Parameters:

- dir: luv_dir_t userdata
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - entries: table or nil (see below)

Iterates over the directory stream luv_dir_t returned by a successful uv.fs_opendir() call. A table of data tables is returned where the number of entries n is equal to or less than the entries parameter used in the associated uv.fs_opendir() call.

Returns (sync version): table or fail

- [1, 2, 3, ..., n] : table
  - name : string
  - type : string

Returns (async version): uv_fs_t userdata

uv.fs_closedir({dir} [, {callback}]) uv.fs_closedir()

> method form dir:closedir([callback])

Parameters:

- dir: luv_dir_t userdata
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - success: boolean or nil

Closes a directory stream returned by a successful uv.fs_opendir() call.

Returns (sync version): boolean or fail

Returns (async version): uv_fs_t userdata

uv.fs_statfs({path} [, {callback}]) uv.fs_statfs()

Parameters:

- path: string
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - table or nil (see below)

Equivalent to statfs(2).

Returns table or nil

- type : integer
- bsize : integer
- blocks : integer
- bfree : integer
- bavail : integer
- files : integer
- ffree : integer
- frsize: integer or nil

THREAD POOL WORK SCHEDULING luv-thread-pool-work-scheduling

Libuv provides a threadpool which can be used to run user code and get notified in the loop thread. This threadpool is internally used to run all file system operations, as well as getaddrinfo and getnameinfo requests.

```
local function work_callback(a, b)
  return a + b
end

local function after_work_callback(c)
  print("The result is: " .. c)
end

local work = uv.new_work(work_callback, after_work_callback)

work:queue(1, 2)

-- output: "The result is: 3"
```

uv.new_work({work_callback}, {after_work_callback}) uv.new_work()

Parameters:

- work_callback: function or string
  - ...: threadargs passed to/from

uv.queue_work(work_ctx, ...)

- after_work_callback: function
  - ...: threadargs returned from work_callback

Creates and initializes a new luv_work_ctx_t (not uv_work_t).
work_callback is a Lua function or a string containing Lua code or bytecode dumped from a function. Returns the Lua userdata wrapping it.

Returns: luv_work_ctx_t userdata

uv.queue_work({work_ctx}, {...}) uv.queue_work()

> method form work_ctx:queue(...)

Parameters:

- work_ctx: luv_work_ctx_t userdata
- ...: threadargs

Queues a work request which will run work_callback in a new Lua state in a thread from the threadpool with any additional arguments from .... Values returned from work_callback are passed to after_work_callback, which is called in the main loop thread.

Returns: boolean or fail

DNS UTILITY FUNCTIONS luv-dns-utility-functions

uv.getaddrinfo({host}, {service} [, {hints} [, {callback}]]) uv.getaddrinfo()

Parameters:

- host: string or nil
- service: string or nil
- hints: table or nil
  - family: string or integer or nil
  - socktype: string or integer or nil
  - protocol: string or integer or nil
  - addrconfig: boolean or nil
  - v4mapped: boolean or nil
  - all: boolean or nil
  - numerichost: boolean or nil
  - passive: boolean or nil
  - numericserv: boolean or nil
  - canonname: boolean or nil
- callback: callable (async version) or nil (sync version)
  - err: nil or string

- addresses: table or nil (see below)

  Equivalent to getaddrinfo(3). Either node or service may
  be nil but not both.

  See luv-constants for supported address family input and
  output values.

  See luv-constants for supported socktype input and
  output values.

  When protocol is set to 0 or nil, it will be
  automatically chosen based on the socket's domain and type.
  When protocol is specified as a string, it will be looked up
  using the getprotobyname(3) function. Examples: "ip",
  "icmp", "tcp", "udp", etc.

  Returns (sync version): table or fail
- [1, 2, 3, ..., n] : table
  - addr : string
  - family : string
  - port : integer or nil
  - socktype : string
  - protocol : string
  - canonname : string or nil

  Returns (async version): uv_getaddrinfo_t userdata or fail

uv.getnameinfo({address} [, {callback}]) uv.getnameinfo()

  Parameters:
- address: table
  - ip: string or nil
  - port: integer or nil
  - family: string or integer or nil
- callback: callable (async version) or nil (sync
  version)
  - err: nil or string
  - host: string or nil
  - service: string or nil

  Equivalent to getnameinfo(3).

  See luv-constants for supported address family input values.

  Returns (sync version): string, string or fail

  Returns (async version): uv_getnameinfo_t userdata or fail

THREADING AND SYNCHRONIZATION UTILITIES luv-threading-and-synchronization-utilities

Libuv provides cross-platform implementations for multiple threading and
synchronization primitives. The API largely follows the pthreads API.

uv.new_thread([{options},] {entry}, {...}) uv.new_thread()

  Parameters:
- options: table or nil
  - stack_size: integer or nil
- entry: function or string

- ...: threadargs passed to entry

Creates and initializes a luv_thread_t (not uv_thread_t). Returns the Lua userdata wrapping it and asynchronously executes entry, which can be either a Lua function or a string containing Lua code or bytecode dumped from a function. Additional arguments ... are passed to the entry function and an optional options table may be provided. Currently accepted option fields are stack_size.

Returns: luv_thread_t userdata

Note: unsafe, please make sure that the thread's end of life is before Lua state is closed.

uv.thread_equal({thread}, {other_thread}) uv.thread_equal()

> method form thread:equal(other_thread)

Parameters:

- thread: luv_thread_t userdata
- other_thread: luv_thread_t userdata

Returns a boolean indicating whether two threads are the same. This function is equivalent to the __eq metamethod.

Returns: boolean

uv.thread_setaffinity()

uv.thread_setaffinity({thread}, {affinity} [, {get_old_affinity}])

> method form thread:setaffinity(affinity, [get_old_affinity])

Parameters:

- thread: luv_thread_t userdata
- affinity: table
  - [1, 2, 3, ..., n] : boolean
- get_old_affinity: boolean

Sets the specified thread's affinity setting.

affinity must be a table where each of the keys are a CPU number and the values are booleans that represent whether the thread should be eligible to run on that CPU. If the length of the affinity table is not greater than or equal to uv.cpumask_size(), any CPU numbers missing from the table will have their affinity set to false. If setting the affinity of more than uv.cpumask_size() CPUs is desired, affinity must be an array-like table with no gaps, since #affinity will be used as the cpumask_size if it is greater than uv.cpumask_size().

If get_old_affinity is true, the previous affinity settings for the thread will be returned. Otherwise, true is returned after a successful call.

Note: Thread affinity setting is not atomic on Windows. Unsupported on macOS.

Returns: table or boolean or fail

- [1, 2, 3, ..., n] : boolean

uv.thread_getaffinity({thread} [, {mask_size}]) uv.thread_getaffinity()

> method form thread:getaffinity([mask_size])

Parameters:

- thread: luv_thread_t userdata
- mask_size: integer

Gets the specified thread's affinity setting.

If mask_size is provided, it must be greater than or equal to uv.cpumask_size(). If the mask_size parameter is omitted, then the return of uv.cpumask_size() will be used. Returns an array-like table where each of the keys correspond to a CPU number and the values are booleans that represent whether the thread is eligible to run on that CPU.

Note: Thread affinity getting is not atomic on Windows. Unsupported on macOS.

Returns: table or fail

- [1, 2, 3, ..., n] : boolean

uv.thread_getcpu() uv.thread_getcpu()

Gets the CPU number on which the calling thread is running.

Note: The first CPU will be returned as the number 1, not 0. This allows for the number to correspond with the table keys used in uv.thread_getaffinity and uv.thread_setaffinity.

Returns: integer or fail

uv.thread_setpriority({thread}, {priority}) uv.thread.setpriority()

> method form thread:setpriority(priority)

Parameters:

- thread: luv_thread_t userdata
- priority: number

Sets the specified thread's scheduling priority setting. It requires elevated privilege to set specific priorities on some platforms. The priority can be set to the following constants:

- uv.constants.THREAD_PRIORITY_HIGHEST
- uv.constants.THREAD_PRIORITY_ABOVE_NORMAL
- uv.constants.THREAD_PRIORITY_NORMAL
- uv.constants.THREAD_PRIORITY_BELOW_NORMAL
- uv.constants.THREAD_PRIORITY_LOWEST

Returns: boolean or fail

uv.thread_getpriority({thread}) uv.thread.getpriority()

> method form thread:getpriority()

Parameters:

- thread: luv_thread_t userdata

Gets the thread's priority setting.

Retrieves the scheduling priority of the specified thread. The returned priority value is platform dependent.

For Linux, when schedule policy is SCHED_OTHER (default), priority is 0.

Returns: number or fail

uv.thread_self() uv.thread_self()

Returns the handle for the thread in which this is called.

Returns: luv_thread_t

uv.thread_join({thread}) uv.thread_join()

> method form thread:join()

Parameters:

- thread: luv_thread_t userdata

Waits for the thread to finish executing its entry function.

Returns: boolean or fail

uv.thread_detach({thread}) uv.thread_detach()

> method form thread:detach()

Parameters:

- thread: luv_thread_t userdata

Detaches a thread. Detached threads automatically release their resources upon termination, eliminating the need for the application to call uv.thread_join.

Returns: boolean or fail

uv.thread_setname({name}) uv.thread_setname()

Parameters:

- name: string

Sets the name of the current thread. Different platforms define different limits on the max number of characters a thread name can be: Linux, IBM i (16), macOS (64), Windows (32767), and NetBSD (32), etc. The name will be truncated if name is larger than the limit of the platform.

Returns: 0 or fail

uv.thread_getname({thread}) uv.thread_getname()

> method form thread:getname()

Parameters:

- thread: luv_thread_t userdata

Gets the name of the thread specified by thread.

Returns: string or fail

uv.sleep({msec}) uv.sleep()

Parameters:

- msec: integer

Pauses the thread in which this is called for a number of milliseconds.

Returns: Nothing.

uv.new_sem([{value}]) uv.new_sem()

Parameters:

- value: integer or nil

Creates a new semaphore with the specified initial value. A semaphore is safe to share across threads. It represents an unsigned integer value that can incremented and decremented atomically but any attempt to make it negative will "wait" until the value can be decremented by another thread incrementing it.

The initial value must be a non-negative integer.

Returns: luv_sem_t userdata or fail

Note: A semaphore must be shared between threads, any uv.sem_wait() on a single thread that blocks will deadlock.

uv.sem_post({sem}) uv.sem_post()

> method form sem:post()

Parameters:

- sem: luv_sem_t userdata

Increments (unlocks) a semaphore, if the semaphore's value consequently becomes greater than zero then another thread blocked in a sem_wait call will be woken and proceed to decrement the semaphore.

Returns: Nothing.

uv.sem_wait({sem}) uv.sem_wait()

> method form sem:wait()

Parameters:

- sem: luv_sem_t userdata

Decrements (locks) a semaphore, if the semaphore's value is greater than zero then the value is decremented and the call returns immediately. If the semaphore's value is zero then the call blocks until the semaphore's value rises above zero or the call is interrupted by a signal.

Returns: Nothing.

uv.sem_trywait({sem}) uv.sem_trywait()

> method form sem:trywait()

Parameters:

- sem: luv_sem_t userdata

The same as uv.sem_wait() but returns immediately if the semaphore is not available.

If the semaphore's value was decremented then true is returned, otherwise the semaphore has a value of zero and false is returned.

Returns: boolean

MISCELLANEOUS UTILITIES luv-miscellaneous-utilities

uv.exepath() uv.exepath()

Returns the executable path.

Returns: string or fail

uv.cwd() uv.cwd()

Returns the current working directory.

Returns: string or fail

uv.chdir({cwd}) uv.chdir()

Parameters:

- cwd: string

Sets the current working directory with the string cwd.

Returns: 0 or fail

uv.get_process_title() uv.get_process_title()

Returns the title of the current process.

Returns: string or fail

uv.set_process_title({title}) uv.set_process_title()

Parameters:

- title: string

Sets the title of the current process with the string title.

Returns: 0 or fail

uv.get_total_memory() uv.get_total_memory()

Returns the current total system memory in bytes.

Returns: number

uv.get_free_memory() uv.get_free_memory()

Returns the current free system memory in bytes.

Returns: number

uv.get_constrained_memory() uv.get_constrained_memory()

Gets the amount of memory available to the process in bytes based on limits imposed by the OS. If there is no such constraint, or the constraint is unknown, 0 is returned. Note that it is not unusual for this value to be less than or greater than the total system memory.

Returns: number

uv.get_available_memory() uv.get_available_memory()

Gets the amount of free memory that is still available to the process (in bytes). This differs from uv.get_free_memory() in that it takes into account any limits imposed by the OS. If there is no such constraint, or the constraint is unknown, the amount returned will be identical to uv.get_free_memory().

Returns: number

uv.resident_set_memory() uv.resident_set_memory()

Returns the resident set size (RSS) for the current process.

Returns: integer or fail

uv.getrusage() uv.getrusage()

Returns the resource usage.

Returns: table or fail

- utime : table (user CPU time used)
    - sec : integer
    - usec : integer
- stime : table (system CPU time used)
    - sec : integer
    - usec : integer
- maxrss : integer (maximum resident set size)
- ixrss : integer (integral shared memory size)
- idrss : integer (integral unshared data size)

- isrss : integer (integral unshared stack size)
- minflt : integer (page reclaims (soft page faults))
- majflt : integer (page faults (hard page faults))
- nswap : integer (swaps)
- inblock : integer (block input operations)
- oublock : integer (block output operations)
- msgsnd : integer (IPC messages sent)
- msgrcv : integer (IPC messages received)
- nsignals : integer (signals received)
- nvcsw : integer (voluntary context switches)
- nivcsw : integer (involuntary context switches)

uv.getrusage_thread() uv.getrusage_thread()

Gets the resource usage measures for the calling thread.

Note: Not supported on all platforms. May return ENOTSUP.

On macOS and Windows not all fields are set (the unsupported fields are filled with zeroes).

Returns: table or fail

- utime : table (user CPU time used)
  - sec : integer
  - usec : integer
- stime : table (system CPU time used)
  - sec : integer
  - usec : integer
- maxrss : integer (maximum resident set size)
- ixrss : integer (integral shared memory size)
- idrss : integer (integral unshared data size)
- isrss : integer (integral unshared stack size)
- minflt : integer (page reclaims (soft page faults))
- majflt : integer (page faults (hard page faults))
- nswap : integer (swaps)
- inblock : integer (block input operations)
- oublock : integer (block output operations)
- msgsnd : integer (IPC messages sent)

- msgrcv : integer (IPC messages received)
- nsignals : integer (signals received)
- nvcsw : integer (voluntary context switches)
- nivcsw : integer (involuntary context switches)

uv.available_parallelism() uv.available_parallelism()

Returns an estimate of the default amount of parallelism a program should use. Always returns a non-zero value.

On Linux, inspects the calling thread's CPU affinity mask to determine if it has been pinned to specific CPUs.

On Windows, the available parallelism may be underreported on systems with more than 64 logical CPUs.

On other platforms, reports the number of CPUs that the operating system considers to be online.

Returns: integer

uv.cpu_info() uv.cpu_info()

Returns information about the CPU(s) on the system as a table of tables for each CPU found.

Returns: table or fail

- [1, 2, 3, ..., n] : table
  - model : string
  - speed : number
  - times : table
    - user : number
    - nice : number
    - sys : number
    - idle : number
    - irq : number

uv.cpumask_size() uv.cpumask_size()

Returns the maximum size of the mask used for process/thread affinities, or ENOTSUP if affinities are not supported on the current platform.

Returns: integer or fail

uv.getpid() uv.getpid()

DEPRECATED: Please use uv.os_getpid() instead.

uv.getuid() uv.getuid()

Returns the user ID of the process.

Returns: integer

Note: This is not a libuv function and is not supported on Windows.

uv.getgid() uv.getgid()

Returns the group ID of the process.

Returns: integer

Note: This is not a libuv function and is not supported on Windows.

uv.setuid({id}) uv.setuid()

Parameters:

- id: integer

Sets the user ID of the process with the integer id.

Returns: Nothing.

Note: This is not a libuv function and is not supported on Windows.

uv.setgid({id}) uv.setgid()

Parameters:

- id: integer

Sets the group ID of the process with the integer id.

Returns: Nothing.

Note: This is not a libuv function and is not supported on Windows.

uv.hrtime() uv.hrtime()

Returns a current high-resolution time in nanoseconds as a number. This is relative to an arbitrary time in the past. It is not related to the time of day and therefore not subject to clock drift. The primary use is for measuring time between intervals.

Returns: integer

uv.clock_gettime({clock_id}) uv.clock_gettime()

Parameters:

- clock_id: string

Obtain the current system time from a high-resolution real-time or monotonic clock source. clock_id can be the string "monotonic" or "realtime".

The real-time clock counts from the UNIX epoch (1970-01-01) and is subject to time adjustments; it can jump back in time.

The monotonic clock counts from an arbitrary point in the past and never jumps back in time.

Returns: table or fail

- sec: integer
- nsec: integer

uv.uptime() uv.uptime()

Returns the current system uptime in seconds.

Returns: number or fail

uv.print_all_handles() uv.print_all_handles()

Prints all handles associated with the main loop to stderr. The format is [flags] handle-type handle-address . Flags are R for referenced, A for active and I for internal.

Returns: Nothing.

Note: This is not available on Windows.

WARNING: This function is meant for ad hoc debugging, there are no API/ABI stability guarantees.

uv.print_active_handles() uv.print_active_handles()

The same as uv.print_all_handles() except only active handles are printed.

Returns: Nothing.

Note: This is not available on Windows.

WARNING: This function is meant for ad hoc debugging, there are no API/ABI stability guarantees.

uv.guess_handle({fd}) uv.guess_handle()

Parameters:

- fd: integer

Used to detect what type of stream should be used with a given file descriptor fd. Usually this will be used during initialization to guess the type of the stdio streams.

Returns: string

uv.gettimeofday() uv.gettimeofday()

Cross-platform implementation of gettimeofday(2). Returns the seconds and microseconds of a unix time as a pair.

Returns: integer, integer or fail

uv.interface_addresses() uv.interface_addresses()

Returns address information about the network interfaces on the system in a table. Each table key is the name of the interface while each associated value is an array of address information where fields are ip, family, netmask, internal, and mac.

See luv-constants for supported address family output values.

Returns: table or fail

- [name(s)] : table
  - ip : string
  - family : string
  - netmask : string
  - internal : boolean
  - mac : string

uv.if_indextoname({ifindex}) uv.if_indextoname()

Parameters:

- ifindex: integer

IPv6-capable implementation of if_indextoname(3).

Returns: string or fail

uv.if_indextoiid({ifindex}) uv.if_indextoiid()

Parameters:

- ifindex: integer

Retrieves a network interface identifier suitable for use in an IPv6 scoped address. On Windows, returns the numeric ifindex as a string. On all other platforms, uv.if_indextoname() is used.

Returns: string or fail

uv.loadavg() uv.loadavg()

Returns the load average as a triad. Not supported on Windows.

Returns: number, number, number

uv.os_uname() uv.os_uname()

Returns system information.

Returns: table

- sysname : string
- release : string
- version : string
- machine : string

uv.os_gethostname() uv.os_gethostname()

Returns the hostname.

Returns: string

uv.os_getenv({name} [, {size}]) uv.os_getenv()

Parameters:

- name: string
- size: integer (default = LUAL_BUFFERSIZE)

Returns the environment variable specified by name as string. The internal buffer size can be set by defining size. If omitted, LUAL_BUFFERSIZE is used. If the environment variable exceeds the storage available in the internal buffer, ENOBUFS is returned. If no matching environment variable exists, ENOENT is returned.

Returns: string or fail

WARNING: This function is not thread safe.

uv.os_setenv({name}, {value}) uv.os_setenv()

Parameters:

- name: string

- value: string

Sets the environmental variable specified by name with the string value.

Returns: boolean or fail

WARNING: This function is not thread safe.

uv.os_unsetenv({name}) uv.os_unsetenv()

Parameters:

- name: string

Unsets the environmental variable specified by name.

Returns: boolean or fail

WARNING: This function is not thread safe.

uv.os_environ() uv.os_environ()

Returns all environmental variables as a dynamic table of names associated with their corresponding values.

Returns: table

WARNING: This function is not thread safe.

uv.os_homedir() uv.os_homedir()

Returns: string or fail

WARNING: This function is not thread safe.

uv.os_tmpdir() uv.os_tmpdir()

Returns: string or fail

WARNING: This function is not thread safe.

uv.os_get_passwd() uv.os_get_passwd()

Returns password file information.

Returns: table or fail

- username : string

- uid : integer? (nil on Windows)

- gid : integer? (nil on Windows)

- shell : string?(nil` on Windows)

- homedir : string

uv.os_getpid() uv.os_getpid()

Returns the current process ID.

Returns: number

uv.os_getppid() uv.os_getppid()

Returns the parent process ID.

Returns: number

uv.os_getpriority({pid}) uv.os_getpriority()

Parameters:

- pid: integer

Returns the scheduling priority of the process specified by pid.

Returns: number or fail

uv.os_setpriority({pid}, {priority}) uv.os_setpriority()

Parameters:

- pid: integer

- priority: integer

Sets the scheduling priority of the process specified by pid. The priority range is between -20 (high priority) and 19 (low priority).

Returns: boolean or fail

uv.random({len}, {flags} [, {callback}]) uv.random()

Parameters:

- len: integer

- flags: nil (see below)
- callback: callable (async version) or nil (sync version)
  - err: nil or string
  - bytes: string or nil

Fills a string of length len with cryptographically strong random bytes acquired from the system CSPRNG. flags is reserved for future extension and must currently be nil or 0 or {}.

Short reads are not possible. When less than len random bytes are available, a non-zero error value is returned or passed to the callback. If the callback is omitted, this function is completed synchronously.

The synchronous version may block indefinitely when not enough entropy is available. The asynchronous version may not ever finish when the system is low on entropy.

Returns (sync version): string or fail

Returns (async version): 0 or fail

uv.translate_sys_error({errcode}) uv.translate_sys_error()

Parameters:
- errcode: integer

Returns the libuv error message and error name (both in string form, see err and name in luv-error-handling) equivalent to the given platform dependent error code: POSIX error codes on Unix (the ones stored in errno), and Win32 error codes on Windows (those returned by GetLastError() or WSAGetLastError()).

Returns: string, string or nil

METRICS OPERATIONS luv-metrics-operations

uv.metrics_idle_time() uv.metrics_idle_time()

Retrieve the amount of time the event loop has been idle in the kernel's event provider (e.g. epoll_wait). The call is thread safe.

The return value is the accumulated time spent idle in the kernel's event provider starting from when the uv_loop_t was configured to collect the idle time.

Note: The event loop will not begin accumulating the event provider's idle time until calling loop_configure with "metrics_idle_time".

Returns: number

uv.metrics_info() uv.metrics_info()

Get the metrics table from current set of event loop metrics. It is recommended to retrieve these metrics in a prepare callback (see uv.new_prepare(), uv.prepare_start()) in order to make sure there are no inconsistencies with the metrics counters.

Returns: table

- loop_count : integer
- events : integer
- events_waiting : integer

STRING MANIPULATION FUNCTIONS luv-string-manipulation

These string utilities are needed internally for dealing with Windows, and are exported to allow clients to work uniformly with this data when the libuv API is not complete.

Notes:
1. New in luv version 1.49.0.
2. See the WTF-8 spec (https://simonsapin.github.io/wtf-8/) for information

about WTF-8.

3. Luv uses Lua-style strings, which means that all inputs and return values (UTF-8 or UTF-16 strings) do not include a NUL terminator.

uv.utf16_length_as_wtf8({utf16}) uv.utf16_length_as_wtf8()

Get the length (in bytes) of a UTF-16 (or UCS-2) string utf16 value after converting it to WTF-8. The endianness of the UTF-16 (or UCS-2) string is assumed to be the same as the native endianness of the platform.

Parameters:

- utf16: string

Returns: integer

uv.utf16_to_wtf8({utf16}) uv.utf16_to_wtf8()

Convert UTF-16 (or UCS-2) string utf16 to UTF-8 string. The endianness of the UTF-16 (or UCS-2) string is assumed to be the same as the native endianness of the platform.

Parameters:

- utf16: string

Returns: string

uv.wtf8_length_as_utf16({wtf16}) uv.wtf8_length_as_utf16()

Get the length (in UTF-16 code units) of a WTF-8 wtf8 value after converting it to UTF-16 (or UCS-2).

Note: The number of bytes needed for a UTF-16 (or UCS-2) string is <number of code units> * 2.

Parameters:

- wtf8: string

Returns: integer

uv.wtf8_to_utf16({wtf16}) uv.wtf8_to_utf16()

Convert WTF-8 string in wtf8 to UTF-16 (or UCS-2) string. The endianness of the UTF-16 (or UCS-2) string is assumed to be the same as the native endianness of the platform.

Parameters:

- wtf8: string

Returns: string

CREDITS luv-credits

This document is a reformatted version of the LUV documentation, up-to-date with commit dcd1a1c (23 Aug 2023) of the luv repository https://github.com/luvit/luv/commit/dcd1a1cad5b05634a7691402d6ca2f214fb4ae76.

Based on https://github.com/nanotee/luv-vimdocs with kind permission.

Key mapping, abbreviations and user-defined commands.

This subject is introduced in sections 05.3, 24.7 and 40.1 of the user manual.

1. Key mapping

key-mapping mapping

Key mapping is used to change the meaning of typed keys. The most common use is to define a sequence of commands for a function key. Example:

```
:map <F2> a<C-R>=strftime("%c")<CR><Esc>
```

This appends the current date and time after the cursor (in <> notation <>).

1.1 MAP COMMANDS

:map-commands

There are commands to enter new mappings, remove mappings and list mappings. See map-overview for the various forms of "map" and their relationships with modes.

{lhs} means left-hand-side {lhs}
{rhs} means right-hand-side {rhs}

:map {lhs} {rhs} mapmode-nvo :map

:nm[ap] {lhs} {rhs} mapmode-n :nm :nmap
:vm[ap] {lhs} {rhs} mapmode-v :vm :vmap
:xm[ap] {lhs} {rhs} mapmode-x :xm :xmap
:smap {lhs} {rhs} mapmode-s :smap

:om[ap] {lhs} {rhs} mapmode-o :om :omap
:map! {lhs} {rhs} mapmode-ic :map!

:im[ap] {lhs} {rhs} mapmode-i :im :imap
:lm[ap] {lhs} {rhs} mapmode-l :lm :lma :lmap
:cm[ap] {lhs} {rhs} mapmode-c :cm :cmap
:tma[p] {lhs} {rhs} mapmode-t :tma :tmap

Map the key sequence {lhs} to {rhs} for the modes where the map command applies. The result, including {rhs}, is then further scanned for mappings. This allows for nested and recursive use of mappings.
Note: Trailing spaces are included in the {rhs}, because space is a valid Normal mode command.
See map-trailing-white.

:nore :norem
:no[remap] {lhs} {rhs} mapmode-nvo :no :noremap :nor
:nn[oremap] {lhs} {rhs} mapmode-n :nn :nnoremap
:vn[oremap] {lhs} {rhs} mapmode-v :vn :vnoremap
:xn[oremap] {lhs} {rhs} mapmode-x :xn :xnoremap
:snor[emap] {lhs} {rhs} mapmode-s :snor :snore :snoremap
:ono[remap] {lhs} {rhs} mapmode-o :ono :onoremap
:no[remap]! {lhs} {rhs} mapmode-ic :no! :noremap!
:ino[remap] {lhs} {rhs} mapmode-i :ino :inor :inoremap
:ln[oremap] {lhs} {rhs} mapmode-l :ln :lnoremap
:cno[remap] {lhs} {rhs} mapmode-c :cno :cnor :cnoremap
:tno[remap] {lhs} {rhs} mapmode-t :tno :tnoremap

Map the key sequence {lhs} to {rhs} for the modes where the map command applies. Disallow mapping of {rhs}, to avoid nested and recursive mappings. Often used to redefine a command.
Note: Keys in {rhs} also won't trigger abbreviation, with the exception of i_CTRL-] and c_CTRL-].
Note: When <Plug> appears in the {rhs} this part is always applied even if remapping is disallowed.

:unm[ap] {lhs} mapmode-nvo :unm :unmap
:nun[map] {lhs} mapmode-n :nun :nunmap
:vu[nmap] {lhs} mapmode-v :vu :vunmap
:xu[nmap] {lhs} mapmode-x :xu :xunmap
:sunm[ap] {lhs} mapmode-s :sunm :sunmap
:ou[nmap] {lhs} mapmode-o :ou :ounmap
:unm[ap]! {lhs} mapmode-ic :unm! :unmap!
:iu[nmap] {lhs} mapmode-i :iu :iunmap
:lu[nmap] {lhs} mapmode-l :lu :lunmap
:cu[nmap] {lhs} mapmode-c :cu :cun :cunmap
:tunma[p] {lhs} mapmode-t :tunma :tunmap

Remove the mapping of {lhs} for the modes where the map command applies. The mapping may remain defined for other modes where it applies.
If no mapping with {lhs} exists, it also works when {lhs} matches the {rhs} of a mapping (see vim.keymap.del() to avoid that). This is for when an abbreviation applied.
Note: Trailing spaces are included in the {lhs}.
See map-trailing-white.

:mapc[lear] mapmode-nvo :mapc :mapclear
:nmapc[lear] mapmode-n :nmapc :nmapclear
:vmapc[lear] mapmode-v :vmapc :vmapclear
:xmapc[lear] mapmode-x :xmapc :xmapclear
:smapc[lear] mapmode-s :smapc :smapclear

:omapc[lear]		mapmode-o		:omapc	:omapclear
:mapc[lear]!		mapmode-ic		:mapc!	:mapclear!
:imapc[lear]		mapmode-i		:imapc	:imapclear
:lmapc[lear]		mapmode-l		:lmapc	:lmapclear
:cmapc[lear]		mapmode-c		:cmapc	:cmapclear
:tmapc[lear]		mapmode-t		:tmapc	:tmapclear

Remove ALL mappings for the modes where the map
command applies.
Use the <buffer> argument to remove buffer-local
mappings :map-<buffer>
Warning: This also removes the default-mappings.

:map		mapmode-nvo
:nm[ap]		mapmode-n
:vm[ap]		mapmode-v
:xm[ap]		mapmode-x
:sm[ap]		mapmode-s
:om[ap]		mapmode-o
:map!		mapmode-ic
:im[ap]		mapmode-i
:lm[ap]		mapmode-l
:cm[ap]		mapmode-c
:tma[p]		mapmode-t

List all key mappings for the modes where the map
command applies. Note that ":map" and ":map!" are
used most often, because they include the other modes.

:map {lhs}		mapmode-nvo		:map_l

:nm[ap] {lhs}		mapmode-n		:nmap_l

:vm[ap] {lhs}		mapmode-v		:vmap_l

:xm[ap] {lhs}		mapmode-x		:xmap_l

:sm[ap] {lhs}		mapmode-s		:smap_l

:om[ap] {lhs}		mapmode-o		:omap_l

:map! {lhs}		mapmode-ic		:map_l!

:im[ap] {lhs}		mapmode-i		:imap_l

:lm[ap] {lhs}		mapmode-l		:lmap_l

:cm[ap] {lhs}		mapmode-c		:cmap_l

:tma[p] {lhs}		mapmode-t		:tmap_l

List the key mappings for the key sequences starting
with {lhs} in the modes where the map command applies.

These commands are used to map a key or key sequence to a string of
characters. You can use this to put command sequences under function keys,
translate one key into another, etc. See :mkexrc for how to save and
restore the current mappings.

map-ambiguous

When two mappings start with the same sequence of characters, they are
ambiguous. Example:

```
:imap aa foo
:imap aaa bar
```

When Vim has read "aa", it will need to get another character to be able to
decide if "aa" or "aaa" should be mapped. This means that after typing "aa"
that mapping won't get expanded yet, Vim is waiting for another character.
If you type a space, then "foo" will get inserted, plus the space. If you
type "a", then "bar" will get inserted.

Trailing white space

map-trailing-white

This unmap command does NOT work:

```
:map @@ foo
:unmap @@ | print
```

Because it tries to unmap "@@ ", including the white space before the command
separator "|". Other examples with trailing white space:

```
unmap @@
unmap @@     " comment
```

An error will be issued, which is very hard to identify, because the ending
whitespace character in unmap @@ is not visible.

A generic solution is to put the command separator "|" right after the mapped
keys. After that white space and a comment may follow:

```
unmap @@|    " comment
```

1.2 SPECIAL ARGUMENTS

:map-arguments

"<buffer>", "<nowait>", "<silent>", "<script>", "<expr>" and
"<unique>" can be used in any order. They must appear right after the
command, before any other arguments.

:map-local :map-<buffer> :map-buffer
E224 E225

If the first argument to one of these commands is "<buffer>" the mapping will
be effective in the current buffer only. Example:

```
:map <buffer>  ,w  /[.,;]<CR>
```

Then you can map ",w" to something else in another buffer:

```
:map <buffer>  ,w  /[#&!]<CR>
```

The local buffer mappings are used before the global ones. See <nowait> below
to make a short local mapping take effect when a longer global one exists.
The "<buffer>" argument can also be used to clear mappings:

```
:unmap <buffer> ,w
:mapclear <buffer>
```

Local mappings are also cleared when a buffer is deleted, but not when it is
unloaded. Just like local option values.
Also see map-precedence.

:map-<nowait> :map-nowait

When defining a buffer-local mapping for "," there may be a global mapping
that starts with ",". Then you need to type another character for Vim to know
whether to use the "," mapping or the longer one. To avoid this add the
<nowait> argument. Then the mapping will be used when it matches, Vim does
not wait for more characters to be typed. However, if the characters were
already typed they are used.
Note that this works when the <nowait> mapping fully matches and is found
before any partial matches. This works when:

- There is only one matching buffer-local mapping, since these are always
  found before global mappings.
- There is another buffer-local mapping that partly matches, but it is
  defined earlier (last defined mapping is found first).

:map-<silent> :map-silent

To define a mapping which will not be echoed on the command line, add
"<silent>" as the first argument. Example:

```
:map <silent> ,h /Header<CR>
```

The search string will not be echoed when using this mapping. Messages from
the executed command are still given though. To shut them up too, add a
":silent" in the executed command:

```
:map <silent> ,h :exe ":silent normal /Header\r"<CR>
```

Note that the effect of a command might also be silenced, e.g., when the
mapping selects another entry for command line completion it won't be
displayed.
Prompts will still be given, e.g., for inputdialog().
Using "<silent>" for an abbreviation is possible, but will cause redrawing of
the command line to fail.

:map-<script> :map-script

If the first argument to one of these commands is "<script>" and it is used to
define a new mapping or abbreviation, the mapping will only remap characters
in the {rhs} using mappings that were defined local to a script, starting with
"<SID>". This can be used to avoid that mappings from outside a script
interfere (e.g., when CTRL-V is remapped in mswin.vim), but do use other
mappings defined in the script.
Note: ":map <script>" and ":noremap <script>" do the same thing. The
"<script>" overrules the command name. Using ":noremap <script>" is
preferred, because it's clearer that remapping is (mostly) disabled.

:map-<unique> :map-unique E226 E227

If the first argument to one of these commands is "<unique>" and it is used to
define a new mapping or abbreviation, the command will fail if the mapping or
abbreviation already exists. Example:

```
:map <unique> ,w  /[#&!]<CR>
```

When defining a local mapping, there will also be a check if a global map
already exists which is equal.
Example of what will fail:

```
:map ,w  /[#&!]<CR>
:map <buffer> <unique> ,w  /[.,;]<CR>
```

If you want to map a key and then have it do what it was originally mapped to,
have a look at maparg().

:map-<expr> :map-expression

If the first argument to one of these commands is "<expr>" and it is used to
define a new mapping or abbreviation, the argument is an expression. The
expression is evaluated to obtain the {rhs} that is used. Example:

```
:inoremap <expr> . <SID>InsertDot()
```

The result of the s:InsertDot() function will be inserted. It could check the
text before the cursor and start omni completion when some condition is met.
Using a script-local function is preferred, to avoid polluting the global
namespace. Use <SID> in the RHS so that the script that the mapping was
defined in can be found.

For abbreviations v:char is set to the character that was typed to trigger
the abbreviation. You can use this to decide how to expand the {lhs}. You
should not either insert or change the v:char.

In case you want the mapping to not do anything, you can have the expression
evaluate to an empty string. If something changed that requires Vim to
go through the main loop (e.g. to update the display), return "\<Ignore>".
This is similar to "nothing" but makes Vim return from the loop that waits for
input.

Keep in mind that the expression may be evaluated when looking for
typeahead, before the previous command has been executed. For example:

```
func StoreColumn()
  let g:column = col('.')
  return 'x'
endfunc
nnoremap <expr> x StoreColumn()
nmap ! f!x
```

You will notice that g:column has the value from before executing "f!",
because "x" is evaluated before "f!" is executed.
This can be solved by inserting <Ignore> before the character that is
expression-mapped:

```
nmap ! f!<Ignore>x
```

Be very careful about side effects! The expression is evaluated while
obtaining characters, you may very well make the command dysfunctional.
Therefore the following is blocked for <expr> mappings:

- Changing the buffer text textlock.
- Editing another buffer.
- The :normal command.
- Moving the cursor is allowed, but it is restored afterwards.
- If the cmdline is changed, the old text and cursor position are restored.

  If you want the mapping to do any of these let the returned characters do
  that, or use a <Cmd> mapping instead.

You can use getchar(), it consumes typeahead if there is any. E.g., if you
have these mappings:

```
inoremap <expr> <C-L> nr2char(getchar())
inoremap <expr> <C-L>x "foo"
```

If you now type CTRL-L nothing happens yet, Vim needs the next character to
decide what mapping to use. If you type 'x' the second mapping is used and
"foo" is inserted. If you type any other key the first mapping is used,
getchar() gets the typed key and returns it.

Here is an example that inserts a list number that increases:

```
let counter = 0
inoremap <expr> <C-L> ListItem()
inoremap <expr> <C-R> ListReset()

func ListItem()
  let g:counter += 1
  return g:counter .. '. '
endfunc

func ListReset()
  let g:counter = 0
  return ''
endfunc
```

CTRL-L inserts the next number, CTRL-R resets the count. CTRL-R returns an empty string, so that nothing is inserted.

Note that using 0x80 as a single byte before other text does not work, it will be seen as a special key.

<Cmd> :map-cmd

The <Cmd> pseudokey begins a "command mapping", which executes the command directly without changing modes. Where you might use ":…<CR>" in the {rhs} of a mapping, you can instead use "<Cmd>…<CR>". Example:

```
noremap x <Cmd>echo mode(1)<CR>
```

This is more flexible than :<C-U> in Visual and Operator-pending mode, or <C-O>: in Insert mode, because the commands are executed directly in the current mode, instead of always going to Normal mode. Visual mode is preserved, so tricks with gv are not needed. Commands can be invoked directly in Command-line mode (which would otherwise require timer hacks). Example of using <Cmd> halfway Insert mode:

```
nnoremap <F3> aText <Cmd>echo mode(1)<CR> Added<Esc>
```

Unlike <expr> mappings, there are no special restrictions on the <Cmd> command: it is executed as if an (unrestricted) autocommand was invoked or an async event was processed.

Note:

- Because <Cmd> avoids mode-changes (unlike ":") it does not trigger CmdlineEnter and CmdlineLeave events. This helps performance.
- For the same reason, keycodes like <C-R><C-W> are interpreted as plain, unmapped keys.
- The command is not echo'd, no need for <silent>.
- The {rhs} is not subject to abbreviations nor to other mappings, even if the mapping is recursive.
- In Visual mode you can use line('v') and col('v') to get one end of the Visual area, the cursor is at the other end.

E1255 E1136

<Cmd> commands must terminate, that is, they must be followed by <CR> in the {rhs} of the mapping definition. Command-line mode is never entered. To use a literal "<" in the {rhs}, use <lt>.

1.3 MAPPING AND MODES :map-modes

mapmode-nvo mapmode-n mapmode-v mapmode-o mapmode-t

There are seven sets of mappings

- For Normal mode: When typing commands.
- For Visual mode: When typing commands while the Visual area is highlighted.
- For Select mode: like Visual mode but typing text replaces the selection.
- For Operator-pending mode: When an operator is pending (after "d", "y", "c", etc.). See below: omap-info.
- For Insert mode. These are also used in Replace mode.
- For Command-line mode: When entering a ":" or "/" command.

- For Terminal mode: When typing in a :terminal buffer.

Special case: While typing a count for a command in Normal mode, mapping zero is disabled. This makes it possible to map zero without making it impossible to type a count with a zero.

map-overview map-modes

Overview of which map command works in which mode. More details below.

```
COMMANDS                    MODES
:map   :noremap  :unmap     Normal, Visual, Select, Operator-pending
:nmap  :nnoremap :nunmap    Normal
:vmap  :vnoremap :vunmap    Visual and Select
:smap  :snoremap :sunmap    Select
:xmap  :xnoremap :xunmap    Visual
:omap  :onoremap :ounmap    Operator-pending
:map!  :noremap! :unmap!    Insert and Command-line
:imap  :inoremap :iunmap    Insert
:lmap  :lnoremap :lunmap    Insert, Command-line, Lang-Arg
:cmap  :cnoremap :cunmap    Command-line
:tmap  :tnoremap :tunmap    Terminal
```

Same information in a table:

map-table

```
Mode  | Norm | Ins | Cmd | Vis | Sel | Opr | Term | Lang |
Command        +------+-----+-----+-----+-----+-----+------+------+
[nore]map      | yes  |  -  |  -  | yes | yes | yes |  -   |  -   |
n[nore]map     | yes  |  -  |  -  |  -  |  -  |  -  |  -   |  -   |
[nore]map!     |  -   | yes | yes |  -  |  -  |  -  |  -   |  -   |
i[nore]map     |  -   | yes |  -  |  -  |  -  |  -  |  -   |  -   |
c[nore]map     |  -   |  -  | yes |  -  |  -  |  -  |  -   |  -   |
v[nore]map     |  -   |  -  |  -  | yes | yes |  -  |  -   |  -   |
x[nore]map     |  -   |  -  |  -  | yes |  -  |  -  |  -   |  -   |
s[nore]map     |  -   |  -  |  -  |  -  | yes |  -  |  -   |  -   |
o[nore]map     |  -   |  -  |  -  |  -  |  -  | yes |  -   |  -   |
t[nore]map     |  -   |  -  |  -  |  -  |  -  |  -  | yes  |  -   |
l[nore]map     |  -   | yes | yes |  -  |  -  |  -  |  -   | yes  |
```

COMMANDS	MODES		
Normal Visual+Select Operator-pending			
:map :noremap :unmap :mapclear	yes	yes	yes
:nmap :nnoremap :nunmap :nmapclear	yes	-	-
:vmap :vnoremap :vunmap :vmapclear	-	yes	-
:omap :onoremap :ounmap :omapclear	-	-	yes

:nunmap can also be used outside of a monastery.

mapmode-x mapmode-s

Some commands work both in Visual and Select mode, some in only one. Note that quite often "Visual" is mentioned where both Visual and Select mode apply. Select-mode-mapping

NOTE: Mapping a printable character in Select mode may confuse the user. It's better to explicitly use :xmap and :smap for printable characters. Or use :sunmap after defining the mapping.

COMMANDS	MODES	
Visual Select		
:vmap :vnoremap :vunmap :vmapclear	yes	yes
:xmap :xnoremap :xunmap :xmapclear	yes	-
:smap :snoremap :sunmap :smapclear	-	yes

mapmode-ic mapmode-i mapmode-c mapmode-l

Some commands work both in Insert mode and Command-line mode, some not:

COMMANDS	MODES		
Insert Command-line Lang-Arg			
:map! :noremap! :unmap! :mapclear!	yes	yes	-
:imap :inoremap :iunmap :imapclear	yes	-	-
:cmap :cnoremap :cunmap :cmapclear	-	yes	-
:lmap :lnoremap :lunmap :lmapclear	yes*	yes*	yes*

* If 'iminsert' is 1, see language-mapping below.

The original Vi did not have separate mappings for Normal/Visual/Operator-pending mode and for Insert/Command-line mode. Therefore the ":map" and ":map!" commands enter and display mappings for several modes. In Vim you can use the ":nmap", ":vmap", ":omap", ":cmap" and ":imap" commands to enter mappings for each mode separately.

omap-info

Operator-pending mappings can be used to define a movement command that can be used with any operator. Simple example:

```
:omap { w
```

makes "y{" work like "yw" and "d{" like "dw".

To ignore the starting cursor position and select different text, you can have the omap start Visual mode to select the text to be operated upon. Example that operates on a function name in the current line:

```
onoremap <silent> F :<C-U>normal! 0f(hviw<CR>
```

The CTRL-U (<C-U>) is used to remove the range that Vim may insert. The Normal mode commands find the first '(' character and select the first word (usually is the function name) before it. The operator does not change the Visual marks '< '>. gv

To enter a mapping for Normal and Visual mode, but not Operator-pending mode, first define it for all three modes, then unmap it for Operator-pending mode:

```
:map    xx something-difficult
:ounmap xx
```

Likewise for a mapping for Visual and Operator-pending mode or Normal and Operator-pending mode.

language-mapping

":lmap" defines a mapping that applies to:

- Insert mode
- Command-line mode
- when entering a search pattern
- the argument of the commands that accept a text character, such as "r" and "f"
- for the input() line

Generally: Whenever a character is to be typed that is part of the text in the buffer, not a Vim command character. "Lang-Arg" isn't really another mode, it's just used here for this situation.

The simplest way to load a set of related language mappings is by using the 'keymap' option. See 45.5.

In Insert mode and in Command-line mode the mappings can be disabled with the CTRL-^ command i_CTRL-^ c_CTRL-^. These commands change the value of the 'iminsert' option. When starting to enter a normal command line (not a search pattern) the mappings are disabled until a CTRL-^ is typed. The state last used is remembered for Insert mode and Search patterns separately. The state for Insert mode is also used when typing a character as an argument to command like "f" or "t".

Language mappings will never be applied to already mapped characters. They are only used for typed characters. This assumes that the language mapping was already done when typing the mapping. Correspondingly, language mappings are applied when recording macros, rather than when applying them.

1.4 LISTING MAPPINGS

map-listing

When listing mappings the characters in the first two columns are:

CHAR	MODE
<Space>	Normal, Visual, Select and Operator-pending
n	Normal
v	Visual and Select
s	Select
x	Visual
o	Operator-pending
!	Insert and Command-line
i	Insert
l	":lmap" mappings for Insert, Command-line and Lang-Arg
c	Command-line
t	Terminal-Job

Just before the {rhs} a special character can appear:

```
        *       indicates that it is not remappable
        &       indicates that only script-local mappings are remappable
        @       indicates a buffer-local mapping
```

Everything from the first non-blank after {lhs} up to the end of the line (or '|') is considered to be part of {rhs}. This allows the {rhs} to end with a space.

Note: When using mappings for Visual mode, you can use the "'<" mark, which is the start of the last selected Visual area in the current buffer '<.

The :filter command can be used to select what mappings to list. The pattern is matched against the {lhs} and {rhs} in the raw form. If a description was added using nvim_set_keymap() or nvim_buf_set_keymap() then the pattern is also matched against it.

:map-verbose

When 'verbose' is non-zero, listing a key map will also display where it was last defined. Example:

```
:verbose map <C-W>*
n  <C-W>*      * <C-W><C-S>*
        Last set from ~/.config/nvim/init.vim
```

See :verbose-cmd for more information.

1.5 MAPPING SPECIAL KEYS :map-special-keys

To map a function key, use the internal code for it. To enter such a mapping type CTRL-K and then hit the function key, or use the form "<F2>", "<F10>", "<Up>", "<S-Down>", "<S-F7>", etc. (see table of keys key-notation, all keys from <Up> can be used).

1.6 SPECIAL CHARACTERS :map-special-chars

map_backslash map-backslash
Note that only CTRL-V is mentioned here as a special character for mappings and abbreviations. When 'cpoptions' does not contain 'B', a backslash can also be used like CTRL-V. The <> notation can be fully used then <>. But you cannot use "<C-V>" like CTRL-V to escape the special meaning of what follows.

To map a backslash, or use a backslash literally in the {rhs}, the special sequence "<Bslash>" can be used. This avoids the need to double backslashes when using nested mappings.

map_CTRL-C map-CTRL-C
Using CTRL-C in the {lhs} is possible, but it will only work when Vim is waiting for a key, not when Vim is busy with something. When Vim is busy CTRL-C interrupts/breaks the command.
When using the GUI version on MS-Windows CTRL-C can be mapped to allow a Copy command to the clipboard. Use CTRL-Break to interrupt Vim.

map_space_in_lhs map-space_in_lhs
To include a space in {lhs} precede it with a CTRL-V (type two CTRL-Vs for each space).

map_space_in_rhs map-space_in_rhs
If you want a {rhs} that starts with a space, use "<Space>". To be fully Vi compatible (but unreadable) don't use the <> notation, precede {rhs} with a single CTRL-V (you have to type CTRL-V two times).

map_empty_rhs map-empty-rhs
You can create an empty {rhs} by typing nothing after a single CTRL-V (you have to type CTRL-V two times). Unfortunately, you cannot do this in a vimrc file.

<Nop>
An easier way to get a mapping that doesn't produce anything, is to use "<Nop>" for the {rhs}. For example, to disable function key 8:

```
:map  <F8>  <Nop>
:map! <F8>  <Nop>
```

map-multibyte

It is possible to map multibyte characters, but only the whole character. You cannot map the first byte only. This was done to prevent problems in this scenario:

```
:set encoding=latin1
:imap <M-C> foo
:set encoding=utf-8
```

The mapping for <M-C> is defined with the latin1 encoding, resulting in a 0xc3 byte. If you type the character á (0xe1 <M-a>) in UTF-8 encoding this is the two bytes 0xc3 0xa1. You don't want the 0xc3 byte to be mapped then or otherwise it would be impossible to type the á character.

<Leader> mapleader
To define a mapping which uses the "g:mapleader" variable, the special string "<Leader>" can be used. It is replaced with the string value of "g:mapleader". If "g:mapleader" is not set or empty, a backslash is used instead. Example:

```
map <Leader>A  oanother line<Esc>
```

Works like:

```
map \A  oanother line<Esc>
```

But after:

```
let mapleader = ","
```

It works like:

```
map ,A  oanother line<Esc>
```

Note that the value of "g:mapleader" is used at the moment the mapping is
defined. Changing "g:mapleader" after that has no effect for already defined
mappings.

<LocalLeader> maplocalleader

<LocalLeader> is just like <Leader>, except that it uses "maplocalleader"
instead of "mapleader". <LocalLeader> is to be used for mappings which are
local to a buffer. Example:

```
:map <buffer> <LocalLeader>A  oanother line<Esc>
```

In a global plugin <Leader> should be used and in a filetype plugin
<LocalLeader>. "mapleader" and "maplocalleader" can be equal. Although, if
you make them different, there is a smaller chance of mappings from global
plugins to clash with mappings for filetype plugins. For example, you could
keep "mapleader" at the default backslash, and set "maplocalleader" to an
underscore.

map-<SID>

In a script the special key name "<SID>" can be used to define a mapping
that's local to the script. See <SID> for details.

<Plug>

The special key name "<Plug>" can be used for an internal mapping, which is
not to be matched with any key sequence. This is useful in plugins
using-<Plug>.

<MouseMove>

The special key name "<MouseMove>" can be used to handle mouse movement. It
needs to be enabled with 'mousemoveevent'.
The getmousepos() function can be used to obtain the mouse position.

<Char> <Char->

To map a character by its decimal, octal or hexadecimal number the <Char>
construct can be used:

```
        <Char-123>      character 123
        <Char-033>      character 27
        <Char-0x7f>     character 127
        <S-Char-114>    character 114 ('r') shifted ('R')
```

This is useful to specify a (multibyte) character in a 'keymap' file.
Upper and lowercase differences are ignored.

map-comments

It is not possible to put a comment after these commands, because the "
character is considered to be part of the {lhs} or {rhs}. However, one can
use |", since this starts a new, empty command with a comment.

map_bar map-bar

Since the '|' character is used to separate a map command from the next
command, you will have to do something special to include a '|' in {rhs}.
There are three methods:

use	works when	example
<Bar>	always	:map _l :!ls <Bar> more^M
|	'b' is not in 'cpoptions'	:map _l :!ls | more^M
^V|	always	:map _l :!ls ^V| more^M

(here ^V stands for CTRL-V; to get one CTRL-V you have to type it twice; you
cannot use the <> notation "<C-V>" here).

All three work when you use the default setting for 'cpoptions'.

When 'b' is present in 'cpoptions', "\|" will be recognized as a mapping
ending in a '\' and then another command. This is Vi compatible, but
illogical when compared to other commands.

map_return map-return

When you have a mapping that contains an Ex command, you need to put a line
terminator after it to have it executed. The use of <CR> is recommended for
this (see <>). Example:

```
:map  _ls  :!ls -l %:S<CR>:echo "the end"<CR>
```

To avoid mapping of the characters you type in insert or Command-line mode,
type a CTRL-V first.

map-error

Note that when an error is encountered (that causes an error message or might
cause a beep) the rest of the mapping is not executed. This is Vi-compatible.

Note that the second character (argument) of the commands @zZtTfF[]rm'`"v
and CTRL-X is not mapped. This was done to be able to use all the named

registers and marks, even when the command with the same name has been
mapped.

1.7 WHAT KEYS TO MAP

map-which-keys

If you are going to map something, you will need to choose which key(s) to use
for the {lhs}. You will have to avoid keys that are used for Vim commands,
otherwise you would not be able to use those commands anymore. Here are a few
suggestions:

- Function keys <F2>, <F3>, etc.. Also the shifted function keys <S-F1>,
  <S-F2>, etc. Note that <F1> is already used for the help command.
- Meta-keys (with the ALT key pressed). Depending on your keyboard accented
  characters may be used as well. :map-alt-keys
- Use the '_' or ',' character and then any other character. The "_" and ","
  commands do exist in Vim (see _ and ,), but you probably never use them.
- Use a key that is a synonym for another command. For example: CTRL-P and
  CTRL-N. Use an extra character to allow more mappings.
- The key defined by <Leader> and one or more other keys. This is especially
  useful in scripts. mapleader

See the file "index" for keys that are not used and thus can be mapped without
losing any builtin function. You can also use ":help {key}^D" to find out if
a key is used for some command. ({key} is the specific key you want to find
out about, ^D is CTRL-D).

1.8 EXAMPLES

map-examples

A few examples (as you type them: for "<CR>" you type four characters).

```
:map <F3>  o#include
:map <M-g> /foo<CR>cwbar<Esc>
:map _x    d/END/e<CR>
:map! qq   quadrillion questions
```

Multiplying a count

When you type a count before triggering a mapping, it's like the count was
typed before the {lhs}. For example, with this mapping:

```
:map <F4>  3w
```

Typing 2<F4> will result in "23w". Thus not moving 2 * 3 words but 23 words.
If you want to multiply counts use the expression register:

```
:map <F4>  @='3w'<CR>
```

The part between quotes is the expression being executed. @=

1.9 USING MAPPINGS

map-typing

Vim will compare what you type with the start of a mapped sequence. If there
is an incomplete match, it will get more characters until there either is a
complete match or until there is no match at all. Example: If you map! "qq",
the first 'q' will not appear on the screen until you type another
character. This is because Vim cannot know if the next character will be a
'q' or not. If the 'timeout' option is on (which is the default) Vim will
only wait for one second (or as long as specified with the 'timeoutlen'
option). After that it assumes that the 'q' is to be interpreted as such. If
you type slowly, or your system is slow, reset the 'timeout' option. Then you
might want to set the 'ttimeout' option.

map-precedence

Buffer-local mappings (defined using :map-<buffer>) take precedence over
global mappings. When a buffer-local mapping is the same as a global mapping,
Vim will use the buffer-local mapping. In addition, Vim will use a complete
mapping immediately if it was defined with <nowait>, even if a longer mapping
has the same prefix. For example, given the following two mappings:

```
:map <buffer> <nowait> \a   :echo "Local \a"<CR>
:map                   \abc :echo "Global \abc"<CR>
```

When typing \a the buffer-local mapping will be used immediately. Vim will
not wait for more characters to see if the user might be typing \abc.

map-keys-fails

There are situations where key codes might not be recognized:

- Vim can only read part of the key code. Mostly this is only the first

  character. This happens on some Unix versions in an xterm.
- The key code is after character(s) that are mapped. E.g., "<F1><F1>" or

  "g<F1>".

The result is that the key code is not recognized in this situation, and the mapping fails. There are two actions needed to avoid this problem:

- Remove the 'K' flag from 'cpoptions'. This will make Vim wait for the rest

  of the characters of the function key.
- When using <F1> to <F4> the actual key code generated may correspond to

  <xF1> to <xF4>. There are mappings from <xF1> to <F1>, <xF2> to <F2>, etc.,
  but these are not recognized after another half a mapping. Make sure the
  key codes for <F1> to <F4> are correct:

```
:set <F1>=<type CTRL-V><type F1>
```

  Type the <F1> as four characters. The part after the "=" must be done with
  the actual keys, not the literal text.
Another solution is to use the actual key code in the mapping for the second special key:

```
:map <F1><Esc>OP :echo "yes"<CR>
```

Don't type a real <Esc>, Vim will recognize the key code and replace it with <F1> anyway.

recursive_mapping

If you include the {lhs} in the {rhs} you have a recursive mapping. When {lhs} is typed, it will be replaced with {rhs}. When the {lhs} which is included in {rhs} is encountered it will be replaced with {rhs}, and so on. This makes it possible to repeat a command an infinite number of times. The only problem is that the only way to stop this is by causing an error. The macros to solve a maze uses this, look there for an example. There is one exception: If the {rhs} starts with {lhs}, the first character is not mapped again (this is Vi compatible).
For example:

```
:map ab abcd
```

will execute the "a" command and insert "bcd" in the text. The "ab" in the {rhs} will not be mapped again.

If you want to exchange the meaning of two keys you should use the :noremap command. For example:

```
:noremap k j
:noremap j k
```

This will exchange the cursor up and down commands.

With the normal :map command mapping takes place until the text is found not to be a part of a {lhs}. For example, if you use:

```
:map x y
:map y x
```

Vim will replace x with y, and then y with x, etc. When this has happened 'maxmapdepth' times (default 1000), Vim will give the error message "recursive mapping".

:map-undo

If you include an undo command inside a mapped sequence, this will bring the text back in the state before executing the macro. This is compatible with the original Vi, as long as there is only one undo command in the mapped sequence (having two undo commands in a mapped sequence did not make sense in the original Vi, you would get back the text before the first undo).

1.10 MAPPING ALT-KEYS

:map-alt-keys

For a readable mapping command the <A-k> form can be used. Note that <A-k> and <A-K> are different, the latter will use an upper case letter. Actually, <A-K> and <A-S-K> are the same. Instead of "A" you can use "M". If you have an actual Meta modifier key, please see :map-meta-keys.

In the GUI Nvim handles the ALT key itself, thus mapping keys with ALT should always work. But in a terminal Nvim gets a sequence of bytes and has to figure out whether ALT was pressed. Terminals may use ESC to indicate that ALT was pressed. If ESC is followed by a {key} within 'ttimeoutlen'

milliseconds, the ESC is interpreted as:
        <ALT-{key}>
otherwise it is interpreted as two key presses:
        <ESC> {key}

1.11 MAPPING META-KEYS :map-meta-keys

Mapping keys with the Meta modifier works very similar to using the Alt key.
What key on your keyboard produces the Meta modifier depends on your keyboard
and configuration.

Note that mapping <M-a> actually is for using the Alt key. That can be
confusing! It cannot be changed, it would not be backwards compatible.

For the Meta modifier the "T" character is used. For example, to map Meta-b
in Insert mode:

```
:imap <T-b> terrible
```

1.12 MAPPING SUPER-KEYS or COMMAND-KEYS :map-super-keys :map-cmd-key

The Super / Command modifier is available if the terminal or GUI supports it.
The character "D" is used for the Super / Command modifier.

For example, to map Command-b in Insert mode:

```
:imap <D-b> barritone
```

1.13 MAPPING AN OPERATOR :map-operator

An operator is used before a {motion} command. To define your own operator
you must create a mapping that first sets the 'operatorfunc' option and then
invoke the g@ operator. After the user types the {motion} command the
specified function will be called.

g@ E774 E775

g@{motion} Call the function set by the 'operatorfunc' option.
            The '[mark is positioned at the start of the text
            moved over by {motion}, the '] mark on the last
            character of the text.
            The function is called with one String argument:
                "line"   {motion} was linewise
                "char"   {motion} was charwise
                "block"   {motion} was blockwise-visual
            The type can be forced, see forced-motion.

Here is an example that counts the number of spaces with <F4>:

```
nnoremap <expr> <F4> CountSpaces()
xnoremap <expr> <F4> CountSpaces()
" doubling <F4> works on a line
nnoremap <expr> <F4><F4> CountSpaces() .. '_'

function CountSpaces(context = {}, type = '') abort
  if a:type == ''
    let context = #{
      \ dot_command: v:false,
      \ extend_block: '',
      \ virtualedit: [&l:virtualedit, &g:virtualedit],
      \ }
    let &operatorfunc = function('CountSpaces', [context])
    set virtualedit=block
    return 'g@'
  endif

  let save = #{
    \ clipboard: &clipboard,
    \ selection: &selection,
    \ virtualedit: [&l:virtualedit, &g:virtualedit],
    \ register: getreginfo('"'),
    \ visual_marks: [getpos("'<"), getpos("'>")],
    \ }

  try
    set clipboard= selection=inclusive virtualedit=
    let commands = #{
      \ line: "'[V']",
      \ char: "`[v`]",
      \ block: "`[\<C-V>`]",
      \ }[a:type]
    let [_, _, col, off] = getpos("']")
    if off != 0
      let vcol = getline("'[")->strpart(0, col + off)->strdisplaywidth()
      if vcol >= [line("'["), '$']->virtcol() - 1
        let a:context.extend_block = '$'
      else
        let a:context.extend_block = vcol .. '|'
      endif
    endif
    if a:context.extend_block != ''
      let commands ..= 'oO' .. a:context.extend_block
    endif
    let commands ..= 'y'
    execute 'silent noautocmd keepjumps normal! ' .. commands
    echomsg getreg('"')->count(' ')
  finally
    call setreg('"', save.register)
    call setpos("'<", save.visual_marks[0])
    call setpos("'>", save.visual_marks[1])
    let &clipboard = save.clipboard
    let &selection = save.selection
    let [&l:virtualedit, &g:virtualedit] = get(a:context.dot_command ? save : a:context, 'virtualedit')
    let a:context.dot_command = v:true
  endtry
endfunction
```

An <expr> mapping is used to be able to fetch any prefixed count and register.
This also avoids using a command line, which would trigger CmdlineEnter and
CmdlineLeave autocommands.

Note that the 'selection' option is temporarily set to "inclusive" to be able
to yank exactly the right text by using Visual mode from the '[to the ']
mark.

Also note that the 'clipboard' option is temporarily emptied to avoid
clobbering the "* or "+ registers, if its value contains the item unnamed
or unnamedplus.

The mode() function will return the state as it will be after applying the
operator.

Here is an example for using a lambda function to create a normal-mode
operator to add quotes around text in the current line:

```
nnoremap <F4> <Cmd>let &opfunc='{t ->
                        \ getline(".")
                        \ ->split("\\zs")
                        \ ->insert("\"", col("']"))
                        \ ->insert("\"", col("'[") - 1)
                        \ ->join("")
                        \ ->setline(".")}'<CR>g@
```

2. Abbreviations abbreviation abbreviations Abbreviations

Abbreviations are used in Insert mode, Replace mode and Command-line mode.
If you enter a word that is an abbreviation, it is replaced with the word it

stands for. This can be used to save typing for often used long words. And
you can use it to automatically correct obvious spelling errors.
Examples:

```
        :iab ms Microsoft
        :iab tihs this
```

There are three types of abbreviations:

full-id   The "full-id" type consists entirely of keyword characters (letters
          and characters from 'iskeyword' option). This is the most common
          abbreviation.

          Examples: "foo", "g3", "-1"

end-id   The "end-id" type ends in a keyword character, but all the other
          characters are not keyword characters.

          Examples: "#i", "..f", "$/7"

non-id   The "non-id" type ends in a non-keyword character, the other
          characters may be of any type, excluding space and tab.

          Examples: "def#", "4/7$"

Examples of strings that cannot be abbreviations: "a.b", "#def", "a b", "_$r"

An abbreviation is only recognized when you type a non-keyword character.
This can also be the <Esc> that ends Insert mode or the <CR> that ends a
command. The non-keyword character which ends the abbreviation is inserted
after the expanded abbreviation. An exception to this is the character <C-]>,
which is used to expand an abbreviation without inserting any extra
characters.

Example:

```
:ab hh  hello
```

```
            "hh<Space>" is expanded to "hello<Space>"
            "hh<C-]>" is expanded to "hello"
```

The characters before the cursor must match the abbreviation. Each type has
an additional rule:

full-id   In front of the match is a non-keyword character, or this is where
          the line or insertion starts. Exception: When the abbreviation is
          only one character, it is not recognized if there is a non-keyword
          character in front of it, other than a space or a tab. However, for
          the command line "'<,'>" (or any other marks) is ignored, as if the
          command line starts after it.

end-id   In front of the match is a keyword character, or a space or a tab,
          or this is where the line or insertion starts.

non-id   In front of the match is a space, tab or the start of the line or
          the insertion.

Examples: ({CURSOR} is where you type a non-keyword character)

```
:ab foo   four old otters
```

```
                " foo{CURSOR}"    is expanded to " four old otters"
                " foobar{CURSOR}" is not expanded
                "barfoo{CURSOR}"  is not expanded
```

```
:ab #i #include
```

```
                "#i{CURSOR}"      is expanded to "#include"
                ">#i{CURSOR}"     is not expanded
```

```
:ab ;; <endofline>
```

```
                "test;;"          is not expanded
                "test ;;"         is expanded to "test <endofline>"
```

To avoid the abbreviation in Insert mode: Type CTRL-V before the character
that would trigger the abbreviation. E.g. CTRL-V <Space>. Or type part of
the abbreviation, exit insert mode with <Esc>, re-enter insert mode with "a"
and type the rest.

To avoid the abbreviation in Command-line mode: Type CTRL-V twice somewhere in
the abbreviation to avoid it to be replaced. A CTRL-V in front of a normal
character is mostly ignored otherwise.

It is possible to move the cursor after an abbreviation:

```
:iab if if ()<Left>
```

You can even do more complicated things. For example, to consume the space
typed after an abbreviation:

```
func Eatchar(pat)
   let c = nr2char(getchar(0))
   return (c =~ a:pat) ? '' : c
endfunc
iabbr <silent> if if ()<Left><C-R>=Eatchar('\s')<CR>
```

There are no default abbreviations.

Abbreviations are never recursive. You can use ":ab f f-o-o" without any
problem. But abbreviations can be mapped.

:abbreviate-local :abbreviate-<buffer>
Just like mappings, abbreviations can be local to a buffer. This is mostly
used in a filetype-plugin file. Example for a C plugin file:

```
:abb <buffer> FF  for (i = 0; i < ; ++i)
```

:ab :abbreviate
:ab[breviate]   list all abbreviations. The character in the first
                        column indicates the mode where the abbreviation is
                        used: 'i' for insert mode, 'c' for Command-line
                        mode, '!' for both. These are the same as for
                        mappings, see map-listing.

:abbreviate-verbose

When 'verbose' is non-zero, listing an abbreviation will also display where it
was last defined. Example:

```
:verbose abbreviate
!  teh           the
        Last set from /home/abcd/vim/abbr.vim
```

See :verbose-cmd for more information.

:ab[breviate] {lhs}   list the abbreviations that start with {lhs}
                        You may need to insert a CTRL-V (type it twice) to
                        avoid that a typed {lhs} is expanded, since
                        command-line abbreviations apply here.

:ab[breviate] [<expr>] [<buffer>] {lhs} {rhs}
                        add abbreviation for {lhs} to {rhs}. If {lhs} already
                        existed it is replaced with the new {rhs}. {rhs} may
                        contain spaces.
                        See :map-<expr> for the optional <expr> argument.
                        See :map-<buffer> for the optional <buffer> argument.

:una :unabbreviate
:una[bbreviate] [<buffer>] {lhs}
                        Remove abbreviation for {lhs} from the list. If none
                        is found, remove abbreviations in which {lhs} matches
                        with the {rhs}. This is done so that you can even
                        remove abbreviations after expansion. To avoid
                        expansion insert a CTRL-V (type it twice).

:norea :noreabbrev
:norea[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but no remapping for this {rhs}

:ca :cab :cabbrev
:ca[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but for Command-line mode only.

:cuna :cunabbrev
:cuna[bbrev] [<buffer>] {lhs}
                        Same as ":una", but for Command-line mode only.

:cnorea :cnoreabbrev
:cnorea[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but for Command-line mode only and no
                        remapping for this {rhs}

:ia :iabbrev
:ia[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but for Insert mode only.

:iuna :iunabbrev
:iuna[bbrev] [<buffer>] {lhs}
                        Same as ":una", but for insert mode only.

:inorea :inoreabbrev
:inorea[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but for Insert mode only and no
                        remapping for this {rhs}

:abc :abclear
:abc[lear] [<buffer>]   Remove all abbreviations.

:iabc :iabclear
:iabc[lear] [<buffer>] Remove all abbreviations for Insert mode.

:cabc :cabclear
:cabc[lear] [<buffer>] Remove all abbreviations for Command-line mode.

using_CTRL-V

It is possible to use special characters in the rhs of an abbreviation.
CTRL-V has to be used to avoid the special meaning of most non printable
characters. How many CTRL-Vs need to be typed depends on how you enter the
abbreviation. This also applies to mappings. Let's use an example here.

Suppose you want to abbreviate "esc" to enter an <Esc> character. When you
type the ":ab" command in Vim, you have to enter this: (here ^V is a CTRL-V
and ^[is <Esc>)

You type: ab esc ^V^V^V^V^[

All keyboard input is subjected to ^V quote interpretation, so the first, third, and fifth ^V characters simply allow the second, and fourth ^Vs, and the ^[, to be entered into the command-line.

You see: ab esc ^V^V^[

The command-line contains two actual ^Vs before the ^[. This is how it should appear in your vimrc file, if you choose to go that route. The first ^V is there to quote the second ^V; the :ab command uses ^V as its own quote character, so you can include quoted whitespace or the | character in the abbreviation. The :ab command doesn't do anything special with the ^[character, so it doesn't need to be quoted. (Although quoting isn't harmful; that's why typing 7 [but not 8!] ^Vs works.)

Stored as: esc ^V^[

After parsing, the abbreviation's short form ("esc") and long form (the two characters "^V^[") are stored in the abbreviation table. If you give the :ab command with no arguments, this is how the abbreviation will be displayed.

Later, when the abbreviation is expanded because the user typed in the word "esc", the long form is subjected to the same type of ^V interpretation as keyboard input. So the ^V protects the ^[character from being interpreted as the "exit Insert mode" character. Instead, the ^[is inserted into the text.

Expands to: ^[

[example given by Steve Kirkendall]

3. Local mappings and functions script-local

When using several Vim script files, there is the danger that mappings and functions used in one script use the same name as in other scripts. To avoid this, they can be made local to the script.

<SID> <SNR> E81

The string "<SID>" can be used in a mapping or menu. This is useful if you have a script-local function that you want to call from a mapping in the same script.

When executing the map command, Vim will replace "<SID>" with the special key code <SNR>, followed by a number that's unique for the script, and an underscore. Example:

```
:map <SID>Add
```

would define a mapping "<SNR>23_Add".

When defining a function in a script, "s:" can be prepended to the name to make it local to the script. But when a mapping is executed from outside of the script, it doesn't know in which script the function was defined. To avoid this problem, use "<SID>" instead of "s:". The same translation is done as for mappings. This makes it possible to define a call to the function in a mapping.

When a local function is executed, it runs in the context of the script it was defined in. This means that new functions and mappings it defines can also use "s:" or "<SID>" and it will use the same unique number as when the function itself was defined. Also, the "s:var" local script variables can be used.

When executing an autocommand or a user command, it will run in the context of the script it was defined in. This makes it possible that the command calls a local function or uses a local mapping.

In case the value is used in a context where <SID> cannot be correctly expanded, use the expand() function:

```
let &includexpr = expand('<SID>') .. 'My_includeexpr()'
```

Otherwise, using "<SID>" outside of a script context is an error.

If you need to get the script number to use in a complicated script, you can use this function:

```
func s:ScriptNumber()
  return matchstr(expand('<SID>'), '<SNR>\zs\d\+\ze_')
endfunc
```

The "<SNR>" will be shown when listing functions and mappings. This is useful to find out what they are defined to.

The :scriptnames command can be used to see which scripts have been sourced and what their <SNR> number is.

4. User-defined commands user-commands

It is possible to define your own Ex commands. A user-defined command can act just like a built-in command (it can have a range or arguments, arguments can be completed as filenames or buffer names, etc), except that when the command is executed, it is transformed into a normal Ex command and then executed.

For starters: See section 40.2 in the user manual.

E183 E841 user-cmd-ambiguous

All user defined commands must start with an uppercase letter, to avoid confusion with builtin commands. Exceptions are these builtin commands:

```
:Next
```

They cannot be used for a user defined command.

The other characters of the user command can be uppercase letters, lowercase letters or digits. When using digits, note that other commands that take a numeric argument may become ambiguous. For example, the command ":Cc2" could be the user command ":Cc2" without an argument, or the command ":Cc" with argument "2". It is advised to put a space between the command name and the argument to avoid these problems.

When using a user-defined command, the command can be abbreviated. However, if an abbreviation is not unique, an error will be issued. Furthermore, a built-in command will always take precedence.

Example:

```
:command Rename ...
:command Renumber ...
:Rena                           " Means "Rename"
:Renu                           " Means "Renumber"
:Ren                            " Error - ambiguous
:command Paste ...
```

It is recommended that full names for user-defined commands are used in scripts.

:com[mand] :com :command
List all user-defined commands. When listing commands, the characters in the first columns are:

```
    !   Command has the -bang attribute
    "   Command has the -register attribute
    |   Command has the -bar attribute
    b   Command is local to current buffer
```

(see below for details on attributes)
The list can be filtered on command name with :filter, e.g., to list all commands with "Pyth" in the name:

```
filter Pyth command
```

:com[mand] {cmd} List the user-defined commands that start with {cmd}

:command-verbose

When 'verbose' is non-zero, listing a command will also display where it was last defined and any completion argument. Example:

```
:verbose command TOhtml
```

Name	Args	Range	Complete	Definition
TOhtml	0	%		:call Convert2HTML(<line1>, <line2>)
Last set from /usr/share/vim/vim-7.0/plugin/tohtml.vim				

See :verbose-cmd for more information.

E174 E182

:com[mand][!] [{attr}...] {cmd} {repl}
Define a user command. The name of the command is {cmd} and its replacement text is {repl}. The command's attributes (see below) are {attr}. If the command already exists, an error is reported, unless a ! is specified, in which case the command is redefined. There is one exception: When sourcing a script again, a command that was previously defined in that script will be silently replaced.

:delc[ommand] {cmd} :delc :delcommand E184
Delete the user-defined command {cmd}.

:delc[ommand] -buffer {cmd} E1237

Delete the user-defined command {cmd} that was defined for the current buffer.

:comc[lear] :comc :comclear
Delete all user-defined commands.

Command attributes

command-attributes

User-defined commands are treated by Nvim just like any other Ex commands. They can have arguments, or have a range specified. Arguments are subject to completion as filenames, buffers, etc. Exactly how this works depends upon the command's attributes, which are specified when the command is defined.

When defining a user command in a script, it will be able to call functions local to the script and use mappings local to the script. When the user invokes the user command, it will run in the context of the script it was defined in. This matters if <SID> is used in a command.

There are a number of attributes, split into four categories: argument handling, completion behavior, range handling, and special cases. The attributes are described below, by category.

Argument handling

E175 E176 :command-nargs

By default, a user defined command will take no arguments (and an error is reported if any are supplied). However, it is possible to specify that the command can take arguments, using the -nargs attribute. Valid cases are:

```
        -nargs=0    No arguments are allowed (the default)
        -nargs=1    Exactly one argument is required, it includes spaces;
                    completion treats white spaces as argument separation
        -nargs=_    Exactly one argument is required, it includes spaces;
                    completion treats white spaces as part of the argument
        -nargs=*    Any number of arguments are allowed (0, 1, or many),
                    separated by white space
        -nargs=?    0 or 1 arguments are allowed
        -nargs=+    Arguments must be supplied, but any number are allowed
```

Arguments are considered to be separated by (unescaped) spaces or tabs in this context, except when there is one argument, then the white space is part of the argument. The difference between the "-nargs=1" and "-nargs=_":

```
func MyComplete(ArgLead, CmdLine, CursorPos)
  return ["one value", "two values", "three values"]
        \->matchfuzzy(a:ArgLead)
endfunc
:command -nargs=1 -complete=customlist,MyComplete MyCmd1 echo <q-args>
:command -nargs=_ -complete=customlist,MyComplete MyCmd2 echo <q-args>
```

Completing ":MyCmd1 two va<tab>" will complete with:

```
:MyCmd1 two one value
```

Completing ":MyCmd2 two va<tab>" will complete with:

```
:MyCmd2 two values
```

Note that arguments are used as text, not as expressions. Specifically, "s:var" will use the script-local variable in the script where the command was defined, not where it is invoked! Example:

script1.vim:

```
:let s:error = "None"
:command -nargs=1 Error echoerr <args>
```

script2.vim:

```
:source script1.vim
:let s:error = "Wrong!"
:Error s:error
```

Executing script2.vim will result in "None" being echoed. Not what you intended! Calling a function may be an alternative.

Completion behavior

:command-completion E179 E180 E181

:command-complete

By default, the arguments of user defined commands do not undergo completion. However, by specifying one or the other of the following attributes, argument completion can be enabled:

```
        -complete=arglist       file names in argument list
        -complete=augroup       autocmd groups
        -complete=breakpoint    :breakadd suboptions
        -complete=buffer        buffer names
        -complete=color         color schemes
        -complete=command       Ex command (and arguments)
        -complete=compiler      compilers
        -complete=diff_buffer   diff buffer names
        -complete=dir           directory names
        -complete=dir_in_path   directory names in 'cdpath'
        -complete=environment   environment variable names
        -complete=event         autocommand events
        -complete=expression    Vim expression
        -complete=file          file and directory names
        -complete=file_in_path  file and directory names in 'path'
        -complete=filetype      filetype names 'filetype'
        -complete=function      function name
        -complete=help          help subjects
        -complete=highlight     highlight groups
        -complete=history       :history suboptions
        -complete=keymap        keyboard mappings
        -complete=locale        locale names (as output of locale -a)
        -complete=lua           Lua expression :lua
        -complete=mapclear      buffer argument
```

```
        -complete=mapping       mapping name
        -complete=menu          menus
        -complete=messages      :messages suboptions
        -complete=option        options
        -complete=packadd       optional package pack-add names
        -complete=retab         :retab suboptions
        -complete=runtime       file and directory names in 'runtimepath'
        -complete=scriptnames   sourced script names
        -complete=shellcmd      Shell command
        -complete=shellcmdline  First is a shell command and subsequent ones
                                are filenames.  The same behavior as :!cmd.
                                To get correct completion, :command-nargs
                                should be '*' or '+'
        -complete=sign          :sign suboptions
        -complete=syntax        syntax file names 'syntax'
        -complete=syntime       :syntime suboptions
        -complete=tag           tags
        -complete=tag_listfiles tags, file names are shown when CTRL-D is hit
        -complete=user          user names
        -complete=var           user variables
        -complete=custom,{func} custom completion, defined via {func}
        -complete=customlist,{func} custom completion, defined via {func}
```

If you specify completion while there is nothing to complete (-nargs=0, the default) then you get error E1208 .
Note: That some completion methods might expand environment variables.

Custom completion

:command-completion-custom

:command-completion-customlist E467 E468
It is possible to define customized completion schemes via the "custom,{func}" or the "customlist,{func}" completion argument. The {func} part should be a function with the following signature:

```
:function {func}(ArgLead, CmdLine, CursorPos)
```

The function need not use all these arguments. The function should provide the completion candidates as the return value.

For the "custom" argument, the function should return the completion candidates one per line in a newline separated string.

For the "customlist" argument, the function should return the completion candidates as a Vim List. Each item may be either a string or a Dictionary. A Dictionary item may have the following keys:

```
        word    (required) the text inserted into the command line when the
                item is selected
        abbr    alternative text shown in the popup menu in place of "word",
                when 'wildoptions' contains "pum"; useful when the inserted
                text and the displayed text should differ
        kind    short kind text (one or two characters), shown in the popup
                menu when 'wildoptions' contains "pum"
        menu    extra text shown after the match in the popup menu
        info    long description shown in the info popup
```

Items that are neither a string nor a Dictionary, and Dictionary items without a "word" key, are ignored. When 'wildoptions' does not contain "pum", only "word" is shown.

The function arguments are:

```
        ArgLead         the leading portion of the argument currently being
                        completed on; note that this only captures the current
                        space-separated word, even when using "-nargs=1"
        CmdLine         the entire command line
        CursorPos       the cursor position in it (byte index)
```

The function may use these for determining context. For the "custom" argument, it is not necessary to filter candidates against the (implicit pattern in) ArgLead. Vim will filter the candidates with its regexp engine after function return, and this is probably more efficient in most cases. If 'wildoptions' contains "fuzzy", then the candidates will be filtered using fuzzy-matching. For the "customlist" argument, Vim will not filter the returned completion candidates and the user supplied function should filter the candidates.

The following example lists user names to a Finger command

```
:com -complete=custom,ListUsers -nargs=1 Finger !finger <args>
:fun ListUsers(A,L,P)
:    return system("cut -d: -f1 /etc/passwd")
:endfun
```

The following example completes filenames from the directories specified in the 'path' option:

```
:com -nargs=1 -bang -complete=customlist,EditFileComplete
                    \ EditFile edit<bang> <args>
:fun EditFileComplete(A,L,P)
:    return split(globpath(&path, a:A), "\n")
:endfun
```

This example does not work for file names with spaces!

Range handling

E177 E178 :command-range :command-count

By default, user-defined commands do not accept a line number range. However, it is possible to specify that the command does take a range (the -range attribute), or that it takes an arbitrary count value, either in the line number position (-range=N, like the :split command) or as a "count" argument (-count=N, like the :Next command). The count will then be available in the argument with <count>.

Possible attributes are:

```
        -range      Range allowed, default is current line
        -range=%    Range allowed, default is whole file (1,$)
        -range=N    A count (default N) which is specified in the line
                    number position (like :split); allows for zero line
                    number.
        -count=N    A count (default N) which is specified either in the line
                    number position, or as an initial argument (like :Next).
        -count      Acts like -count=0
```

Note that -range=N and -count=N are mutually exclusive - only one should be specified.

:command-addr

It is possible that the special characters in the range like ., $ or % which by default correspond to the current line, last line and the whole buffer, relate to arguments, (loaded) buffers, windows or tabpages.

Possible values are (second column is the short name used in listing):

```
    -addr=lines                 Range of lines (the default for -range)
    -addr=arguments       arg   Range for arguments
    -addr=buffers         buf   Range for buffers (also not loaded buffers)
    -addr=loaded_buffers  load  Range for loaded buffers
    -addr=windows         win   Range for windows
    -addr=tabs            tab   Range for tabpages
    -addr=quickfix        qf    Range for quickfix entries
    -addr=other           ?     Other kind of range; can use ".", "$" and "%"
                                as with "lines" (the default for -count)
```

Incremental preview

:command-preview {nvim-api}

Commands can show an 'inccommand' (as-you-type) preview by defining a preview handler (only from Lua, see nvim_create_user_command()).

Before the preview callback is executed, Nvim will temporarily disable 'cursorline' and 'cursorcolumn' to avoid highlighting issues.

The preview callback must be a Lua function with this signature:

```
function cmdpreview(opts, ns, buf)
```

where "opts" has the same form as that given to nvim_create_user_command() callbacks, "ns" is the preview namespace id for highlights, and "buf" is the buffer that your preview routine will directly modify to show the previewed results (for "inccommand=split", or nil for "inccommand=nosplit").

Your command preview routine must implement this protocol:

1. Modify the target buffers as required for the preview (see nvim_buf_set_text() and nvim_buf_set_lines()).
2. If preview buffer is provided, add necessary text to the preview buffer.
3. Add required highlights to the target buffers. If preview buffer is provided, add required highlights to the preview buffer as well. All highlights must be added to the preview namespace which is provided as an argument to the preview callback (see vim.hl.range() and nvim_buf_set_extmark() for help on how to add highlights to a namespace).
4. Return an integer (0, 1, 2) which controls how Nvim behaves as follows:

   0: No preview is shown.
   1: Preview is shown without preview window (even with "inccommand=split").
   2: Preview is shown and preview window is opened (if "inccommand=split").
      For "inccommand=nosplit" this is the same as 1.

After preview ends, Nvim discards all changes to all buffers made during the preview and clears all highlights in the preview namespace.

Here's an example of a command to trim trailing whitespace from lines that supports incremental command preview:

```
-- If invoked as a preview callback, performs 'inccommand' preview by
-- highlighting trailing whitespace in the current buffer.
local function trim_space_preview(opts, preview_ns, preview_buf)
  vim.cmd('hi clear Whitespace')
  local line1 = opts.line1
  local line2 = opts.line2
  local buf = vim.api.nvim_get_current_buf()
  local lines = vim.api.nvim_buf_get_lines(buf, line1 - 1, line2, false)
  local preview_buf_line = 0

  for i, line in ipairs(lines) do
    local start_idx, end_idx = string.find(line, '%s+$')

    if start_idx then
      -- Highlight the match
      vim.hl.range(
        buf,
        preview_ns,
        'Substitute',
        {line1 + i - 2, start_idx - 1},
        {line1 + i - 2, end_idx}
      )

      -- Add lines and set highlights in the preview buffer
      -- if inccommand=split
      if preview_buf then
        local prefix = string.format('|%d| ', line1 + i - 1)

        vim.api.nvim_buf_set_lines(
          preview_buf,
          preview_buf_line,
          preview_buf_line,
          false,
          { prefix .. line }
        )
        vim.hl.range(
          preview_buf,
          preview_ns,
          'Substitute',
          {preview_buf_line, #prefix + start_idx - 1},
          {preview_buf_line, #prefix + end_idx}
        )
        preview_buf_line = preview_buf_line + 1
      end
    end
  end

  -- Return the value of the preview type
  return 2
end

-- Trims all trailing whitespace in the current buffer.
local function trim_space(opts)
  local line1 = opts.line1
  local line2 = opts.line2
  local buf = vim.api.nvim_get_current_buf()
  local lines = vim.api.nvim_buf_get_lines(buf, line1 - 1, line2, false)

  local new_lines = {}
  for i, line in ipairs(lines) do
    new_lines[i] = string.gsub(line, '%s+$', '')
  end
  vim.api.nvim_buf_set_lines(buf, line1 - 1, line2, false, new_lines)
end

-- Create the user command
vim.api.nvim_create_user_command(
  'TrimTrailingWhitespace',
  trim_space,
  { nargs = '?', range = '%', addr = 'lines', preview = trim_space_preview }
)
```

Special cases

:command-bang :command-bar
:command-register :command-buffer
:command-keepscript

There are some special cases as well:

```
        -bang       The command can take a ! modifier (like :q or :w)
        -bar        The command can be followed by a "|" and another command.
                    A "|" inside the command argument is not allowed then.
                    Also checks for a " to start a comment.
        -register   The first argument to the command can be an optional
                    register name (like :del, :put, :yank).
        -buffer     The command will only be available in the current buffer.
        -keepscript Do not use the location of where the user command was
                    defined for verbose messages, use the location of where
                    the user command was invoked.
```

In the cases of the -count and -register attributes, if the optional argument is supplied, it is removed from the argument list and is available to the replacement text separately.
Note that these arguments can be abbreviated, but that is a deprecated feature. Use the full name for new scripts.

Replacement text

The replacement text {repl} for a user defined command is scanned for special escape sequences, using <...> notation. Escape sequences are replaced with values from the entered command line, and all other text is copied unchanged. The resulting string is executed as an Ex command. To avoid the replacement use <lt> in place of the initial <. Thus to include "<bang>" literally use "<lt>bang>".

The valid escape sequences are

<line1>

<line1> The starting line of the command range.

<line2>

<line2> The final line of the command range.

<range>

<range> The number of items in the command range: 0, 1 or 2

<count>

<count> Any count supplied (as described for the '-range' and '-count' attributes).

<bang>

<bang> (See the '-bang' attribute) Expands to a ! if the command was executed with a ! modifier, otherwise expands to nothing.

<mods> <q-mods> :command-modifiers

<mods> The command modifiers, if specified. Otherwise, expands to nothing. Supported modifiers are :aboveleft, :belowright, :botright, :browse, :confirm, :hide, :horizontal, :keepalt, :keepjumps, :keepmarks, :keeppatterns, :leftabove, :lockmarks, :noautocmd, :noswapfile, :rightbelow, :sandbox, :silent, :tab, :topleft, :unsilent, :verbose, and :vertical.
Note that :filter is not supported.
Examples:

```
command! -nargs=+ -complete=file MyEdit
            \ for f in expand(<q-args>, 0, 1) |
            \ exe '<mods> split ' .. f |
            \ endfor

function! SpecialEdit(files, mods)
    for f in expand(a:files, 0, 1)
        exe a:mods .. ' split ' .. f
    endfor
endfunction
command! -nargs=+ -complete=file Sedit
            \ call SpecialEdit(<q-args>, <q-mods>)
```

<reg> <register>

<reg>   (See the '-register' attribute) The optional register, if specified. Otherwise, expands to nothing. <register> is a synonym for this.

<args>

<args> The command arguments, exactly as supplied (but as noted above, any count or register can consume some of the arguments, which are then not part of <args>).

<lt>   A single '<' (Less-Than) character. This is needed if you want to get a literal copy of one of these escape sequences into the expansion - for example, to get <bang>, use <lt>bang>.

<q-args>

If the first two characters of an escape sequence are "q-" (for example, <q-args>) then the value is quoted in such a way as to make it a valid value for use in an expression. This uses the argument as one single value. When there is no argument <q-args> is an empty string. See the q-args-example below.

<f-args>

To allow commands to pass their arguments on to a user-defined function, there is a special form <f-args> ("function args"). This splits the command arguments at spaces and tabs, quotes each argument individually, and the <f-args> sequence is replaced by the comma-separated list of quoted arguments. See the Mycmd example below. If no arguments are given <f-args> is removed.
   To embed whitespace into an argument of <f-args>, prepend a backslash. <f-args> replaces every pair of backslashes (\\) with one backslash. A backslash followed by a character other than white space or a backslash remains unmodified. Also see f-args-example below. Overview:

command	<f-args>
XX ab	"ab"
XX a\b	'a\b'
XX a\ b	'a b'
XX a\ b	'a ', 'b'
XX a\\b	'a\b'
XX a\\ b	'a\', 'b'
XX a\\\b	'a\\b'
XX a\\\ b	'a\ b'
XX a\\\\b	'a\\b'
XX a\\\\ b	'a\\', 'b'
XX	[nothing]

Note that if the "no arguments" situation is to be handled, you have to make
sure that the function can be called without arguments.

Examples for user commands:

```
" Delete everything after here to the end
:com Ddel +,$d

" Rename the current buffer
:com -nargs=1 -bang -complete=file Ren f <args>|w<bang>

" Replace a range with the contents of a file
" (Enter this all as one line)
:com -range -nargs=1 -complete=file
      Replace <line1>-pu_|<line1>,<line2>d|r <args>|<line1>d

" Count the number of lines in the range
:com! -range -nargs=0 Lines  echo <line2> - <line1> + 1 "lines"
```

f-args-example

Call a user function (example of <f-args>)

```
:com -nargs=* Mycmd call Myfunc(<f-args>)
```

When executed as:

```
:Mycmd arg1 arg2
```

This will invoke:

```
:call Myfunc("arg1","arg2")
```

q-args-example

A more substantial example:

```
:function Allargs(command)
:   let i = 0
:   while i < argc()
:         if filereadable(argv(i))
:            execute "e " .. argv(i)
:            execute a:command
:      endif
:      let i = i + 1
:   endwhile
:endfunction
:command -nargs=+ -complete=command Allargs call Allargs(<q-args>)
```

The command Allargs takes any Vim command(s) as argument and executes it on
all files in the argument list. Usage example (note use of the "e" flag to
ignore errors and the "update" command to write modified buffers):

```
:Allargs %s/foo/bar/ge|update
```

This will invoke:

```
:call Allargs("%s/foo/bar/ge|update")
```

Notable changes since Nvim 0.9

For changes in the previous release, see news-0.9.

BREAKING CHANGES

These changes may require adaptations in your config or plugins.

- API:
  - nvim_open_win() now blocks all autocommands when `noautocmd` is set, rather than just those from setting the `buffer` to display in the window.
- Defaults:
  - Default color scheme has been updated to be "Nvim branded" and accessible. Use `:colorscheme vim` to revert to the old legacy color scheme.
    - These Nvim specific highlight groups are now defined in a meaningfully different way and might need an update:
      - hl-FloatBorder is linked to hl-NormalFloat instead of hl-WinSeparator.
      - hl-NormalFloat is not linked to hl-Pmenu.
      - hl-WinBar has different background.
      - hl-WinBarNC is similar to hl-WinBar but not bold.
      - hl-WinSeparator is linked to hl-Normal instead of hl-VertSplit.
    - This also might result into some color schemes looking differently due to them relying on implicit assumptions about how highlight groups are defined by default. To account for this, define all attributes of highlight groups explicitly. Alternatively, use `:colorscheme vim` or `:source $VIMRUNTIME/colors/vim.lua` to restore previous definitions.
  - 'termguicolors' is enabled by default when Nvim is able to determine that the host terminal emulator supports 24-bit color.
- Editor:
  - When switching windows, CursorMoved autocommands trigger when Nvim is back on the main loop rather than immediately. This is more compatible with Vim.
  - "#" followed by a digit no longer stands for a function key at the start of the lhs of a mapping.
  - shm-q now fully hides macro recording message instead of only shortening it.
  - Signs placed through the legacy sign-commands are now stored and displayed as extmarks internally. Along with the following changes:
    - A sign placed twice in the same group with the same identifier will be moved.
    - Legacy signs are always deleted along with the line it is placed on.
    - Legacy and extmark signs will show up in both :sign-place-list and nvim_buf_get_extmarks().
    - Legacy and extmark signs are displayed and listed with the same priority: line number -> priority -> sign id -> recently placed
  - `:behave` was removed.
    - If you used `:behave xterm`, the following is equivalent:

      ```
      set mousemodel=extend
      ```

    - If you used `:behave mswin`, the following is equivalent:

      ```
      set selection=exclusive
      set selectmode=mouse,key
      set mousemodel=popup
      set keymodel=startsel,stopsel
      ```

- Events:
  - Returning any truthy value from a callback passed to nvim_create_autocmd() (rather than just `true`) will delete the autocommand.
- LSP:
  - LanguageTree:parse() will no longer parse injections by default and now requires an explicit range argument to be passed. If injections are required, provide an explicit range via `parser:parse({ start_row, end_row })`.
  - vim.lsp.util.parse_snippet() will now strictly follow the snippet grammar defined by LSP, and hence previously parsed snippets might now be considered invalid input.
  - vim.lsp.codelens.refresh() now takes an `opts` argument. With this change, the default behavior of just refreshing the current buffer has been replaced by refreshing all buffers.
  - vim.lsp.util.extract_completion_items() will no longer return reliable results, since it does not apply `itemDefaults` when its input is a `CompletionList`. Moreover, since support for LSP `completionList.itemDefaults` was added, some third party plugins might be negatively impacted in case the language servers support the feature but the plugin does not. If necessary, the respective capability can be removed when calling vim.lsp.protocol.make_client_capabilities().
  - LspRequest and LspProgressUpdate (renamed to LspProgress) autocmds were promoted from User autocmds to first class citizens.
- Lua:
  - -l ensures output ends with a newline if the script prints messages and doesn't cause Nvim to exit.
  - Removed functions from the vim.json module:
    - Unnecessary, undocumented functions which caused global side-effects.
    - `vim.json.null` is redundant with `vim.NIL`.
    - `vim.json.array_mt` (and related) is redundant with `vim.empty_dict()`.
  - vim.islist() now checks whether a table is actually list-like (i.e., has integer keys without gaps and starting from 1). For the previous behavior (only check for integer keys, allow gaps or not starting with 1), use vim.isarray().
  - Renamed `vim.treesitter.playground` to `vim.treesitter.dev`.
- Options:
  - Removed some Vim 5.0<= option compatibilities:
    - 'backspace' no longer supports number values. Instead:
      - for backspace=0 set backspace= (empty)
      - for backspace=1 set backspace=indent,eol
      - for backspace=2 set backspace=indent,eol,start (default behavior in Nvim)
      - for backspace=3 set backspace=indent,eol,nostop

    - 'backupdir' and 'directory' will no longer remove a > at the start of the option.
  - OptionSet autocommand args v:option_new, v:option_old, v:option_oldlocal, v:option_oldglobal now have the type of the option instead of always being strings. v:option_old is now the old global value for all global-local options, instead of just string global-local options.
  - Local value for a global-local number/boolean option is now unset when the option is set (e.g. using :set or nvim_set_option_value()) without a scope, which means they now behave the same way as string options.
- Plugins:
  - :TOhtml has been rewritten in Lua to support Nvim-specific decorations, and many options have been removed.
- Treesitter:
  - Treesitter highlight groups have been renamed to be more in line with upstream tree-sitter and Helix to make it easier to share queries. The full list is documented in treesitter-highlight-groups.
- TUI:
  - In some cases, the cursor in the Nvim TUI used to blink even without configuring 'guicursor' as mentioned in cursor-blinking. This was a bug that has now been fixed. If your cursor has stopped blinking, add the following (or similar, adapted to user preference) to your config file:

    ```
    set guicursor+=n-v-c:blinkon500-blinkoff500
    ```

NEW FEATURES

The following new features were added.

- API:
  - Passing 0 to nvim_get_chan_info() gets info about the current channel.
  - nvim_buf_set_extmark() supports inline virtual text.
  - nvim_win_text_height() computes the number of screen lines occupied by a range of text in a given window.
  - New RPC client type `msgpack-rpc` is added for nvim_set_client_info() to support fully MessagePack-RPC compliant clients.
  - Floating windows can now be hidden by setting `hide` in nvim_open_win() or nvim_win_set_config().
  - nvim_input_mouse() supports mouse buttons "x1" and "x2".
  - Added "force_crlf" option field in nvim_open_term().
  - Added nvim_tabpage_set_win() to set the current window of a tabpage.
  - Mapping APIs now support abbreviations when mode short-name has suffix "a".
  - Floating windows can now show footer with new `footer` and `footer_pos` config fields. Uses hl-FloatFooter by default.
  - extmarks can set a "url" highlight attribute, so the text region can become a clickable hyperlink (assuming UI support). The TUI renders URLs using the OSC 8 control sequence, enabling clickable text in supporting terminals.
  - nvim_open_win() and nvim_win_set_config() now support opening normal (split) windows, moving floating windows into split windows, and opening windows in non-current tabpages.
  - Flags added to nvim_buf_set_extmark():
    - "undo_restore": opt-out extmarks of precise undo tracking.
    - "invalidate": automatically hide or delete extmarks.
    - "virt_text_repeat_linebreak": repeat virtual text on wrapped lines.
  - Extmarks now fully support multi-line ranges, and a single extmark can be used to highlight a range of arbitrary length. The nvim_buf_set_extmark() API function already allowed you to define such ranges, but highlight regions were not rendered consistently for a range that covers more than one line break. This has now been fixed. Signs defined as part of a multi-line extmark also apply to every line in the range, not just the first. In addition, nvim_buf_get_extmarks() has gained an "overlap" option to return such ranges even if they started before the specified position.
- Defaults:
  - The `workspace/didChangeWatchedFiles` LSP client capability is now enabled by default on Mac and Windows. Disabled on Linux since there currently isn't a viable backend for watching files that scales well for large directories.
  - On Windows 'isfname' does not include ":". Drive letters are handled correctly without it. (Use gF for filepaths suffixed with ":line:col").
  - 'comments' includes "fb:•".
  - 'shortmess' includes the "C" flag.
  - 'grepprg' uses the -H and -I flags for grep by default, and defaults to using ripgrep if available.
  - "]d" and "[d" in Normal mode map to vim.diagnostic.goto_next() and vim.diagnostic.goto_prev(), respectively.]d-default [d-default
  - <C-W>d (and <C-W><C-D>) map to vim.diagnostic.open_float() CTRL-W_d-default
  - vim.lsp.start() sets the following default keymaps (assuming server support):
    - K in Normal mode maps to vim.lsp.buf.hover(), unless 'keywordprg' was customized before calling vim.lsp.start().
  - Automatic linting of treesitter query files (see ft-query-plugin). Can be disabled via:

    ```
    vim.g.query_lint_on = {}
    ```

  - Enabled treesitter highlighting for:
    - Treesitter query files
    - Vim help files
    - Lua files
- Editor:
  - Better cmdline completion for string option value. complete-set-option
    - Try it with `:set listchars=<Tab>`
  - By default, the swapfile "ATTENTION" E325 dialog is skipped if the swapfile is owned by a running Nvim process, instead of prompting. If you always want the swapfile dialog, delete the default SwapExists handler: `autocmd! nvim.swapfile`. default-autocmds
  - Navigating the jumplist with CTRL+O, CTRL+I behaves more intuitively when deleting buffers, and avoids "invalid buffer" cases. #25461
  - :fclose command.
  - v_Q-default and v_@-default repeat a register for each line of a linewise visual selection.
  - Clicking on a tabpage in the tabline with the middle mouse button closes it.
  - :checkhealth buffer can be opened in a split window using modifiers like :vertical, :horizontal and :botright.
- Events:
  - vim.on_key() callbacks receive a second argument for keys typed before mappings are applied.
- LSP:

    - LSP method names are available in `vim.lsp.protocol.Methods`.
    - Implemented LSP inlay hints: lsp-inlay_hint https://microsoft.github.io/language-server-protocol/specification/#textDocument_inlayHint
    - Implemented pull diagnostic textDocument/diagnostic: vim.lsp.diagnostic.on_diagnostic() https://microsoft.github.io/language-server-protocol/specification/#textDocument_diagnostic
    - Implemented LSP type hierarchy: vim.lsp.buf.typehierarchy() https://microsoft.github.io/language-server-protocol/specification/#textDocument_prepareTypeHierarchy
    - vim.lsp.status() consumes the last progress messages as a string.
    - LSP client now always saves and restores named buffer marks when applying text edits.
    - LSP client now supports the `positionEncoding` server capability. If a server responds with the `positionEncoding` capability in its initialization response, Nvim automatically sets the client's `offset_encoding` field.
    - Dynamic registration of LSP capabilities. An implication of this change is that checking a client's `server_capabilities` is no longer a sufficient indicator to see if a server supports a feature. Instead use `client.supports_method(<method>)`. It considers both the dynamic capabilities and static `server_capabilities`.
    - `anchor_bias` option to lsp-handlers aids in positioning of floating windows.
    - vim.lsp.util.locations_to_items() sets the `user_data` of each item to the original LSP `Location` or `LocationLink`.
    - Added support for connecting to servers using named pipes (Windows) or Unix domain sockets (Unix) via vim.lsp.rpc.connect().
    - Added support for `completionList.itemDefaults`, reducing overhead when computing completion items where properties often share the same value (e.g. `commitCharacters`). Note that this might affect plugins and language servers that don't support the feature, and in such cases the respective capability can be unset.
    - vim.lsp.start() accepts a "silent" option for suppressing messages if an LSP server failed to start.
    - vim.lsp.buf.definition(), vim.lsp.buf.declaration(), vim.lsp.buf.type_definition(), and vim.lsp.buf.implementation() now support the `loclist` field of vim.lsp.ListOpts.
- Lua:
    - :lua with a [range] executes that range as Lua code, in any buffer.
    - :source without arguments treats a buffer with 'filetype' of "lua" as Lua code regardless of its extension.
    - Vimscript function exists() supports checking v:lua functions.
    - vim.iter() is a generic interface for all iterable objects (tables, iterators).
    - vim.snippet provides a mode for expanding and navigating snippets.
    - vim.ringbuf() is a generic ring buffer (data structure).
    - vim.deepcopy() gained a `noref` argument to avoid hashing table values.
    - vim.keycode() translates keycodes in a string.
    - vim.system() runs commands / starts processes.
    - vim.lpeg and vim.re expose the bundled Lpeg expression grammar parser and its regex interface.
    - vim.base64.encode() and vim.base64.decode() encode and decode strings using Base64 encoding.
    - vim.text.hexencode() and vim.text.hexdecode() convert strings to and from byte representations.
    - vim.ui.open() opens URIs using the system default handler (macOS `open`, Windows `explorer`, Linux `xdg-open`, etc.)
    - vim.wo can now be double indexed for :setlocal behaviour. Currently only `0` for the buffer index is supported.
    - Improved messages for type errors in `vim.api.*` calls (including `opts` params).
    - Lua type annotations for:
        - `vim.*`
        - `vim.fn.*`
        - `vim.api.*`
        - `vim.v.*`
    - Functions that take a severity as an optional parameter (e.g. vim.diagnostic.get()) now also accept a list of severities vim.diagnostic.severity
    - vim.diagnostic.count() returns the number of diagnostics for a given buffer and/or namespace, by severity. This is a faster alternative to vim.diagnostic.get() when only the number of diagnostics is needed, but not the diagnostics themselves.
    - vim.diagnostic.is_enabled()
    - vim.version.le(), vim.version.ge()
    - vim.fs.root() finds project root directories from a list of "root markers".
    - vim.tbl_contains() now works for general tables and allows specifying a predicate function that is checked for each value. (Use vim.list_contains() for checking list-like tables (integer keys without gaps) for literal values.)
    - vim.region() can use a string accepted by getpos() as position.
- Options:
    - 'winfixbuf' keeps a window focused onto a specific buffer
    - 'smoothscroll' option to scroll by screen line rather than by text line when 'wrap' is set.
    - 'foldtext' now supports virtual text format. fold-foldtext
    - 'foldtext' can be set to an empty string to disable and render the line: as normal with regular highlighting and no line wrapping.
    - 'complete' option supports "f" flag for completing buffer names.
    - 'completeopt' option supports "popup" flag to show extra information in a floating window.
    - 'errorfile' (-q) accepts `-` as an alias for stdin.
- Performance:
    - 'diffopt' "linematch" scoring algorithm now favours larger and less groups https://github.com/neovim/neovim/pull/23611
    - Treesitter highlighting now parses injections incrementally during screen redraws only for the line range being rendered. This significantly improves performance in large files with many injections.
    - 'breakindent' performance is significantly improved for wrapped lines.
    - Cursor movement, insertion with [count] and screenpos() are now faster.
- Plugins:
    - Nvim now includes commenting support.
    - :Man supports the `:hide` modifier to open page in the current window.
    - :Man respects 'wrapmargin'
- Startup:
    - $NVIM_APPNAME can be set to a relative path instead of only a name.
    - --startuptime reports startup times for both processes (TUI + server) as separate sections.
- Terminal:
    - :terminal accepts some :command-modifiers (specifically :horizontal and those that affect splitting a window).
    - Terminal buffers emit a TermRequest autocommand event when the child process emits an OSC or DCS control sequence.

    - Terminal buffers respond to OSC background and foreground requests. default-autocmds
- Treesitter:
    - Bundled parser and queries (highlight, folds) for Markdown (used for LSP hover).
    - :InspectTree shows root nodes.
    - :InspectTree now supports folding.
    - :InspectTree shows node ranges in 0-based instead of 1-based indexing.
    - vim.treesitter.foldexpr() now recognizes folds captured using a quantified query pattern.
    - vim.treesitter.query.omnifunc() provides completion in treesitter query files (set by default).
    - vim.treesitter.query.edit() provides live editing of treesitter queries.
    - Query:iter_matches() now has the ability to set the maximum start depth for matches.
    - `@injection.language` now has smarter resolution and will fall back to language aliases (e.g., filetype or custom shorthands) registered via vim.treesitter.language.register() and/or attempt lower case variants of the text.
    - `@injection.filename` will try to match the node text via vim.filetype.match() and treat the result as a language name in the same way as `@injection.language`.
    - The `#set!` directive supports `injection.self` and `injection.parent` for injecting either the current node's language or the parent LanguageTree's language, respectively.
    - The `#set!` directive can set the "url" property of a node to have the node emit a hyperlink. Hyperlinks are UI specific: in the TUI, the OSC 8 control sequence is used.
    - Improved error messages for query parsing.
- TUI:
    - Builtin TUI can now recognize "super" (<D-) and "meta" (<T-) modifiers in a terminal emulator that supports tui-csiu.
    - The TermResponse event can be used with v:termresponse to read escape sequence responses from the host terminal.
    - A clipboard provider which uses OSC 52 to copy the selection to the system clipboard is now bundled by default and will be automatically enabled under certain conditions. clipboard-osc52
    - 'termsync' option asks the host terminal to buffer screen updates until the redraw cycle is complete. Requires support from the host terminal.
- UI:
    - Enhanced support for rendering multibyte characters using composing characters: the maximum limit was increased from 1+6 codepoints to 31 bytes, which is guaranteed to fit all chars from before but often more.
        - **NOTE:** the regexp engine still has a hard-coded limit of considering 6 composing chars only.

CHANGED FEATURES

These existing features changed their behavior.

- API:
    - nvim_buf_call() and nvim_win_call() now preserve any return value (NB: not multiple return values)
- Editor:
    - gx now uses vim.ui.open() and not netrw. To customize, you can redefine `vim.ui.open` or remap `gx`. To continue using netrw (deprecated):

      ```
      :packadd netrw
      :call netrw#BrowseX(expand(exists("g:netrw_gx") ? g:netrw_gx : '<cfile>'), netrw#CheckIfRemote())<CR>
      ```

- LSP:
    - LSP hover and signature help now use Treesitter for highlighting of Markdown content. Note that highlighting of code examples requires a matching parser and may be affected by custom queries.
    - LspRequest autocmd callbacks contain more information about the LSP request status update that occurred.
- Lua:
    - vim.wait() cannot be called in api-fast.
    - vim.diagnostic.config() now accepts virtual text relevant options to nvim_buf_set_extmark() (e.g. "virt_text_pos" and "hl_mode") in its "virtual_text" table, which gives users more control over how diagnostic virtual text is displayed.
    - vim.diagnostic.get() and vim.diagnostic.count() accept multiple namespaces rather than just a single namespace.
    - vim.diagnostic.enable() gained new parameters, and the old signature is deprecated.
    - vim.diagnostic.config() now accepts a function for the virtual_text.prefix option, which allows for rendering e.g., diagnostic severities differently.
- Options:
    - Attempting to set an invalid keycode option (e.g. `set t_foo=123`) no longer gives an error.
- Terminal:
    - Terminal buffers started with no arguments (and use 'shell') close automatically if the job exited without error, eliminating the (often unwanted) "[Process exited 0]" message. default-autocmds
- Treesitter:
    - Query:iter_matches(), vim.treesitter.query.add_predicate(), and vim.treesitter.query.add_directive() accept a new `all` option which ensures that all matching nodes are returned as a table. The default option `all=false` returns only a single node, breaking captures with quantifiers like `(comment)+ @comment`; it is only provided for backward compatibility and will be removed after Nvim 0.10.
    - vim.treesitter.query.add_predicate() and vim.treesitter.query.add_directive() now accept an options table rather than a boolean "force" argument. To force a predicate or directive to override an existing predicate or directive, use `{ force = true }`.

REMOVED FEATURES

These deprecated features were removed.

- Vimball support, including `:Vimuntar` command
- Support for legacy treesitter injection queries
- 'shortmess' flags:
    - shm-f. Always use "(3 of 5)", never "(file 3 of 5)".
    - shm-i. Always use "[noeol]".
    - shm-x. Always use "[dos]", "[unix]" and "[mac]".

- shm-n. Always use "[New]".

DEPRECATIONS

See deprecated-0.10.

Notable changes since Nvim 0.10

For changes in the previous release, see news-0.10.

BREAKING CHANGES

These changes may require adaptations in your config or plugins.

API

- `vim.rpcnotify(0)` and `rpcnotify(0)` broadcast to ALL channels. Previously they would "multicast" only to subscribed channels (controlled by `nvim_subscribe()`). Plugins and clients that want "multicast" behavior must now maintain their own list of channels.
  - In the future, vim.rpcnotify() may accept a list of channels, if there is demand for this use-case.
- "Dictionary" was renamed to "Dict" internally and in the RPC api-metadata. This is not expected to break clients because there are no known clients that actually use the `return_type` field or the parameter type names reported by --api-info or nvim_get_api_info().
- Renamed `nvim__id_dictionary` (unsupported/experimental API) to `nvim__id_dict`.

BUILD

- On Windows, only building with the UCRT runtime is supported.
- Translations are turned off by default. Enable by building Nvim with the CMake flag `ENABLE_TRANSLATIONS=ON`.

DIAGNOSTICS

- The "underline" diagnostics handler sorts diagnostics by severity when using the "severity_sort" option.
- Diagnostics are filtered by severity before being passed to a diagnostic handler diagnostic-handlers.
- The "virtual_text" handler is disabled by default. Enable with

```
vim.diagnostic.config({ virtual_text = true })
```

EDITOR

- The order in which signs are placed was changed. Higher priority signs will now appear left of lower priority signs.
- hl-CurSearch now behaves the same as Vim and no longer updates on every cursor movement.
- Moving in the buffer list using :bnext and similar commands behaves as documented and skips help buffers if run from a non-help buffer, otherwise it moves to another help buffer.
- Bells from a terminal buffer are now silent by default, unless 'belloff' option doesn't contain "term" or "all".
- Renamed autocmd group `nvim_swapfile` to `nvim.swapfile`. default-autocmds If you always want the swapfile dialog, delete the `nvim.swapfile` group: `autocmd! nvim.swapfile`.

EVENTS

- vim.ui_attach() callbacks for ui-messages `msg_show` events are executed in api-fast context.
- New/enhanced arguments in these existing UI events:
  - `cmdline_hide`: Includes `level` and `abort` arguments, `abort` argument indicating if the cmdline was aborted.
  - `cmdline_show`:
    - Prompts that were previously emitted as `msg_show` events, are now routed through `cmdline_show`.
    - `hl_id` argument to highlight the prompt text.
  - `msg_show`:
    - `history` argument indicating if the message was added to the history.
    - new message kinds: "bufwrite", "completion", "list_cmd", "lua_print", "search_cmd", "shell_out/err/ret", "undo", "verbose", wildlist".
- TermRequest and TermResponse event-data is now a table. The "sequence" field contains the received sequence. TermRequest also contains a "cursor" field indicating the cursor's position when the sequence was received.

HIGHLIGHTS

- TermCursorNC is removed and no longer supported. Unfocused terminals no longer have a cursor.

LSP

- vim.lsp.buf.references(), vim.lsp.buf.declaration(), vim.lsp.buf.definition(), vim.lsp.buf.type_definition(), vim.lsp.buf.implementation() and vim.lsp.buf.hover() now support merging the results of multiple clients but no longer trigger the global handlers from `vim.lsp.handlers`
- vim.lsp.buf.typehierarchy() now passes the correct params for each client request.
- vim.lsp.handlers.signature_help() is no longer used.
- vim.lsp.diagnostic.on_publish_diagnostics() and vim.lsp.diagnostic.on_diagnostic() no longer accept a config parameter and can no longer be configured with vim.lsp.with(). Instead use:

```
vim.diagnostic.config(config, vim.lsp.diagnostic.get_namespace(client_id))
```

- vim.lsp.util.make_position_params(), vim.lsp.util.make_range_params() and vim.lsp.util.make_given_range_params() now require the `position_encoding` parameter.
- vim.lsp.util.symbols_to_items() now requires the `position_encoding` parameter.

LUA

- API functions now consistently return an empty dictionary as vim.empty_dict(). Earlier, a lua-special-tbl was sometimes used.
- vim.json.encode() no longer escapes forward slashes "/" by default

OPTIONS

- The 'statuscolumn' `%l` item can now be used as a number column segment that changes according to related options. It takes care of alignment, 'number', 'relativenumber' and 'signcolumn' set to "number". The now redundant `%r` item is no longer treated specially for 'statuscolumn'.
- `:set {option}<` removes the local value for all global-local options instead of just string global-local options.
- `:setlocal {option}<` copies the global value to the local value for number and boolean global-local options instead of removing the local value.
- Setting hidden-options now gives an error. In particular, setting 'noshellslash' is now only allowed on Windows.

TREESITTER

- Query:iter_matches() correctly returns all matching nodes in a match instead of only the last node. This means that the returned table maps capture IDs to a list of nodes that need to be iterated over. For backwards compatibility, an option `all=false` (only return the last matching node) is provided that will be removed in a future release.
- vim.treesitter.language.get_filetypes() always includes the `{language}` argument in addition to explicitly registered filetypes.
- vim.treesitter.language.get_lang() falls back to the `{filetype}` argument if no languages are explicitly registered.
- vim.treesitter.language.add() returns `true` if a parser was loaded successfully and `nil,errmsg` otherwise instead of throwing an error.
- vim.treesitter.get_parser() and vim.treesitter.start() no longer parse the tree before returning. Scripts must call LanguageTree:parse() explicitly.

```
local p = vim.treesitter.get_parser(0, 'c')
p:parse()
```

- vim.treesitter.get_parser() expects its buffer to be loaded.

TUI

- OSC 52 is used as a fallback clipboard provider when no other clipboard-tool is found, even when not using SSH clipboard-osc52. To disable OSC 52 queries, set the "osc52" key of g:termfeatures to false.

VIMSCRIPT

- v:msgpack_types has the type "binary" removed. msgpackparse() no longer treats BIN, STR and FIXSTR as separate types. Any of these is returned as a string if possible, or a blob if the value contained embedded NUL:s.

NEW FEATURES

The following new features were added.

API

- Improved API "meta" docstrings and :help documentation.
- nvim__ns_set() can set properties for a namespace
- nvim_echo() `err` field to print error messages and chunks accepts highlight group IDs.
- nvim_open_win() supports a `mouse` field that allows configuring mouse interaction with the window separately from `focusable` field.
- nvim_open_win() `relative` field can be set to "laststatus" and "tabline".
- Additions to nvim_buf_set_extmark():
  - `conceal_lines` field to conceal an entire line.
  - `hl_group` field can be an array of layered groups.
  - `virt_text_pos` field accepts value `eol_right_align` to allow for right aligned text that truncates before covering up buffer text.
  - `virt_lines_overflow` field accepts value `scroll` to enable horizontal scrolling for virtual lines with 'nowrap'.

DEFAULTS

- Highlighting:
  - Improved styling of :checkhealth and :help buffers.
- Mappings:
  - grn in Normal mode maps to vim.lsp.buf.rename()
  - grr in Normal mode maps to vim.lsp.buf.references()
  - gri in Normal mode maps to vim.lsp.buf.implementation()
  - gO in Normal mode maps to vim.lsp.buf.document_symbol()
  - gra in Normal and Visual mode maps to vim.lsp.buf.code_action()
  - CTRL-S in Insert and Select mode maps to vim.lsp.buf.signature_help()
  - Mouse popup-menu includes an "Open in web browser" item when you right-click on a URL.
  - Mouse popup-menu includes a "Go to definition" item when LSP is active in the buffer.
  - Mouse popup-menu includes "Show Diagnostics", "Show All Diagnostics" and "Configure Diagnostics" items when there are diagnostics in the buffer.
  -]d-default and [d-default accept a count.
  - [D-default and]D-default jump to the first and last diagnostic in the current buffer, respectively.
  - Mappings inspired by Tim Pope's vim-unimpaired:
    - [q,]q, [Q,]Q, [_CTRL-Q,]_CTRL-Q navigate through the quickfix list
    - [l,]l, [L,]L, [_CTRL-L,]_CTRL-L navigate through the location-list
    - [t,]t, [T,]T, [_CTRL-T,]_CTRL-T navigate through the tag-matchlist
    - [a,]a, [A,]A navigate through the argument-list
    - [b,]b, [B,]B navigate through the buffer-list
    - [<Space>,]<Space> add an empty line above and below the cursor

    - [[and]] in Normal mode jump between shell prompts for shells which emit OSC 133 sequences ("shell integration" or "semantic prompts").
- Options:
    - 'diffopt' default includes "linematch:40".
    - 'number', 'relativenumber', 'signcolumn', and 'foldcolumn' are disabled in terminal buffers. terminal-config shows how to change these defaults.
    - Lua ftplugin sets 'omnifunc' to "v:lua.vim.lua_omnifunc".
    - Lua ftplugin sets 'foldexpr' to "v:lua.vim.treesitter.foldexpr()".
- Snippet:
    - <Tab> in Insert and Select mode maps to `vim.snippet.jump({ direction = 1 })` when a snippet is active and jumpable forwards.
    - <S-Tab> in Insert and Select mode maps to `vim.snippet.jump({ direction = -1 })` when a snippet is active and jumpable backwards.

DIAGNOSTICS

- vim.diagnostic.config() accepts a "jump" table to specify defaults for vim.diagnostic.jump().
- A "virtual_lines" diagnostic handler was added to render diagnostics using virtual lines below the respective code.
- The "virtual_text" diagnostic handler accepts a `current_line` option to only show virtual text at the cursor's line.

EDITOR

- Improved paste handling for redo (dot-repeat) and macros (recording):
    - Redoing a large paste is significantly faster and ignores 'autoindent'.
    - Replaying a macro with @ also replays pasted text.
- On Windows, filename arguments on the command-line prefixed with "~\" or "~/" are now expanded to the user's profile directory, not a relative path to a literal "~" directory.
- hl-ComplMatchIns shows matched text of the currently inserted completion.
- hl-PmenuMatch and hl-PmenuMatchSel show matched text in completion popup.
- gO now works in `help`, `checkhealth`, and `markdown` buffers.
- Jump between sections in `help` and `checkhealth` buffers with `[[` and `]]`.

EVENTS

- CompleteDone now sets the `reason` key in `v:event` which specifies the reason for completion being done.
- vim.on_key() callbacks can consume the key by returning an empty string.

LSP

- Improved rendering of LSP hover docs. K-lsp-default
- vim.lsp.completion.enable() gained the `convert` callback which enables customizing the transformation of an LSP CompletionItem to complete-items.
- vim.lsp.diagnostic.from() can be used to convert a list of vim.Diagnostic objects into their LSP diagnostic representation.
- `:checkhealth vim.lsp` displays the server version (if available).
- Completion side effects (including snippet expansion, execution of commands and application of additional text edits) is now built-in.
- vim.lsp.util.locations_to_items() and vim.lsp.util.symbols_to_items() now sets `end_col` and `end_lnum` fields.
- vim.lsp.buf.format() now supports passing a list of ranges via the `range` parameter (this requires support for the `textDocument/rangesFormatting` request).
- vim.lsp.buf.code_action() actions show client name when there are multiple clients.
- vim.lsp.buf.signature_help() can now cycle through different signatures using <C-s> and also support multiple clients.
- The client now supports `'utf-8'` and `'utf-32'` position encodings.
- vim.lsp.buf.hover() now highlights hover ranges using the hl-LspReferenceTarget highlight group.
- Functions in vim.lsp.Client can now be called as methods.
- Implemented LSP folding: vim.lsp.foldexpr() https://microsoft.github.io/language-server-protocol/specification/#textDocument_foldingRange
- vim.lsp.config() has been added to define default configurations for servers. In addition, configurations can be specified in `lsp/<name>.lua`.
- vim.lsp.enable() has been added to enable servers.
- vim.lsp.buf.code_action() resolves the `command` property during the `codeAction/resolve` request.
- The `textDocument/completion` request now includes the completion context in its parameters.

LUA

- Command-line completions for: `vim.g`, `vim.t`, `vim.w`, `vim.b`, `vim.v`, `vim.o`, `vim.wo`, `vim.bo`, `vim.opt`, `vim.opt_local`, `vim.opt_global`, `vim.env` and `vim.fn`.
- Documentation for lua-bit.
- gf in Lua buffers can go to module in same repo, runtime-search-path and package.path.
- vim.fs.rm() can delete files and directories.
- vim.validate() now has a new signature which uses less tables, is more performant and easier to read.
- vim.str_byteindex() and vim.str_utfindex() gained overload signatures supporting two new parameters, `encoding` and `strict_indexing`.
- vim.json.encode() has an option to enable forward slash escaping
- vim.fs.abspath() converts paths to absolute paths.
- vim.fs.relpath() gets relative path compared to base path.
- vim.fs.dir() and vim.fs.find() can now follow symbolic links, the behavior can be turn on using the new `follow` option.
- vim.hl.range() now has a optional `timeout` field which allows for a timed highlight.
- vim.text.indent() indents/dedents text.

OPTIONS

- 'completeopt' flag "fuzzy" enables fuzzy-matching during ins-completion.

- 'completeopt' flag "preinsert" highlights text to be inserted.
- 'wildmode' flag "noselect" shows 'wildmenu' without selecting an entry.
- 'messagesopt' configures :messages and hit-enter prompt.
- 'tabclose' controls which tabpage to focus when closing a tabpage.
- 'eventignorewin' to persistently ignore events in a window.
- 'winborder' sets the default border for floating-windows.

PERFORMANCE

- Significantly reduced redraw time for long lines with treesitter highlighting.
- LSP diagnostics and inlay hints are de-duplicated (new requests cancel inflight requests). This greatly improves performance with slow LSP servers.
- 10x speedup for vim.treesitter.foldexpr() (when no parser exists for the buffer).
- Strong treesitter-query caching makes repeat vim.treesitter.query.get() and vim.treesitter.query.parse() calls significantly faster for large queries.
- Treesitter highlighting is now asynchronous. To force synchronous parsing, use `vim.g._ts_force_sync_parsing = true`.
- Treesitter folding is now calculated asynchronously.
- LanguageTree:parse() now only runs the injection query on the provided range (as long as the language does not have a combined injection), significantly improving treesitter-highlight performance.
- Treesitter injection query iteration is now asynchronous, making edits in large buffers with combined injections much quicker.
- 10x reduction in blocking time when attaching an LSP to a large buffer.

PLUGINS

- EditorConfig
  - spelling_language property is now supported.
- 'inccommand' incremental preview can run on 'nomodifiable' buffers and restores their 'modifiable' state
- Commenting
  - 'commentstring' values can now be specified in a Treesitter capture's `bo.commentstring` metadata field, providing finer grained support for languages like JSX.

STARTUP

- -es ("script mode") disables shada by default.
- Nvim will fail if the --listen or $NVIM_LISTEN_ADDRESS address is invalid, instead of silently skipping an invalid address.

TERMINAL

- The terminal now understands the OSC 52 escape sequence to write to the system clipboard (copy). Querying with OSC 52 (paste) is not supported.
- hl-StatusLineTerm and hl-StatusLineTermNC define highlights for the status line in terminal windows.
- The terminal buffer now supports reflow (wrapped lines adapt when the buffer is resized horizontally). **Note:** Lines that are not visible and kept in 'scrollback' are not reflown.
- The terminal now supports OSC 8 escape sequences and will display hyperlinks in supporting host terminals.
- The terminal now uses the actual cursor, rather than a "virtual" cursor. This means that escape codes sent by applications running in a terminal buffer can change the cursor shape and visibility. However, it also means that the TermCursorNC highlight group is no longer supported: an unfocused terminal window will have no cursor at all (so there is nothing to highlight).
- jobstart() gained the "term" flag.
- The terminal will send theme update notifications when 'background' is changed and DEC mode 2031 is enabled.
- The terminal has experimental support for the Kitty keyboard protocol (sometimes called "CSI u" key encoding). Only the "Disambiguate escape codes" mode is currently supported.
- The terminal emits a TermRequest autocommand event when the child process emits an APC control sequence.
- TermRequest has a "cursor" field in its event-data indicating the cursor position when the sequence was received.

TREESITTER

- LanguageTree:node_for_range() gets anonymous and named nodes for a range
- vim.treesitter.get_node() now takes an option `include_anonymous`, default false, which allows it to return anonymous nodes as well as named nodes.
- treesitter-directive-trim! can trim all whitespace (not just empty lines) from both sides of a node.
- vim.treesitter.get_captures_at_pos() now returns the `id` of each capture
- New TSNode:child_with_descendant(), which efficiently gets the node's child that contains a given node as descendant.
- LanguageTree:parse() optionally supports asynchronous invocation, which is activated by passing the `on_parse` callback parameter.
- vim.treesitter.query.set() can now inherit and/or extend runtime file queries in addition to overriding.
- LanguageTree:is_valid() now accepts a range parameter to narrow the scope of the validity check.
- :InspectTree now shows which nodes are missing.
- Bundled markdown highlight queries use `conceal_lines` metadata to conceal code block fence lines vertically.
- vim.treesitter.language.inspect() shows additional information, including parser version for ABI 15 parsers.
- TSQuery:disable_pattern() and TSQuery:disable_capture() to turn off a specific pattern or capture in a query.
- vim.treesitter.get_captures_at_pos() returns the `pattern_id` of the pattern used to match each capture.
- Query:iter_captures() now accepts an `opts` parameter, similar to Query:iter_matches().

TUI

- The builtin UI declares info nvim_set_client_info() on its channel. See startup-tui. To see the current UI info, try this:

```
:lua =vim.api.nvim_get_chan_info(vim.api.nvim_list_uis()[1].chan)
```

- log messages written by the builtin UI client (TUI, --remote-ui) are now prefixed with "ui" instead of "?".
- The TUI will re-query the terminal's background color when a theme update notification is received and Nvim will update 'background' accordingly.

UI

- :detach the current UI, let the Nvim server continue running as a background process. Works with the builtin TUI, and all GUIs.
- vim.ui.open() (by default bound to gx) accepts an `opt.cmd` parameter which controls the tool used to open the given path or URL. If you want to globally set this, you can override vim.ui.open using the same approach described at vim.paste().
- `vim.ui.open()` now supports [lemonade](https://github.com/lemonade-command/lemonade) as an option for opening urls/files. This is handy if you are in an ssh connection and use `lemonade`.
- The ins-completion-menu now supports cascading highlight styles. hl-PmenuSel and hl-PmenuMatch both inherit from hl-Pmenu, and hl-PmenuMatchSel inherits highlights from both hl-PmenuSel and hl-PmenuMatch.
- vim.diagnostic.setqflist() updates an existing quickfix list with the given title if found
- ui-messages content chunks now also contain the highlight group ID.
- :checkhealth can display in a floating window, controlled by the g:health variable.

VIMSCRIPT

- getchar() and getcharstr() have optional `{opts}` Dict argument to control: cursor behavior, return type, and whether to simplify the returned key.

CHANGED FEATURES

These existing features changed their behavior.

- 'scrollbind' now works properly with buffers that contain virtual lines.

Scrollbind works by aligning to a target top line of each window in a tab page. Previously this was done by calculating the difference between the old top line and the target top line, and scrolling by that amount. Now the top lines are calculated using screen line numbers which take virtual lines into account.

- The implementation of grapheme clusters (or combining chars mbyte-combining) was upgraded to closely follow extended grapheme clusters as defined by UAX#29 in the unicode standard. Noteworthily, this enables proper display of many more emoji characters than before, including those encoded with multiple emoji codepoints combined with ZWJ (zero width joiner) codepoints.

This also applies to :terminal output, where width of cells will be calculated using the upgraded implementation.

- Custom highlights in 'rulerformat', 'statuscolumn', 'statusline', 'tabline', 'winbar', and the sign/number column are stacked with their respective highlight groups, as opposed to hl-Normal. This is also reflected in the `highlights` from nvim_eval_statusline(), with a new `groups` field containing an array of stacked highlight groups.
- vim.on_key() callbacks won't be invoked recursively when a callback itself consumes input.
- "q" in man pages now uses CTRL-W_q instead of CTRL-W_c to close the current window, and it no longer throws E444 when there is only one window on the screen. Global variable `vim.g.pager` is removed.
- Default 'titlestring' is now implemented with 'statusline' "%" format items. This means the default, empty value is essentially an alias to: `%t%(\ %M%)%(\ \(%{expand(\"%:~:h\")}\)%)%a\ -\ Nvim`. This is only an implementation simplification, not a behavior change.

REMOVED FEATURES

These deprecated features were removed.

- option `severity_limit` for `vim.lsp.diagnostic` (use `min=severity` instead vim.diagnostic.severity).

DEPRECATIONS

See deprecated-0.11.

Notable changes since Nvim 0.11

For changes in the previous release, see news-0.11.

BREAKING CHANGES

These changes may require adaptations in your config or plugins.

API

- nvim_get_commands() returns `complete` as a Lua function, if it was defined as such.

DIAGNOSTICS

- diagnostic-signs can no longer be configured with :sign-define or sign_define() (deprecated in Nvim 0.10 deprecated-0.10).
- Removed vim.diagnostic.disable() and vim.diagnostic.is_disabled() (deprecated in Nvim 0.10 deprecated-0.10).
- The legacy signature of vim.diagnostic.enable() (deprecated in Nvim 0.10 deprecated-0.10) is no longer supported.

EDITOR

- i_CTRL-R inserts named/clipboard registers (A-Z,a-z,0-9+) literally, like pasting instead of like user input. Improves performance, avoids broken formatting. To get the old behavior you can use `<C-R>=@x`.
- Parsing of URI-like buffer names more closely follows RFC3986, so for example "svn+ssh:", "ed2k:", and "iris.xpc:" are recognized as URI schemes.
- Security: Nvim on Windows no longer searches the current directory for external command executables; prefix a relative or absolute path if you want the old behavior $NoDefaultCurrentDirectoryInExePath.

EVENTS

- ui-messages no longer emits the `msg_show.return_prompt`, and `msg_history_clear` events. The `msg_clear` event was repurposed and is now emitted after the screen is cleared. These events arbitrarily assumed a message UI that mimics the legacy message grid. Benefit: reduced UI event traffic and more flexibility for UIs. The `msg_history_show` event has an additional "prev_cmd" argument.

LSP

- JSON "null" values in LSP messages are represented as vim.NIL instead of `nil`. Missing fields (as opposed to JSON "null") are still represented as `nil`.
- The function set with vim.lsp.log.set_format_func() is now given all arguments corresponding to a log entry instead of the individual arguments.
- Renamed `vim.lsp.semantic_tokens start()/stop()` to `enable()`.
- vim.lsp.util.convert_signature_help_to_markdown_lines() activeParameter handling updated:
  - Values < 0 are now treated as `nil` instead of 0.
  - Values outside the range of `signatures[activeSignature].parameters` are now treated as `nil` instead of `#signatures[activeSignature].parameters`

LUA

- Renamed `vim.diff` to `vim.text.diff`.

OPTIONS

- 'shelltemp' defaults to "false".

PLUGINS

- Removed "shellmenu" plugin, an old menu-based quasi-snippet plugin for shell scripts.
- package-tohtml is now an "opt-in" plugin. Use :packadd to activate it:

```
:packadd nvim.tohtml
```

TREESITTER

- ft-query-plugin no longer enables vim.treesitter.query.lint() by default.
- treesitter-directive-offset! can now be applied to quantified captures. It no longer sets `metadata[capture_id].range`; it instead sets `metadata[capture_id].offset`. The offset will be applied in vim.treesitter.get_range(), which should be preferred over reading metadata directly for retrieving node ranges.
- The "all" option to Query:iter_matches(), which was introduced in Nvim 0.11 to aid in transitioning to the new behavior, has been removed.

NEW FEATURES

The following new features were added.

API

- api-contract allows existing functions to change return-type from `void => non-void`.
- nvim_win_text_height() can limit the lines checked when a certain `max_height` is reached, and returns the `end_row` and `end_vcol` for which `max_height` or the calculated height is reached.
- vim.secure.read() now returns `true` for trusted directories. Previously it would return `nil`, thus impossible to tell if the directory was actually trusted.

- nvim_ui_send() writes arbitrary data to a UI's stdout. Use this to write escape sequences to the terminal when Nvim is running in the TUI.
- nvim_echo() can set the ui-messages kind with which to emit the message.
- nvim_echo() can create Progress messages
- nvim_get_commands() returns `preview` and `callback` as Lua functions if they were so specified in `nvim_create_user_command()`.
- nvim_open_tabpage() can open a new tabpage.
- nvim_open_win() floating windows can show a 'statusline'. Plugins can use `style='minimal'` or `:setlocal statusline=` to hide the statusline.
- nvim_win_set_config() can move floating-windows to other tabpages.
- EXPERIMENTAL: nvim__exec_lua_fast() allows remote API clients to execute Lua while Nvim is blocking for input. api-fast
- Decoration provider gained an `on_range` callback (deprecates `on_line`).
- vim.secure.trust() accepts `path` for the `allow` action.
- nvim_get_chan_info() includes `exitcode` field for :terminal buffers.
- nvim_set_hl() supports updating specified attributes only.

BUILD

- EXPERIMENTAL: Zig-based build is available as an alternative to CMake. It is currently limited in functionality, and CMake remains the recommended option for the time being.
- Nvim can be built without Unibilium (terminfo implementation), in which case the user's terminfo database won't be loaded and only internal definitions for the most common terminals are used:

```
make distclean && make CMAKE_EXTRA_FLAGS="-DENABLE_UNIBILIUM=0" DEPS_CMAKE_FLAGS="-DUSE_BUNDLED_UNIBILIUM=0"
```

- On Windows, `tee.exe` is included with `nvim.exe` by default so that commands like :make, :grep work out of the box.

DEFAULTS

- 'diffopt' default value now includes "indent-heuristic" and "inline:char".
- 'statusline' default is exposed as a statusline expression (previously it was implemented as an internal C routine).
- Default 'statusline' shows:
  - vim.diagnostic.status()
  - vim.ui.progress_status()
  - :terminal exit code
- Project-local configuration ('exrc') is also loaded from parent directories. Unset 'exrc' to stop further search.
- Mappings:
  - grt in Normal mode maps to vim.lsp.buf.type_definition()
  - grx in Normal mode maps to vim.lsp.codelens.run()
- 'shada' default now excludes "/tmp/" and "/private/" paths to reduce clutter in :oldfiles.
- Enabled treesitter highlighting for Markdown files.

DIAGNOSTICS

- vim.diagnostic.setloclist() and vim.diagnostic.setqflist() now support a `format` function to modify (or filter) diagnostics before being set in the location/quickfix list.
- vim.diagnostic.get() now accepts an `enabled` filter to only return enabled or disabled diagnostics.
- vim.diagnostic.status() returns a status description of current buffer diagnostics.
- vim.diagnostic.fromqflist() accepts `opts.merge_lines` to merge multiline compiler messages.

EDITOR

- :iput works like :put but adjusts indent.
- :retab accepts new optional parameter -indentonly to only change leading whitespace in indented lines.
- :uniq deduplicates text in the current buffer.
- omnicompletion is available when editing help buffers. ft-help-omni
- :help! has DWIM ("Do What I Mean") behavior: it tries to guess the help tag at cursor. In help buffers, 'keywordprg' defaults to ":help!". For example, try "K" anywhere in this code:

```
local v = vim.version.parse(vim.system({'foo'}):wait().stdout)
```

- Setting "'0" in 'shada' prevents storing the jumplist in the shada file.
- 'shada' now correctly respects "/0" and "f0".
- prompt-buffer supports multiline input/paste, undo/redo, and o/O normal commands.
- 'wildchar' now enables completion in search contexts using /, ?, :g, :v and :vimgrep commands.
- Security: 'exrc' no longer shows "(a)llow". Instead you must "(v)iew", then run `:trust` (or `:trust [file]`, but that has a TOCTOU risk).
- gx in help buffers opens the online documentation for the tag at cursor.
- :source with a range in non-Lua files (e.g., vimdoc) now detects Lua codeblocks via treesitter and executes them as Lua instead of Vimscript. (Or use `:{range}lua` to skip the detection.)
- :wall with ++p auto-creates missing parent directories.

EVENTS

- In the ui-protocol, message kind `empty` is emitted for empty messages (e.g. `:echo ""`).
- CmdlineLeave sets v:char to the character that stops the Cmdline mode.
- CmdlineLeavePre triggered before preparing to leave the command line.
- New append, `id` and `trigger` parameter for ui-messages `msg_show` event.
- 'rulerformat' is emitted as `msg_ruler` when not part of the statusline.
- Creating or updating a progress message with nvim_echo() triggers a Progress event.
- MarkSet is triggered after a mark is set by the user (currently doesn't support implicit marks like '[or '<, ...).

- SessionLoadPre is triggered before loading a Session file.
- TabClosedPre is triggered before closing a tabpage.
- TermRequest event gained a `terminator` parameter.

HIGHLIGHTS

- hl-DiffTextAdd highlights added text within a changed line.
- hl-OkMsg hl-StderrMsg hl-StdoutMsg
- hl-SnippetTabstopActive highlights the currently active tabstop.
- hl-PmenuBorder hl-PmenuShadow hl-PmenuShadowThrough see 'pumborder'.
- nvim_set_hl() and nvim_get_hl() support the SGR attributes "dim", "blink", "conceal", and "overline".

LSP

- lsp-completion:
  - vim.lsp.completion.enable() gained a `cmp` option for custom ordering.
  - Supports colored symbol preview for color items.
  - Shows a preview ("completionItem/resolve") if 'completeopt' has "popup".
  - Support for `textDocument/inlineCompletion` lsp-inline_completion https://microsoft.github.io/language-server-protocol/specifications/lsp/3.18/specification/#textDocument_inlineCompletion See lsp-inline_completion for quickstart instructions.
- :lsp can be used to interactively manage LSP clients.
- vim.lsp.ClientConfig gained `workspace_required`.
- You can control the priority of vim.lsp.Config `root_markers`.
- LSP capabilities:
  - `textDocument/codeLens` lsp-codelens was reimplemented. https://microsoft.github.io/language-server-protocol/specifications/lsp/3.18/specification/#textDocument_codeLens
  - `textDocument/colorPresentation` lsp-document_color https://microsoft.github.io/language-server-protocol/specification/#textDocument_colorPresentation
  - `textDocument/diagnostic`
  - `textDocument/documentColor` lsp-document_color https://microsoft.github.io/language-server-protocol/specification/#textDocument_documentColor
  - `textDocument/documentLink`: gx opens "documentLink" items at cursor.
  - `textDocument/inlineCompletion`
  - `textDocument/linkedEditingRange` lsp-linked_editing_range https://microsoft.github.io/language-server-protocol/specification/#textDocument_linkedEditingRange
  - `textDocument/onTypeFormatting` lsp-on_type_formatting https://microsoft.github.io/language-server-protocol/specification/#textDocument_onTypeFormatting
  - `textDocument/selectionRange` Incremental selection. v_an selects outwards, v_in selects inwards.
  - `textDocument/semanticTokens/range`
  - `workspace/codeLens/refresh` https://microsoft.github.io/language-server-protocol/specifications/lsp/3.17/specification/#codeLens_refresh
  - `workspace/diagnostic/refresh` https://microsoft.github.io/language-server-protocol/specification/#diagnostic_refresh
  - `workspace/diagnostic` vim.lsp.buf.workspace_diagnostics() https://microsoft.github.io/language-server-protocol/specifications/specification-current/#workspace_dagnostics
- Support for dynamic registration:
  - `textDocument/diagnostic`
- The `textDocument/diagnostic` request now includes the previous id in its parameters.
- vim.lsp.enable() start/stops clients as necessary and detaches non-applicable LSP clients.
- vim.lsp.is_enabled() checks if a LSP config is enabled (without "resolving" it).
- vim.lsp.get_configs() gets all LSP configs matching an optional filter.
- Support for multiline semantic tokens.
- Support for the `disabled` field on code actions.
- The function form of `cmd` in a vim.lsp.Config or vim.lsp.ClientConfig receives the resolved config as the second arg: `cmd(dispatchers, config)`.
- Support for annotated text edits.
- `:checkhealth vim.lsp` is now available to check which buffers the active LSP features are attached to.
- LSP `DiagnosticRelatedInformation` is now shown in vim.diagnostic.open_float(). It is read from the LSP diagnostic object stored in the `user_data` field.
- When inside the float created by vim.diagnostic.open_float() and the cursor is on a line with `DiagnosticRelatedInformation`, gf can be used to jump to the problematic location.
- Support for related documents in pull diagnostics: https://microsoft.github.io/language-server-protocol/specifications/specification-current/#relatedFullDocumentDiagnosticReport
- vim.lsp.buf.signature_help() supports "noActiveParameterSupport".
- The filter option of vim.lsp.buf.code_action() now receives the client ID as an argument.
- vim.lsp.ClientConfig `exit_timeout` decides the time waited before "stop" escalates to "force-stop" for vim.lsp.enable(), Client:stop(), and during Nvim shutdown.
  - `exit_timeout` graduated from "experimental" `flags.exit_timeout` to a top-level field. Defaults to `false`.
- Client:stop() accepts `force` as an integer, which is treated as the time to wait before before stop escalates to force-stop.
- vim.lsp.buf.rename() now highlights the symbol being renamed using the hl-LspReferenceTarget highlight group.
- Code lenses now display as virtual lines

LUA

- vim.net.request() can fetch/download HTTP content.
- vim.wait() returns the callback results.
- Lua type annotations for `vim.uv`.
- vim.hl.range() now allows multiple timed highlights.

- vim.tbl_extend(), vim.tbl_deep_extend() `behavior` argument can be a function.
- vim.fs.root() can define "equal priority" via nested lists.
- vim.fs.ext() returns the last extension of a file.
- vim.version.range() can output human-readable string via tostring().
- vim.version.intersect() computes intersection of two version ranges.
- Iter:take() and Iter:skip() now optionally accept predicates.
- Iter:peek() now works for all iterator types, not just list-iterator.
- vim.list.unique() and Iter:unique() to deduplicate lists and iterators, respectively.
- vim.list.bisect() performs binary search.
- vim.json.encode() `indent` option performs pretty-formatting.
- vim.json.encode() `sort_keys` option sorts by key.
- vim.json.decode() `skip_comments` option allows comments in JSON data.
- EXPERIMENTAL: vim.pos, vim.range provide Position/Range abstraction.

OPTIONS

- 'autocomplete' enables ins-autocompletion.
- 'autowriteall' writes all buffers upon receiving `SIGHUP`, `SIGQUIT` or `SIGTSTP`.
- 'chistory' and 'lhistory' set size of the quickfix-stack.
- 'complete' new flags:
  - "F{func}" complete using given function
  - "F" complete using 'completefunc'
  - "o" complete using 'omnifunc'
- 'complete' allows limiting matches for sources using "{flag}^<limit>".
- 'completeopt' flag "nearest" sorts completion results by distance to cursor.
- 'diffanchors' specifies addresses to anchor a diff.
- 'diffopt' `inline:` configures diff highlighting for changes within a line.
- 'diffopt' with `inline:word` now automatically merges adjacent diff blocks separated by gaps and punctuation by 5 bytes to improve readability.
- 'fillchars' has new flag "foldinner".
- 'fsync' and 'grepformat' are now global-local options.
- 'listchars' has new flag "leadtab".
- 'jumpoptions' flag "view" now applies when popping the tagstack.
- 'maxsearchcount' sets maximum value for searchcount() and defaults to 999.
- 'pummaxwidth' sets maximum width for the completion popup menu.
- 'winborder' "bold" style, custom border style.
- 'busy' sets a buffer "busy" status. Indicated in the default statusline.
- 'pumborder' adds a border to the popup menu.
- g:clipboard accepts a string name to force any builtin clipboard tool.
- g:clipboard autodetection selects tmux only when running inside tmux.
- 'statusline' allows "stacking" highlight groups (groups inherit from previous highlight attributes)
- 'messagesopt' "progress:c" flag controls whether progress messages are shown in the cmdline message area.
- Improved :set+=, :set^= and :set-= handling of comma-separated "key:value" pairs (e.g. 'listchars', 'fillchars', 'diffopt').

PERFORMANCE

- vim.glob.to_lpeg() uses a new LPeg-based implementation (Peglob) that provides ~50% speedup for complex patterns. The implementation restores support for nested braces and follows LSP 3.17 specification with additional constraints for improved correctness and resistance to backtracking edge cases.
- i_CTRL-R inserts named/clipboard registers literally, 10x speedup.
- LSP `textDocument/semanticTokens/range` is supported, which requests tokens for the viewport (visible screen) only.
- :packadd doesn't invalidate the cached Lua package path. Instead the cache gets updated in place. This might make a big startuptime difference for certain init.lua patterns where multiple :packadd or vim.pack.add() calls are interspersed with other code.

PLUGINS

- Built-in plugin manager: vim.pack
- :DiffTool compares directories (and files).
- :Undotree lets you visually navigate the undo-tree.
- Customize :checkhealth by handling a `FileType checkhealth` event. health-usage
- Simplify Python provider setup to a single step: `uv tool install pynvim` Nvim will detect the plugin's location without user configuration, even if unrelated Python virtual environments are activated. provider-python
- :checkhealth now checks for an available vim.ui.open() handler.
- spellfile.vim : Replaced by package-spellfile.

STARTUP

- v:argf provides file arguments given at startup.
- Nvim shows a warning if the log file path is inaccessible.

TERMINAL

- nvim_open_term() can be called with a non-empty buffer. The buffer contents are piped to the PTY and displayed as terminal output.
- CSI 3 J (the sequence to clear terminal scrollback) is now supported.
- DEC private mode 2026 (synchronized output) is now supported. Applications running in :terminal can batch screen updates to avoid tearing.
- A suspended PTY process is now indicated by "[Process suspended]" at the bottom-left of the buffer and can be resumed by pressing a key.
- On terminal exit, "[Process exited]" is shown as virtual text (instead of modifying buffer contents), and exit code is shown in statusline.

- You can disable "[Process exited]" entirely, see terminal-config.

TREESITTER

- Query:iter_captures() supports specifying starting and ending columns.
- :EditQuery command gained tab-completion, works with injected languages.
- LanguageTree:parse() now accepts a list of ranges.
- v_an v_in v_]n v_[n incremental selection of treesitter nodes.

TUI

- TermResponse now supports DA1 and APC query responses.
- Native progress bars are displayed for Progress events using the OSC 9;4 sequence.
- The TUI now renders the SGR dim (faint), blink, conceal, and overline attributes.

UI

- ui2 is a redesign of the core messages and commandline UI, which will replace the legacy message grid in the TUI.
  - Avoids "Press ENTER" interruptions.
  - Avoids delays from W10 "Changing a readonly file" and other warnings.
  - Highlights the cmdline as you type.
  - Provides the pager as a buffer + window.
  - Currently experimental. To enable it: `require('vim._core.ui2').enable()`
- :restart restarts Nvim and reattaches all UIs.
- :connect dynamically connects the current UI to the server at the given address.
- :checkhealth shows a summary in the header for every healthcheck.
- ui-multigrid provides composition information and absolute coordinates.
- Error messages are more concise:
  - "Error detected while processing:" changed to "Error in:".
  - "Error executing Lua:" changed to "Lua:".
- 'busy' status is shown in default statusline with symbol ◐
- Cursor shape indicates when it is behind an unfocused floating window.
- Improved LSP signature help rendering.
- Multigrid UIs can call nvim_input_mouse with grid 0 to let Nvim decide the grid.
- vim.ui.progress_status() returns a status description of currently running progress-messages.

VIMSCRIPT

- chdir() allows optionally specifying a scope argument.
- cmdcomplete_info() gets current cmdline completion info.
- getcompletiontype() gets command-line completion type for any string.
- has() gained two new system dependent feature flags, android and termux.
- prompt_getinput() gets current user-input in prompt-buffer.
- wildtrigger() triggers command-line expansion.
- v:vim_did_init is set after sourcing init.vim but before load-plugins.
- prompt_appendbuf() appends text to prompt-buffer.

CHANGED FEATURES

These existing features changed their behavior.

- 'pumblend' does not apply special attributes (bold, underline) from the background layer to the foreground layer.
- gv works in operator pending mode and does not abort.
- 'smartcase' applies to completion filtering.
- 'spellfile' location defaults to `stdpath("data")."/site/spell/"` instead of the first writable directory in 'runtimepath'.
- vim.version.range() doesn't exclude `to` if it is equal to `from`.
- $VIM and $VIMRUNTIME no longer check for Vim version-specific runtime directory `vim{number}` (e.g. `vim82`).
- 'scrollback' maximum value increased from 100000 to 1000000
- matchfuzzy() and matchfuzzypos() use an improved fuzzy matching algorithm (same as fzy).
- Windows: Paths like "\Windows" and "/Windows" are now considered to be absolute paths (to the current drive) and no longer relative.
- When 'shelltemp' is off, shell commands now use `pipe()` and not `socketpair()` for input and output. This matters mostly for Linux where some command lines using "/dev/stdin" and similar would break as these special files can be reopened when backed by pipes but not when backed by socket pairs.

REMOVED FEATURES

These deprecated features were removed.

- vim.treesitter.get_parser() instead of throwing an error `get_parser()` now always returns nil when it fails to create a parser.

DEPRECATIONS

See deprecated-0.12.

Notable changes since Nvim 0.8

BREAKING CHANGES

The following changes may require adaptations in user config or plugins.

- Cscope support is now removed (see cscope and nvim-removed):
  - Commands removed:
    - `:cscope`
    - `:lcscope`
    - `:scscope`
    - `:cstag`
  - Options removed:
    - `cscopepathcomp`
    - `cscopeprg`
    - `cscopequickfix`
    - `cscoperelative`
    - `cscopetag`
    - `cscopetagorder`
    - `cscopeverbose`
  - Eval functions removed:
    - `cscope_connection()`

Note: support for ctags remains with no plans to remove.

See https://github.com/neovim/neovim/pull/20545 for more information.

- `:hardcopy` is now removed (see hardcopy and nvim-removed):
  - Commands removed:
    - `:hardcopy`
  - Options removed:
    - `printdevice`
    - `printencoding`
    - `printexpr`
    - `printfont`
    - `printheader`
    - `printmbcharset`
- 'paste' option is now deprecated and 'pastetoggle' is removed. paste works automatically in GUI and terminal (TUI) Nvim. Just Paste It.™
- Changes to vim.treesitter.get_node_text():
  - It now returns `string`, as opposed to `string|string[]|nil`.
  - The `concat` option has been removed as it was not consistently applied.
  - Invalid ranges now cause an error instead of returning `nil`.
- `help` treesitter parser was renamed to `vimdoc`. The only user-visible change is that language-specific highlight groups need to be renamed from `@foo.help` to `@foo.vimdoc`.
- The default value of 'commentstring' is now empty instead of "/*%s*/".
- libiconv and intl are now required build dependencies.

NEW FEATURES

The following new APIs or features were added.

- Treesitter syntax highlighting for `help` files now supports highlighted code examples. To enable, create a `.config/nvim/ftplugin/help.lua` with the contents

```
vim.treesitter.start()
```

  - **Note:** Highlighted code examples are only available in the Nvim manual, not in help files taken from Vim. The treesitter `vimdoc` parser is also work in progress and not guaranteed to correctly highlight every help file in the wild.
- Added support for semantic token highlighting to the LSP client. This functionality is enabled by default when a client that supports this feature is attached to a buffer. Opt-out can be performed by deleting the `semanticTokensProvider` from the LSP client's `{server_capabilities}` in the `LspAttach` callback. See lsp-semantic-highlight for more information.
- vim.inspect_pos(), vim.show_pos() and :Inspect allow a user to get or show items at a given buffer position. Currently this includes treesitter captures, LSP semantic tokens, syntax groups and extmarks.
- vim.treesitter.inspect_tree() and :InspectTree opens a split window showing a text representation of the nodes in a language tree for the current buffer.
- 'statuscolumn' option to customize the area to the side of a window, normally containing the fold, sign and number columns. This new option follows the 'statusline' syntax and can be used to transform the line numbers, create mouse click callbacks for signs, introduce a custom margin or separator etc.
- vim.secure.trust(), :trust allows the user to manage files in trust database. vim.secure.read() reads a file and prompts the user if it should be trusted and, if so, returns the file's contents. Used by 'exrc'
- EditorConfig support is now builtin. This is enabled by default and happens automatically. To disable it, add the following to your config:

```
vim.g.editorconfig = false
```

- A new environment variable named NVIM_APPNAME enables configuring the directories where Nvim should find its configuration and state files. See `:help $NVIM_APPNAME` .
- Added support for running Lua scripts from shell using -l.

```
nvim -l foo.lua --arg1 --arg2
```

Also works with stdin:

```
echo "print(42)" | nvim -l -
```

- Added an omnifunc implementation for Lua, vim.lua_omnifunc()
- Added a new experimental vim.loader that byte-compiles and caches Lua files. To enable the new loader, add the following at the top of your init.lua:

```
vim.loader.enable()
```

- Added vim.version for parsing and comparing version strings conforming to the semver specification.
- When using Nvim inside tmux 3.2 or later, the default clipboard provider will now copy to the system clipboard. provider-clipboard
- 'showcmdloc' option to display the 'showcmd' information in the status line or tab line. A new %S statusline item is available to place the 'showcmd' text in a custom 'statusline'. Useful for when 'cmdheight' is set to 0.
- 'splitkeep' option to control the scroll behavior of horizontal splits.
- 'wildoptions' flag "fuzzy" enables fuzzy-matching during cmdline-completion.
- 'diffopt' now includes a `linematch` option to enable a second-stage diff on individual hunks to provide much more accurate diffs. This option is also available to vim.text.diff()

See https://github.com/neovim/neovim/pull/14537.

- --remote-ui option was added to connect to a remote instance and display in it in a TUI in the local terminal. This can be used run a headless nvim instance in the background and display its UI on demand, which previously only was possible using an external UI implementation.
- Added a vim.lsp.codelens.clear() function to clear codelenses.
- Added support for the `willSave` and `willSaveWaitUntil` capabilities to the LSP client. `willSaveWaitUntil` allows a server to modify a document before it gets saved. Example use-cases by language servers include removing unused imports, or formatting the file.
- Added preliminary support for the `workspace/didChangeWatchedFiles` capability to the LSP client to notify servers of file changes on disk. The feature is disabled by default and can be enabled by setting the `workspace.didChangeWatchedFiles.dynamicRegistration=true` capability.
- vim.diagnostic now supports LSP DiagnosticsTag. See: https://microsoft.github.io/language-server-protocol/specification/#diagnosticTag
- vim.diagnostic.is_disabled() checks if diagnostics are disabled in a given buffer or namespace.
- Treesitter captures can now be transformed by directives. This will allow more complicated dynamic language injections.
- vim.treesitter.get_node_text() now accepts a `metadata` option for writing custom directives using vim.treesitter.query.add_directive().
- vim.treesitter.language.add() replaces `vim.treesitter.language.require_language`.
- vim.treesitter.foldexpr() can be used for 'foldexpr' to use treesitter for folding.
- Expanded the TSNode API with:
  - TSNode:tree()
  - TSNode:has_changes()
  - TSNode:extra()
  - TSNode:equal()

Additionally TSNode:range() now takes an optional `{include_bytes}` argument.

- Treesitter injection queries now use the format described at https://tree-sitter.github.io/tree-sitter/3-syntax-highlighting.html#language-injection . Support for the previous format will be removed in a future release.
- Added nvim_get_hl() for getting highlight group definitions in a format compatible with nvim_set_hl().
- vim.filetype.get_option() to get the default option value for a specific filetype. This is a wrapper around nvim_get_option_value() with caching.
- `require'bit'` is now always available lua-bit

CHANGED FEATURES

The following changes to existing APIs or features add new behavior.

- 'exrc' now supports `.nvim.lua` file.
- 'exrc' is no longer marked deprecated.
- The TUI is changed to run in a separate process (previously, a separate thread was used). This is not supposed to be a visible change to the user, but might be the cause of subtle changes of behavior and bugs.

Previously, the TUI could be disabled as a build time feature (+tui/-tui), resulting in a nvim binary which only could be run headless or embedded in an external process. As of this version, TUI is always available.

- Vim's `has('gui_running')` is now supported as a way for plugins to check if a GUI (not the TUI) is attached to Nvim. has()
- msgsep is now always enabled even if 'display' doesn't contain the "msgsep" flag. It is no longer possible to scroll the whole screen when showing messages longer than 'cmdheight'.
- API calls now show more information about where an exception happened.
- The `win_viewport` UI event now contains information about virtual lines, meaning that smooth scrolling can now be implemented more consistently.
- The `:= {expr}` syntax can be used to evaluate a Lua expression, as a shorter form of `:lua ={expr}`. `:=` and `:[range]=` without argument are unchanged. However `:=#` and similar variants using ex-flags are no longer supported.
- Unsaved changes are now preserved rather than discarded when channel-stdio is closed.
- nvim_open_win() now accepts a relative `mouse` option to open a floating win relative to the mouse. Note that the mouse doesn't update frequently without setting `vim.o.mousemoveevent = true`
- nvim_eval_statusline() supports evaluating the 'statuscolumn' through a new `opts` field: `use_statuscol_lnum`.
- nvim_buf_get_extmarks() now accepts a `-1` `ns_id` to request extmarks from all namespaces and adds the namespace id to the details array. Other missing properties have been added to the details array and marks can be filtered by type.
- vim.diagnostic.open_float() (and therefore vim.diagnostic.config()) now accepts a `suffix` option which, by default, renders LSP error codes. Similarly, the `virtual_text` configuration in vim.diagnostic.config() now has a `suffix` option which does nothing by default.
- vim.fs.dir() now has a `opts` argument with a depth field to allow recursively searching a directory tree.
- vim.gsplit() supports all features of vim.split().

- :highlight now supports an additional attribute "altfont".
- :Man manpage viewer supports manpage names containing spaces.
- nvim_select_popupmenu_item() now supports cmdline-completion popup menu.
- nvim_list_uis() reports all ui-option fields.
- nvim_get_option_value() now has a `filetype` option so it can return the default option for a specific filetype.
- build: Several improvements were made to make the code generation scripts more deterministic, and a `LUA_GEN_PRG` build parameter has been introduced to allow for a workaround for some remaining reproducibility problems.

REMOVED FEATURES

The following deprecated functions or APIs were removed.

- `filetype.vim` is removed in favor of vim.filetype (Note that filetype logic and tests still align with Vim, so additions or changes need to be contributed there first.) See https://github.com/neovim/neovim/pull/20674.
- 'hkmap', 'hkmapp' and 'aleph' options were removed. Use 'keymap' option instead.
- LanguageTree:parse() no longer returns changed regions. Please use the `on_changedtree` callbacks instead.
- `vim.highlight.create()`, `vim.highlight.link()` were removed, use nvim_set_hl() instead.
- `require'health'` was removed. Use vim.health instead.

DEPRECATIONS

See deprecated-0.9.

Notable changes since Nvim 0.12

For changes in the previous release, see news-0.12.

BREAKING CHANGES IN HEAD OR EXPERIMENTAL news-breaking-dev

====== Remove this section before release. ======

The following changes to UNRELEASED features were made during the development cycle (Nvim HEAD, the "master" branch).

EVENTS

- todo

EXPERIMENTS

- todo

LSP

- todo

LUA

- vim.pos, vim.range always require the `buf` parameter.
- range.cursor() and range.to_cursor() are removed. Use range.mark() and range.to_mark() instead.
- pos.to_cursor() returns a `(row, col)` tuple instead of returning them as separate values.
- Renamed current_level param of vim.log.new().
- `vim.opt.{option}:get()` has improved structure for dict-like options. Some shapes changed:
  - "key:value" list options (e.g. 'diffopt', 'mousescroll') return a map `{ key = value }` instead of an array of `"key:value"` strings.
  - The `,,` literal-comma convention (e.g. 'isfname') is not reconstructed in the structured view; the raw string value is unchanged.

DIAGNOSTICS

- todo

OPTIONS

- When ui2 is enabled, since the ruler is no longer a left-aligned box of fixed width, there is no longer an inconsistent special handling of item groups in 'rulerformat' to configure that fixed width. An old-style left- aligned fixed-width ruler can now be achieved by using item groups exactly as they are documented, e.g. `%-20.20(...%)`.

TREESITTER

- todo

UI

- Healthchecks for vim.ui.img were moved to `:checkhealth vim.health`.
- ui2 messages pager no longer uses <CR> by default; use g< or set 'messagesopt' "pager", e.g. `:set messagesopt+=pager:<CR>`.
- ui2 `cfg.pager_char` and `cfg.msg.msg.timeout` were replaced by the 'messagesopt' items "pager" and "timeout".

VIMSCRIPT

- todo

BREAKING CHANGES news-breaking

These changes may require adaptations in your config or plugins.

API

- API results containing a Lua function reference (e.g. a "callback" reported by nvim_get_keymap() or nvim_get_autocmds(), or a "callback" option value) are serialized over RPC as a human-readable "<Lua …>" hint string, instead of nil.
- nvim_create_autocmd(), nvim_exec_autocmds() and nvim_clear_autocmds() no longer treat an empty non-nil pattern as nil.
- nvim_clear_autocmds() no longer treats an empty array event as nil.
- vim.o, vim.opt, and nvim_set_option_value() expand ~ and environment variables (expand-env).

DIAGNOSTICS

- `vim.diagnostic.Opts.Status.format` no longer accepts the table mapping from severity to text. Use `vim.diagnostic.Opts.Signs.text` instead.
- `current_line` property of vim.diagnostic.Opts.VirtualLines and vim.diagnostic.Opts.VirtualText is now applied on CursorHold event. Make sure your 'updatetime' is reasonable.

EDITOR

- Interactive Ex-mode (:exmode, `nvim -e`) is a persistent cmdwin. This is much more flexible and makes "Ex mode" more useful as a kind of "cmdline REPL", with the tradeoff of dropping some POSIX Ex-mode quirks.

    - mode() returns "n" or "i"; "cv" indicates -es (script mode) only.
    - Ex mode is entered with "1q:" or :exmode, not "gQ".
    - ":global/pat/visual" no longer switches to Normal mode per matching line.
- Non-interactive Ex-mode (-es, "script mode") executes stdin as Ex commands directly. It is a "script host", not "POSIX Ex mode".
    - Output ends with a final newline.
    - :visual is :edit: it does not switch to reading stdin as Normal-mode commands, and ":global/pat/visual" does not enter Normal mode per matching line.
    - Commands that wait for typed input (input(), getchar(), ...) stop Nvim at end-of-input instead of consuming the next stdin line.
    - An empty line is a no-op instead of advancing the cursor (or failing with E501 at end-of-file).
- On Windows, the trust db now stores paths with "/" slashes. This means the trust store will be reset (one time).
- `stdpath("log")` moved to `stdpath("state")/logs`.
- An operator on a target that creates a Visual selection ("cgn") does not change '< '>. gv
- cmdwin (q:, q/, q?, c_CTRL-F):
    - Only supports one "cmdline level", not "infinite recursion".
    - Expr-register (i_CTRL-R_=, c_CTRL-R_=) no longer supports opening cmdwin via c_CTRL-F.
- Behavior of :restart changed. Use "!" (:restart!) to get the old behavior.
    - ZR now performs :restart. Add a count to change the behavior.
- ins-repeat replays the full Insert session, including cursor-moves. Undo and quote. still restart at each cursor-move. Use i_CTRL-O to get the old behavior:

```
inoremap <Left>  <C-o><Left>
inoremap <Right> <C-o><Right>
```

- visual-repeat is "semantic" instead of "fixed-size". See visual-fixed-size if you prefer Vim's "fixed-size" Visual-repeat.
- :diffget, :diffput (do, dp) can be . repeated.
- Q adds a multicursor instead of replaying the last recorded register. To get the old behavior:

```
vim.keymap.set('n', 'Q', function()
  local reg = vim.fn.reg_recorded()
  return reg == '' and '' or ('@' .. reg)
end, { expr = true })
```

EVENTS

- vim.on_key() callbacks are not invoked for keys consumed by getchar().
- BufModifiedSet has been removed. Use the OptionSet event with pattern "modified" instead.
- ui-messages `msg_show.bufwrite` and `msg_show.completion` messages are now `msg_show.progress` events.

LSP

- `vim.lsp.ClientConfig.cmd` given as a string array now uses `vim.lsp.ClientConfig.root_dir` as its default process working directory.
- `client.attached_buffers[buf]` now stores `languageId` string (was boolean).

LUA

- "standalone" Lua interpreter mode `nvim -ll` was removed. Use -l script mode instead.
- vim.opt no longer supports chaining multiple infix operators (e.g. `vim.opt.wildignore + '*.o' + '*.obj'`). Instead, use tables: `vim.opt.wildignore + {'*.o', '*.obj'}`

OPTIONS

- The 'statusline' %= item is no longer ignored in item groups. It applies to the containing item group and its `minwid`. An %< item inside an item group now only applies to the containing group and its `maxwid`. Therefore, multiple %< can now be effective. The default truncation of item groups is now at the first contained item. To restore the previous truncation from the left, add a %< to the start. The same applies to 'rulerformat', 'statuscolumn', 'tabline', 'winbar', 'titlestring', and 'iconstring'.
- 'rulerformat' can no longer be set empty, the new default expression will be restored instead.

PLUGINS

- todo

TREESITTER

- todo

UI

- The bottom right cell of the screen is no longer left empty when the ruler is shown. This was originally intended to prevent unwanted scrolling on quirky terminals.

VIMSCRIPT

- Removed: ctxget(), ctxpop(), ctxpush(), ctxset(), ctxsize(). Use nvim_get_context() and nvim_load_context() instead.

NEW FEATURES

news-features

The following new features were added.

API

- nvim_win_resize() resizes a window with a specified anchor edge. nvim_win_set_height() and nvim_win_set_width() are now deprecated.
- api-contract treats `opts` and any parameters thereafter, as optional (equivalent to passing an empty dict). Clients may omit such optional parameters.
  - The Lua vim.api bridge is also a "client" and thus may omit `opts` and any following parameters:

    ```
    -- Before:
    vim.print(vim.api.nvim_get_mark('A', {}))
    -- After:
    vim.print(vim.api.nvim_get_mark('A'))
    ```

- nvim_buf_call() and nvim_win_call() now preserve multiple return values.
- nvim_del_keymap(), nvim_buf_del_keymap() and vim.keymap.del() can match only `{lhs}`, not `{rhs}`, with `opts.lhs=true`.
- nvim_set_hl() supports "font" key.
- nvim_open_win() `zindex` controls whether the UI will use a dimmed cursor shape when an unfocused float is on top of the cursor.
- nvim_echo() distinguishes zero percent from omitted percent for Progress events.
- nvim_create_user_command() accepts `desc` for Vimscript commands.
- Support for tabpage-local options ('cmdheight'):
  - gettabvar()
  - gettabwinvar()
  - nvim_get_option_info2()
  - nvim_get_option_value()
  - nvim_set_option_value()
- nvim_buf_set_extmark() `virt_lines_overflow` accepts "wrap" to enable wrapping onto extra rows and "auto" which enables horizontal scrolling when 'nowrap' is set and wrapping when 'wrap' is set.
- nvim_buf_set_extmark() `virt_lines` can extend the last `hl` in each `virt_line` till the end of the line.
- nvim_set_option_value() accepts a new `operation` field to modify the existing option value.
- nvim_set_option_value() returns the new option value.
- nvim_create_autocmd() is now api-fast, so it can be called from a fast event context (e.g. vim.uv callbacks).
- nvim_create_autocmd() callback event-args provide `win`.
- nvim_chan_set() sets channel properties. With `detach=false`, any RPC channel can enable Nvim "self-exit on channel-close" behavior.

BUILD

- Building using "zig build" requires zig 0.16.x.
- zig build: "-Dcross" option was removed. Often cross-compilation is now detected, so e.g. from a linux host:

  ```
  zig build -Dtarget=aarch64-macos
  ```

  will automatically compile a host Lua for use during build.
- zig build: The new "-Dhost={target_string}" option can be used to override the used host. Use "-Dhost=native" to force cross-compiling or "-Dhost=" (empty string) to assume that target binaries can run on the host during the build process (e.g. if target is x86 on a x86_64 system, or if emulation set up with binfmt or similar).
- zig build: Nvim can now be built to produce a WebAssembly binary via "-Dtarget=wasm32-emscripten", which can run inside a web browser. A basic browser-based demo for running it is also included. Still very experimental.

DEFAULTS

- 'rulerformat' default is exposed as a statusline expression (previously it was implemented as an internal C routine).

DIAGNOSTICS

- vim.diagnostic.status() uses the severity names defined by the `signs` field of vim.diagnostic.config(), if any.
- `virtual_lines.overflow` in vim.diagnostic.config() controls how virtual lines wider than the window are displayed.

EDITOR

- Multiple cursors (multicursor): edit in many places at once.
  - Toggle cursors with Q, <C-LeftMouse>, or via API (the "nvim.multicursor" extmarks namespace).
  - Toggle "follow mode" with g=.
  - Clear cursors with CTRL-L, restore them with gQ.
  - zq places a cursor at all targets of a motion. E.g. "zqgn" places at every match (and "gv" selects the matches), "Vzqw" places at every Visual-selected word.
- :bcd sets a buffer-local directory. getcwd() and haslocaldir() take `bufnr` as a third parameter.
- :lcd! :tcd! :bcd! unsets the directory of that scope.
- :command-completion-customlist can return a list of dictionaries with kind/menu/info/abbr for the popup menu.
- cmdwin (q:, q/, q?, c_CTRL-F) is implemented as a "normal" buffer+window instead of a nested-state modal loop:
  - You can create/navigate windows/tabpages while cmdwin is active. Chaos!
  - 'inccommand' works in cmdwin!
  - API calls (e.g. nvim_buf_delete()) that previously failed with "E11: Invalid in command-line window" while cmdwin was open, now work normally. Async plugins no longer need special CmdwinLeave workarounds.
  - The cmdwin-char is shown via 'statuscolumn'.
- gf and <cfile> support `file://…` URIs.
- :help files render tables (example: api-types).
  - Spec: https://github.com/neovim/tree-sitter-vimdoc#tables
- :help documentation is available as PDF via: https://neovim.io/doc/user/nvim-help.pdf
- :log opens log files.
- :marks can list extmarks for a given namespace.

- :marks gained tab-completion.
- :restart saves/restores the current session (window layout, buffers, …).
  - :restart! (with a bang "!") does not save/restore the session.
- ZR restarts Nvim (:restart).
- :detach with range "%" detaches all UIs except the current one.
- :detach! (with bang "!") marks the current UI as detachable: Nvim will continue running if the UI disconnects unexpectedly (e.g. if you accidentally close your terminal, ssh connection lost, etc.). Use :connect to reattach.
- :uptime displays uptime.
- :packupdate and :packdel for managing vim.pack.
- 'scrollback' is now also valid in prompt-buffer buffers to limit the number of history lines kept above the prompt.
- v_al and v_il text objects select the whole buffer and the current line without leading or trailing white space.
- 'autoread' uses file system watchers to detect external changes in real-time, instead of only on FocusGained or :checktime.
- During complete()-triggered completion, CTRL-N and CTRL-P are now subject to insert-mode mappings.
- undo restores the cursor to its original position ("diw", "atest<Esc>", "d^", …), instead of jumping to the start of the changed text.
- undo no longer restores the old (wrong) position of a mark that you moved (m, :mark) later. The mark shifts with the text it was moved to, the same as a mark the change never touched.
- Multibyte characters, translated by 'langmap', now invoke correct mappings. Example:

```
set langmap=ő]
```

  Typing őő in Normal-mode now invokes a mapping bound to]].
- New complete-items field "commit_chars": characters that accept the selected completion item when typed.

EVENTS

- :delmarks now triggers the MarkSet autocommand with line==col==0, same as nvim_buf_del_mark()
- ChanClose is triggered after a channel is closed, before it is removed.
- CmdAtom fires after each atomic user action (motion, mapping, operator, insert session, visual, Ex command, …).
- SessionWritePre event emits just before :mksession.
- TextPutPre and TextPutPost are triggered before/after putting text.
- TabMoved is triggered when tabs are reordered.
- DirReadPost is triggered after each dir listing is rendered, so it can be sorted or filtered. See dir-render.

HIGHLIGHTS

- Dimmed for text that should be de-emphasized.
- vim.hl.hl_op() highlights text regions for TextYankPost and TextPutPost events. It replaces the now deprecated `vim.hl.on_yank()`.

LSP

- LSP capabilities:
  - Completion supports `CompletionItem.preselect` if 'completeopt' has "preselect". https://microsoft.github.io/language-server-protocol/specification/#completionClientCapabilities
  - `textDocument/foldingRange` vim.lsp.foldtext() highlights collapsed text. https://microsoft.github.io/language-server-protocol/specification/#textDocument_foldingRange
  - Completion supports `CompletionList.applyKind`: a server can ask for `commitCharacters` and `data` from `itemDefaults` to be merged with the item's own values instead of replacing them. https://microsoft.github.io/language-server-protocol/specification/#completionItemApplyKinds
  - Completion supports a `completionProvider` registered with `client/registerCapability` instead of declared at `initialize`. Nvim does not advertise `completion.dynamicRegistration` by default; set it in vim.lsp.Config `capabilities` to opt in. https://microsoft.github.io/language-server-protocol/specification/#client_registerCapability
- `:checkhealth vim.lsp` highlights the "current buffer".
- vim.lsp.buf.declaration(), vim.lsp.buf.definition(), vim.lsp.buf.type_definition(), and vim.lsp.buf.implementation() now follows 'switchbuf'.
- vim.lsp.buf.declaration(), vim.lsp.buf.definition(), vim.lsp.buf.type_definition(), and vim.lsp.buf.implementation() now supports passing arbitrary positions.
- Support for nested snippets.
- lsp-completion supports `commitCharacters`: typing a commit character while a completion item is selected accepts the item as with complete_CTRL-Y, then inserts the character. Previously `commitCharacters` had no effect.
- The `reuse_client` predicate now passes the target buffer. See vim.lsp.Config and vim.lsp.start()
- vim.lsp.formatexpr() now falls back to `textDocument/formatting` if the whole buffer is being formatted and the language server doesn't support `textDocument/rangeFormatting`.
- vim.lsp.buf.format() respects an explicit `timeout_ms` with `async=true`. The timeout applies per client. Async requests have no timeout when the option is omitted.
- Support for `workspace/foldingRange/refresh`: https://microsoft.github.io/language-server-protocol/specifications/lsp/3.18/specification/#workspace_foldingRange_refresh
- vim.lsp.completion.get() accepts a `client_id` to request from only the given clients.

LUA

- lua-async: `vim.async` provides structured concurrency primitives for Lua code, including task handles, await helpers, cooperative cancellation, completion-order iteration, and semaphores.
- vim.ui.img can display images. Use `:checkhealth vim.health` to confirm your terminal supports it.
- vim.net.request() can specify custom headers by passing `opts.headers`.
- vim.net.request() can now accept `method` param overload for multiple HTTP methods.
- writefile() treats Lua and RPC strings as Blob, so it can be used to write binary data.
- vim.fs.abspath() gained `cwd` and `plain` parameters.
- vim.fs.dir() with `opts.err=true`, reports errors. An inaccessible root dir yields a single (name, nil, err) item.
- vim.fs.dir() gained a `plain` parameter.

- vim.fs.find() returns a list of errors as its second return value.
- vim.fs.mkdir() creates directories, including parent directories with `opts.parents=true`.
- vim.fs.slug() generates a filesystem-safe file name from an arbitrary identity string, with an optional length bound.
- vim.filetype.inspect() returns a copy of the internal tables used for filetype detection.
- Added `__eq` metamethod to vim.VersionRange. 2 distinct but representing the same range instances now compare equal.
- Documentation for vim.fn now points to preferred Lua alternatives when available.
- vim.list.unique() and vim.list.bisect() now support passing a string as a shorthand of a key
- vim.isnil() tests if a value is `nil` or vim.NIL.
- vim.nonnil() returns the first argument which is not nil.
- vim.npcall() calls the function `fn` in protected-mode like pcall(), but returns `nil` on error.
- vim.pos can now convert between positions and buffer offsets.
- vim.pos and vim.range can now convert between mark positions.
- vim.pos.cursor() without arguments returns the cursor position of the current window.
- vim.ui.input() now allows setting input scope.
- vim.log provides a logging interface.
- vim.pack.get() output includes revision of a pending update.
- vim.pack.get() can fetch new updates before computing the output.
- vim.pack supports vim.pack-manifest of plugins.
- vim.o now accepts table style values for assignment.
- vim.keycode() returns structured info as return value 2.
- Iter:count() counts items in the iterator.

OPTIONS

- Lua functions/closures can be assigned to "func" and "expr" options: option-value-function (e.g. `vim.o.operatorfunc`), expr-option-function (e.g. `vim.wo.foldexpr`, `vim.bo.indentexpr`). Reading such an option:
  - ...from Lua, gets the function itself.
  - ...from Vimscript/RPC, gets a human-readable "<Lua …>" hint string.
- 'ttyfast' can be disabled during startup by setting $NVIM_NOTTYFAST.
- 'scrolloffpad' allows vertically centering cursor at the end of file.
- 'shortmess' flag shm-u silences undo/redo messages.
- 'statusline' supports stl-%0{ to insert the expression result verbatim. The %= item is supported within item groups to separate alignment sections within the containing group until its `minwid` is reached. The truncation of an item group to its `maxwid` can be controlled with the %< item. The new %#(...%#) item denotes a highlight scope. The same applies to 'rulerformat', 'statuscolumn', 'tabline', 'winbar', 'titlestring', and 'iconstring'.
- 'winpinned' prevents window from closing unless specifically targeted.
- 'packlockfile' sets the path used for vim.pack-lockfile.
- 'previewpopup' decides how the preview window is displayed.
- 'messagesopt' items "pager" and "timeout" configure the ui2 message pager key and how long a message stays in the message window.

PERFORMANCE

- LSP shares identical file watcher registrations, reducing startup work in large workspaces.
- treesitter-highlight performance on large injection-heavy files improves by 50% to 100% by reusing edited child-tree ranges.
- Nvim architecture allows pure-Lua implementations of some `vim.fn` functions, which skips the Vimscript <=> Lua "bridge" (no data conversion/marshalling) entirely, if the `vim.fn` function is called from Lua.
- Internal LSP data is cleared using `table.clear`, which reduces GC and memory reallocation during each data reset.
- RPC client avoids string allocations when parsing Content-Length messages.
- LSP: "overscan" semantic_token range requests to avoid flicker.
- vim.hl.range() and vim.hl.hl_op() are faster for large characterwise and linewise regions.
- The display of multibyte text with grapheme clusters has been optimized, by calculating byte length and cell width of clusters in a single loop.

PLUGINS

- The zip plugin is now zip, a read-only archive browser built on dir. To use the legacy plugin instead:

```
:packadd old-zip
```

- provider: add bun support for Node.js plugins

STARTUP

- --embed with --listen waits for a UI on the listen address if stdin is not a pipe (e.g. tty or /dev/null), instead of exiting.

TERMINAL

- todo

TREESITTER

- vim.treesitter.get_captures() returns highlight captures at a given position, on a whole line, or overlapping a range. It replaces vim.treesitter.get_captures_at_pos().
- v_]N v_[N expand selection to sibling treesitter node.
- treesitter-highlight-conceal can be removed by adding a `@noconceal` capture.
- vim.treesitter.select() starts or adjusts a visual selection at cursor, based on tree nodes.
- The `diff` treesitter parser is bundled.

TUI

- The TUI will re-query the terminal's background color when resuming from a suspended state, and Nvim will update 'background' accordingly.
- User can override the builtin "terminfo" via $NVIM_TERMDEFS. This is similar to Vim's t_xx options.

UI

- :checkhealth shows filewatcher info in the Performance section.
- Floating window border highlights (hl-FloatBorder, hl-FloatTitle, hl-FloatFooter) combine with the window-local hl-Normal background instead of falling back to the global background.
- These builtin "picker" menus delegate to vim.ui.select():
  - :browse oldfiles
  - :recover
  - :tselect
  - z= (spell suggest)
- The ui2 dialog window scrolls with the mouse wheel, by 'mousescroll' lines.
- The ui2 `[+x]` "spill" indicator is highlighted with hl-MoreMsg.

VIMSCRIPT

- `fnamemodify(':h')` preserves logical roots for more path formats.
- v:exitreason is set before QuitPre.
- v:startreason indicates whether Nvim started normally or by :restart.
- v:starttime is the process start time (nanoseconds since UNIX epoch).
- v:useractive indicates user activity.
- serverlist() with `info=true` returns details for each server (own + peers).
- These Vimscript functions may be called from api-fast context (e.g. vim.uv timer/handle callbacks): keytrans(), char2nr(), nr2char(), str2list(), strpart(), strcharpart(), strgetchar(), strchars(), strcharlen(), strlen(), strdisplaywidth(), byteidx(), charidx(), utf16idx(), tr(), trim().

CHANGED FEATURES news-changed

These existing features changed their behavior.

- Environment variable name (`$NAME`) validity is no longer controlled by 'isident'.
- `nvim_exec_autocmds({buf=…})` runs in the context of the target buffer.
- SessionLoadPost is no longer included in views saved by :mkview.
- OptionSet is no longer triggered during startup by automatic 'background' detection.
- SessionWritePre and SessionWritePost are no longer triggered by :mkview, :mkvimrc, or :mkexrc.
- Editing a local directory now shows its contents in a `filetype=directory` buffer. See dir.
- :Open with no arguments uses the current file.
- The "buffer" key was renamed to "buf" in these functions (but the old name "buffer" is still accepted, for backwards compatibility):
  - nvim_clear_autocmds()
  - nvim_create_autocmd()
  - nvim_exec_autocmds()
  - nvim_get_autocmds()
- vim.keymap.set() and vim.keymap.del() accept a list of strings for `lhs`.
- 'statuscolumn' click function labels can be different across rows. v:virtnum and v:lnum are available during the click function callback.
- Markdown inline highlighting now conceals the backslash in backslash escapes.
- Markdown inline backslash escapes and hard line breaks no longer use the `@string.escape` capture.
- vim.lsp.util.open_floating_preview() windows (e.g. vim.lsp.buf.hover()) converted to normal windows (e.g. with CTRL-W_H) are no longer closed automatically.
- vim.fs.normalize() `opts.expand_env=false` key was renamed to `opts.plain=true` and now does not expand leading tildes ("~") in addition to environment variables ("expand_env" is still accepted, for backwards compatibility).
- :helptags finds help tags with the "vimdoc" treesitter parser (and thus requires it to be installed).
- `:helptags ALL` reports E152 for "doc" directories it cannot write, instead of silently skipping them.
- The highlighting groups hl-CursorLineFold and hl-CursorLineSign are always used when 'cursorline' is set.
- vim.lsp.util.apply_text_edits() accepts `opts.keep_cursor`, to hold the cursor on the text it is on while edits move around it.
- 'tagfunc' is now also used for :tag completion.
- Some character clusters are restored to occupy two cells like they did prior to Nvim 0.11. These include Thai syllables like □□□ and half-width Katakana with voicing marks □□. The TUI renders these in a safe way which also supports terminals which consider these to be single-width.
- in script mode -l, print() now behaves more similar to standalone lua. Printing is done to stdout, and empty lines are not stripped. No translation of special characters is done, so escape sequences can be used when printing to a terminal.
- It is no longer allowed to change the window layout during a DiffUpdated autocommand.

REMOVED FEATURES news-removed

These deprecated features were removed.

- Vimscript functions ctxget(), ctxpop(), ctxpush(), ctxset(), ctxsize() and the "context stack". Use nvim_get_context() and nvim_load_context() with a script-owned list instead.
- vim.lsp.buf.declaration(), vim.lsp.buf.definition(), vim.lsp.buf.type_definition(), and vim.lsp.buf.implementation() no longer accept the `reuse_win` option.

DEPRECATIONS

news-deprecations

See deprecated-0.13.

Nvim neovim nvim-intro

Nvim is based on Vim by Bram Moolenaar. Nvim is emphatically a fork of Vim, not a clone: compatibility with Vim (especially editor and Vimscript features, except Vim9script) is maintained where possible. See vim-differences for the complete reference.

- If you already use Vim, see nvim-from-vim for a quickstart.
- If you have never used Vim or Nvim before, see below.

What now? nvim-quickstart

To learn how to use Vim in 30 minutes, try the tutorial:

```
:Tutor<Enter>
```

Or watch this 10-minute video: https://youtu.be/TQn2hJeHQbM .

config-example example-init To customize Nvim, you will need a config file. Create your init.lua by copying the "example_init.lua" file:

```
:exe 'edit' stdpath('config') .. '/init.lua'
:read $VIMRUNTIME/example_init.lua
:write ++p
:restart
```

See lua-guide for practical notes on using Lua to configure Nvim.

"IDE" features in Nvim are provided by LSP.

If you are just trying out Nvim for a few minutes, and want to see the extremes of what it can do, try one of these popular "extension packs" or "distributions" (**Note:** Nvim is not affiliated with these projects, and does not support them):

- lazyvim https://www.lazyvim.org/
- nvchad https://nvchad.com/
- kickstart https://github.com/nvim-lua/kickstart.nvim
  - Not recommended; use example-init instead.

However, we recommend (eventually) taking time to learn Nvim from its stock configuration, and incrementally setting options and adding plugins to your config as you discover a need.

Transitioning from Vim nvim-from-vim

1. To start the transition, create your init.vim (user config) file:

   ```
   :exe 'edit' stdpath('config') .. '/init.vim'
   :write ++p
   ```

2. Add these contents to the file:

   ```
   set runtimepath^=~/.vim runtimepath+=~/.vim/after
   let &packpath = &runtimepath
   source ~/.vimrc
   ```

3. Restart Nvim, your existing Vim config will be loaded.

   ```
   :restart
   ```

   See provider-python and provider-clipboard for additional software you might need to use some features.

Your Vim configuration might not be entirely Nvim-compatible (see vim-differences). For example the 'ttymouse' option was removed from Nvim, because mouse support is always enabled if possible. If you use the same vimrc for Vim and Nvim you could guard 'ttymouse' in your configuration like so:

```
if !has('nvim')
  set ttymouse=xterm2
endif
```

And for Nvim-specific configuration, you can do this:

```
if has('nvim')
  tnoremap <Esc> <C-\><C-n>
endif
```

For a more granular approach use exists():

```
if exists(':tnoremap')
  tnoremap <Esc> <C-\><C-n>
endif
```

Now you should be able to explore Nvim more comfortably. Check nvim-features for more information.

portable-config

Because Nvim follows the XDG base-directories standard, configuration on Windows is stored in ~/AppData instead of ~/.config. But you can still share the same Nvim configuration on all of your machines, by creating ~/AppData/Local/nvim/init.vim containing just this line:

```
source ~/.config/nvim/init.vim
```

Options

For an overview of options see quickref.txt option-list.

Vim has a number of internal variables and switches which can be set to
achieve special effects. These options come in three forms:

boolean	can only be on or off	boolean toggle
number	has a numeric value	
string	has a string value	

1. Setting options set-option E764

:se :set

:se[t][!] Show all options that differ from their default value.
When [!] is present every option is on a separate
line.

:se[t][!] all Show all options.
When [!] is present every option is on a separate
line.

E518 E519

:se[t] {option}? Show value of {option}.
NOTE: some legacy options were removed. nvim-removed

:se[t] {option} Toggle option: set, switch it on.
Number option: show value.
String option: show value.

:se[t] no{option} Toggle option: Reset, switch it off.

:set-! :set-inv

:se[t] {option}! or
:se[t] inv{option} Toggle option: Invert value.

:set-default :set-& :set-&vi :set-&vim

:se[t] {option}& Reset option to its default value.
:se[t] {option}&vi Reset option to its Vi default value.
:se[t] {option}&vim Reset option to its Vim default value.

:se[t] all& Set all options to their default value. The values of
these options are not changed:
'columns'
'lines'
Warning: This may have a lot of side effects.

:set-args :set= E487 E521

:se[t] {option}={value} or
:se[t] {option}:{value}
Set string or number option to {value}.
For numeric options the value can be given in decimal,
hex (preceded with 0x) or octal (preceded with '0' or
'0o').
The old value can be inserted by typing 'wildchar' (by
default this is a <Tab>). Many string options with
fixed syntax also support completing known values.
See cmdline-completion and complete-set-option.
White space between {option} and '=' is allowed and
will be ignored. White space between '=' and {value}
is not allowed.
See option-backslash for using white space and
backslashes in {value}.

:se[t] {option}+={value} :set+=

Add the {value} to a number option, or append the
{value} to a string option. When the option is a
comma-separated list, a comma is added, unless the
value was empty.
If the option is a list of flags, superfluous flags
are removed. When adding a flag that was already
present the option value doesn't change.
When the option supports "key:value" items and {value}
contains a "key:value" item or multiple
comma-separated items, each item is processed
individually:

- A "key:value" item where the key already exists with

a different value: the old item is removed and the
new item is appended to the end.

- A "key:value" item that is an exact duplicate is

left unchanged.

- Other items that already exist are left unchanged.

- New items are appended to the end.

Also see :set-args above.

:se[t] {option}^={value} :set^=

Multiply the {value} to a number option, or prepend

the {value} to a string option. When the option is a
comma-separated list, a comma is added, unless the
value was empty.
When the option supports "key:value" items and {value}
contains a "key:value" item or multiple
comma-separated items, each item is processed
individually. Works like :set+= but new items are
prepended to the beginning instead of appended.
Also see :set-args above.

:se[t] {option}-={value} :set-=

Subtract the {value} from a number option, or remove
the {value} from a string option, if it is there.
If the {value} is not found in a string option, there
is no error or warning. When the option is a comma-
separated list, a comma is deleted, unless the option
becomes empty.
When the option is a list of flags, {value} must be
exactly as they appear in the option. Remove flags
one by one to avoid problems.
When the option supports "key:value" items and {value}
contains a "key:value" item or multiple
comma-separated items, each item is processed
individually. A "key:value" item removes the existing
item with that key regardless of its value. A "key:"
item also removes by key match.
The individual values from a comma separated list or
list of flags can be inserted by typing 'wildchar'.
See complete-set-option.
Also see :set-args above.

The {option} arguments to ":set" may be repeated. For example:

```
:set ai nosi sw=3 ts=3
```

If you make an error in one of the arguments, an error message will be given
and the following arguments will be ignored.

:set-verbose

When 'verbose' is non-zero, displaying an option value will also tell where it
was last set. Example:

```
:verbose set shiftwidth cindent?
```

shiftwidth=4
Last set from modeline line 1
cindent
Last set from /usr/local/share/vim/vim60/ftplugin/c.vim line 30
This is only done when specific option values are requested, not for ":verbose
set all" or ":verbose set" without an argument.
When the option was set by hand there is no "Last set" message.
When the option was set while executing a function, user command or
autocommand, the script in which it was defined is reported.
A few special texts:
Last set from modeline line 1
		Option was set in a modeline.
Last set from --cmd argument
		Option was set with command line argument --cmd or +.
Last set from -c argument
		Option was set with command line argument -c, +, -S or
		-q.
Last set from environment variable
		Option was set from $VIMINIT.
Last set from error handler
		Option was cleared when evaluating it resulted in an error.

option-backslash

To include white space in a string option value it has to be preceded with a
backslash. To include a backslash you have to use two. Effectively this
means that the number of backslashes in an option value is halved (rounded
down).
In options 'path', 'cdpath', and 'tags', spaces have to be preceded with three
backslashes instead because they can be separated by either commas or spaces.
Comma-separated options like 'backupdir' and 'tags' will also require commas
to be escaped with two backslashes, whereas this is not needed for
non-comma-separated ones like 'makeprg'.
When setting options using :let and literal-string, you need to use one
fewer layer of backslash.
A few examples:

```
:set makeprg=make\ file     results in "make file"
:let &makeprg='make file'           (same as above)
:set makeprg=make\\\ file           results in "make\ file"
:set tags=tags\ /usr/tags           results in "tags" and "/usr/tags"
:set tags=tags\\\ file      results in "tags file"
:let &tags='tags\ file'     (same as above)

:set makeprg=make,file      results in "make,file"
:set makeprg=make\\,file            results in "make\,file"
:set tags=tags,file                 results in "tags" and "file"
:set tags=tags\\,file       results in "tags\,file"
:let &tags='tags\,file'     (same as above)
```

The "|" character separates a ":set" command from a following command. To include the "|" in the option value, use "\|" instead. This example sets the 'titlestring' option to "hi|there":

```
:set titlestring=hi\|there
```

This sets the 'titlestring' option to "hi" and 'iconstring' to "there":

```
:set titlestring=hi|set iconstring=there
```

Similarly, the double quote character starts a comment. To include the '"' in the option value, use '\"' instead. This example sets the 'titlestring' option to "hi "there"":

```
:set titlestring=hi\ \"there\"
```

For Win32 backslashes in file names are mostly not removed. More precise: For options that expect a file name (those where environment variables are expanded) a backslash before a normal file name character is not removed. But a backslash before a special character (space, backslash, comma, etc.) is used like explained above.
There is one special situation, when the value starts with "\\":

```
:set dir=\\machine\path     results in "\\machine\path"
:set dir=\\\\machine\\path          results in "\\machine\path"
:set dir=\\path\\file       results in "\\path\file" (wrong!)
```

For the first one the start is kept, but for the second one the backslashes are halved. This makes sure it works both when you expect backslashes to be halved and when you expect the backslashes to be kept. The third gives a result which is probably not what you want. Avoid it.

add-option-flags remove-option-flags

E539

Some options are a list of flags. When you want to add a flag to such an option, without changing the existing ones, you can do it like this:

```
:set guioptions+=a
```

Remove a flag from an option like this:

```
:set guioptions-=a
```

This removes the 'a' flag from 'guioptions'.
Note that you should add or remove one flag at a time. If 'guioptions' has the value "ab", using "set guioptions-=ba" won't work, because the string "ba" doesn't appear.

:set_env expand-env expand-environment-var

Environment variables in specific string options will be expanded. If the environment variable exists the '$' and the following environment variable name is replaced with its value. If it does not exist the '$' and the name are not modified. Any non-id character (not a letter, digit or '_') may follow the environment variable name. That character and what follows is appended to the value of the environment variable. Examples:

```
:set term=$TERM.new
:set path=/usr/$INCLUDE,$HOME/include,.
```

When adding or removing a string from an option with ":set opt-=val" or ":set opt+=val" the expansion is done before the adding or removing.

Handling of local options local-options

Note: The following also applies to global-local options.

Some of the options only apply to a window or buffer. Each window or buffer has its own copy of this option, thus each can have its own value. This allows you to set 'list' in one window but not in another. And set 'shiftwidth' to 3 in one buffer and 4 in another.

The following explains what happens to these local options in specific situations. You don't really need to know all of this, since Vim mostly uses the option values you would expect. Unfortunately, doing what the user expects is a bit complicated...

When splitting a window, the local options are copied to the new window. Thus right after the split the contents of the two windows look the same.

When editing a new buffer, its local option values must be initialized. Since the local options of the current buffer might be specifically for that buffer, these are not used. Instead, for each buffer-local option there also is a global value, which is used for new buffers. With ":set" both the local and global value is changed. With "setlocal" only the local value is changed, thus this value is not used when editing a new buffer.

When editing a buffer that has been edited before, the options from the window that was last closed are used again. If this buffer has been edited in this window, the values from back then are used. Otherwise the values from the last closed window where the buffer was edited last are used.

":setlocal" can be used to set a local window option specifically for a type of buffer. When you edit another buffer in the same window, you don't want to keep using these local window options. Meanwhile ":set" also sets a global value of a local window option, which is used when editing another buffer. Each window has its own copy of these global values, making them local to the window, but global to all buffers in the window. With this you can do:

```
:e one
:set list
:e two
```

Now the 'list' option will also be set in "two", since with the ":set list" command you have also set the global value.

```
:set nolist
:e one
:setlocal list
:e two
```

Now the 'list' option is not set, because ":set nolist" resets the global value, ":setlocal list" only changes the local value and ":e two" gets the global value. Note that if you do this next:

```
:e one
```

You will get back the 'list' value as it was the last time you edited "one". The options local to a window are remembered for each buffer. This also happens when the buffer is not loaded, but they are lost when the buffer is wiped out :bwipe.

Special local window options local-noglobal

The following local window options won't be copied over when new windows are created, thus they behave slightly differently:

Option	Reason
'previewwindow'	there can only be a single one
'scroll'	specific to existing window
'winfixbuf'	specific to existing window
'winfixheight'	specific to existing window
'winfixwidth'	specific to existing window
'winpinned'	specific to existing window

Special local buffer options

The following local buffer options won't be copied over when new buffers are created, thus they behave slightly differently:

Option	Reason
'filetype'	explicitly set by autocommands
'syntax'	explicitly set by autocommands
'bufhidden'	denote special-buffers
'buftype'	denote special-buffers
'readonly'	will be detected automatically
'modified'	will be detected automatically

:setl :setlocal

```
:setl[ocal][!] ...      Like ":set" but set only the value local to the
                        current buffer or window.  Not all options have a
                        local value.  If the option does not have a local
                        value the global value is set.
                        With the "all" argument: display local values for all
                        local options.
                        Without argument: Display local values for all local
                        options which are different from the default.
                        When displaying a specific local option, show the
```

local value. For a global/local boolean option, when
the global value is being used, "--" is displayed
before the option name.
For a global option the global value is
shown (but that might change in the future).

:se[t] {option}< Set the effective value of {option} to its global
value.
For global-local options, the local value is removed,
so that the global value will be used.
For all other options, the global value is copied to
the local value.

:setl[ocal] {option}< Set the effective value of {option} to its global
value by copying the global value to the local value.

Note that the behaviour for global-local options is slightly different
between string and number-based options.

:setg :setglobal

:setg[lobal][!] ... Like ":set" but set only the global value for a local
option without changing the local value.
When displaying an option, the global value is shown.
With the "all" argument: display global values for all
local options.
Without argument: display global values for all local
options which are different from the default.

For buffer-local and window-local options:

Command	global value	local value	condition
:set option=value	set	set	
:setlocal option=value	-	set	
:setglobal option=value	set	-	
:set option?	-	display	local value is set
:set option?	display	-	local value is not set
:setlocal option?	-	display	
:setglobal option?	display	-	

Global options with a local value global-local

Options are global when you mostly use one value for all buffers and windows.
For some global options it's useful to sometimes have a different local value.
You can set the local value with ":setlocal". That buffer or window will then
use the local value, while other buffers and windows continue using the global
value.

For example, you have two windows, both on C source code. They use the global
'makeprg' option. If you do this in one of the two windows:

```
:set makeprg=gmake
```

then the other window will switch to the same value. There is no need to set
the 'makeprg' option in the other C source window too.
However, if you start editing a Perl file in a new window, you want to use
another 'makeprg' for it, without changing the value used for the C source
files. You use this command:

```
:setlocal makeprg=perlmake
```

You can switch back to using the global value by making the local value empty:

```
:setlocal makeprg=
```

This only works for a string option. For a number or boolean option you need
to use the "<" flag, like this:

```
:setlocal autoread<
```

Note that for non-boolean and non-number options using "<" copies the global
value to the local value, it doesn't switch back to using the global value
(that matters when the global value changes later). You can also use:

```
:set path<
```

This will make the local value of 'path' empty, so that the global value is
used. Thus it does the same as:

```
:setlocal path=
```

Note: In the future more global options can be made global-local. Using
":setlocal" on a global option might work differently then.

option-value-function

Some options ('completefunc', 'findfunc', 'omnifunc', 'operatorfunc',
'quickfixtextfunc', 'tagfunc' and 'thesaurusfunc') can be set to a function
name, a Funcref, a lambda, or a Lua function.
Examples:

```
set opfunc=MyOpFunc
set opfunc=function('MyOpFunc')
set opfunc=funcref('MyOpFunc')
set opfunc={a\ ->\ MyOpFunc(a)}
```

Set to a script-local function:

```
set opfunc=s:MyLocalFunc
set opfunc=<SID>MyLocalFunc
```

Set using a funcref variable:

```
let Fn = function('MyTagFunc')
let &tagfunc = Fn
```

Set using a lambda expression:

```
let &tagfunc = {t -> MyTagFunc(t)}
```

Set using a variable with lambda expression:

```
let L = {a, b, c -> MyTagFunc(a, b , c)}
let &tagfunc = L
```

Set to a Lua function (from Lua):

```
vim.o.operatorfunc = function(motion) … end
```

The value read back from the option reflects how it was set:

- A Function name or Funcref reads back as the function name.
- A Vimscript lambda or partial reads back as an evaluatable string, e.g. function('<lambda>2') or function('MyFunc', [10]).
- A script-local ("s:") name is expanded to <SNR> form.
- A Lua function is returned as itself from Lua, or as a "<Lua …>" hint from Vimscript/RPC.
  - **Note:** Lua functions cannot be serialized, so it cannot be saved/restored by :mksession :mkview :mkvimrc.

Calling a function in an expr option expr-option-function

The value of an "expr" option ('charconvert', 'diffexpr', 'foldexpr', 'foldtext', 'formatexpr', 'includeexpr', 'indentexpr', 'patchexpr') is a Vimscript expression that is evaluated to get a value. Context is passed in v: variables, e.g. 'foldexpr' is evaluated for each line with v:lnum set.

The evaluation can have quite a bit of overhead. One way to minimize the overhead, and also to keep the option value very simple, is to define a function and set the option to call it without arguments. A v:lua-call can also be used. Example:

```
lua << EOF
  function _G.MyFoldFunc()
    -- ... compute fold level for line v:lnum
    return level
  end
EOF
set foldexpr=v:lua.MyFoldFunc()
```

From Lua the option can also be set directly to a function, which is called with no arguments (read the context from v: variables):

```
vim.wo.foldexpr = function() return vim.v.lnum == 1 and '>1' or '1' end
```

The value read back from the option follows the same rules as option-value-function: a string reads back as itself, and a Lua function reads back as the function (from Lua) or a "<Lua …>" hint (Vimscript/RPC).

Setting the filetype

:setf[iletype] [FALLBACK] {filetype} :setf :setfiletype

Set the 'filetype' option to {filetype}, unless it was already set (non-empty) in a sequence of (nested) autocommands.
This is short for:

```
:if !did_filetype()
:  setlocal filetype={filetype}
:endif
```

Used in a filetype.vim file to avoid setting the 'filetype' option twice, causing different settings and syntax files to be loaded.

When the optional FALLBACK argument is present, a later :setfiletype command will override the 'filetype'. This is to be used for filetype detections that are just a guess. did_filetype() will return false after this command.

option-window optwin
:bro[wse] se[t] :set-browse :browse-set :opt :options
:opt[ions] Open a window for viewing and setting all options.
Options are grouped by function.
Offers short help for each option. Hit <CR> on the short help to open a help window with more help for the option.
Modify the value of the option and hit <CR> on the "set" line to set the new value. For window and buffer specific options, the last accessed window is used to set the option value in, unless this is a help window, in which case the window below help window is used (skipping the option-window).

$HOME

Using "~" is like using "$HOME", but it is only recognized at the start of an option and after a space or comma.

On Unix systems "~user" can be used too. It is replaced by the home directory of user "user". Example:

```
:set path=~mool/include,/usr/include,.
```

On Unix systems the form "${HOME}" can be used too. The name between {} can contain non-id characters then. Note that if you want to use this for the "gf" command, you need to add the '{' and '}' characters to 'isfname'.

NOTE: expanding environment variables and "~/" is only done with the ":set" command, not when assigning a value to an option with ":let".

$HOME-windows

On MS-Windows, if $HOME is not defined as an environment variable, then at runtime Vim will set it to the expansion of $HOMEDRIVE$HOMEPATH. If $HOMEDRIVE is not set then $USERPROFILE is used.

This expanded value is not exported to the environment, this matters when running an external command:

```
:echo system('set | findstr ^HOME=')
```

and

```
:echo luaeval('os.getenv("HOME")')
```

should echo nothing (an empty string) despite exists('$HOME') being true. When setting $HOME to a non-empty string it will be exported to the subprocesses.

Note the maximum length of an expanded option is limited. How much depends on the system, mostly it is something like 256 or 1024 characters.

2. Automatically setting options auto-setting

Besides changing options with the ":set" command, you can set options automatically in various ways:

1. With a config file or a startup argument. You can create an initialization file with :mkvimrc, :mkview and :mksession.
2. autocommands executed when you edit a file.
3. ".nvim.lua" files in the current directory, if 'exrc' is enabled.
4. editorconfig in the current buffer's directory or ancestors.
5. 'modeline' settings found at the beginning or end of the file. See below.

modeline vim: vi: ex: E520
There are two forms of modelines. The first form:
[text{white}]{vi:|vim:|ex:}[white]{options}

```
[text{white}]           empty or any text followed by at least one blank
                        character (<Space> or <Tab>); "ex:" always requires at
                        least one blank character
{vi:|vim:|ex:}          the string "vi:", "vim:" or "ex:"
[white]                 optional white space
{options}               a list of option settings, separated with white space
                        or ':', where each part between ':' is the argument
                        for a ":set" command (can be empty)
```

Examples:
vi:noai:sw=3 ts=6
vim: tw=77

The second form (this is compatible with some versions of Vi):

```
        [text{white}]{vi:|vim:|Vim:|ex:}[white]se[t] {options}:[text]
```

```
[text{white}]           empty or any text followed by at least one blank
                        character (<Space> or <Tab>); "ex:" always requires at
                        least one blank character
{vi:|vim:|Vim:|ex:}     the string "vi:", "vim:", "Vim:" or "ex:"
[white]                 optional white space
se[t]                   the string "set " or "se " (note the space); When
                        "Vim" is used it must be "set".
{options}               a list of options, separated with white space, which
                        is the argument for a ":set" command
:                       a colon
[text]                  any text or empty
```

Examples:

```
/* vim: set ai tw=75: */
/* Vim: set ai tw=75: */
```

The white space before {vi:|vim:|Vim:|ex:} is required. This minimizes the chance that a normal word like "lex:" is caught. There is one exception: "vi:" and "vim:" can also be at the start of the line (for compatibility with version 3.0). Using "ex:" at the start of the line will be ignored (this could be short for "example:").

If the modeline is disabled within a modeline, subsequent modelines will be ignored. This is to allow turning off modeline on a per-file basis. This is useful when a line looks like a modeline but isn't. For example, it would be good to start a YAML file containing strings like "vim:" with
vim: nomodeline
so as to avoid modeline misdetection. Following options on the same line after modeline deactivation, if any, are still evaluated (but you would normally not have any).

modeline-local

The options are set like with ":setlocal": The new value only applies to the buffer and window that contain the file. Although it's possible to set global options from a modeline, this is unusual. If you have two windows open and the files in it set the same global option to a different value, the result depends on which one was opened last.

When editing a file that was already loaded, only the window-local options from the modeline are used. Thus if you manually changed a buffer-local option after opening the file, it won't be changed if you edit the same buffer in another window. But window-local options will be set.

modeline-version

If the modeline is only to be used for some versions of Vim, the version number can be specified where "vim:" or "Vim:" is used:

```
        vim{vers}:      version {vers} or later
        vim<{vers}:     version before {vers}
        vim={vers}:     version {vers}
        vim>{vers}:     version after {vers}
```

{vers} is 700 for Vim 7.0 (hundred times the major version plus minor).
For example, to use a modeline only for Vim 7.0:

```
/* vim700: set foldmethod=marker */
```

To use a modeline for Vim after version 7.2:

```
/* vim>702: set cole=2: */
```

There can be no blanks between "vim" and the ":".
The modeline is ignored if {vers} does not fit in an integer.

The number of lines that are checked can be set with the 'modelines' option.
If 'modeline' is off or 'modelines' is 0 no lines are checked.

Note that for the first form all of the rest of the line is used, thus a line like:

```
/* vi:ts=4: */
```

will give an error message for the trailing "*/". This line is OK:

```
/* vi:set ts=4: */
```

If an error is detected the rest of the line is skipped.

If you want to include a ':' in a set command precede it with a '\'. The backslash in front of the ':' will be removed. Example:

```
/* vi:set fillchars=stl\:^,vert\:\|: */
```

This sets the 'fillchars' option to "stl:^,vert:\|". Only a single backslash before the ':' is removed. Thus to include "\:" you have to specify "\\:".

E992 no-modeline-option

No other commands than "set" are supported, for security reasons (somebody might create a Trojan horse text file with modelines). And not all options can be set. For some options a flag is set, so that when the value is used the sandbox is effective. Some options can only be set from the modeline when 'modelineexpr' is set (the default is off).

Still, there is always a small risk that a modeline causes trouble. E.g., when some joker sets 'textwidth' to 5 all your lines are wrapped unexpectedly. So disable modelines before editing untrusted text. The mail ftplugin does this, for example.

Hint: If you would like to do something else than setting an option, you could define an autocommand that checks the file for a specific string. For example:

```
au BufReadPost * if getline(1) =~ "VAR" | call SetVar() | endif
```

And define a function SetVar() that does something with the line containing "VAR".

3. Options summary option-summary

In the list below all the options are mentioned with their full name and with an abbreviation if there is one. Both forms may be used.

In this document when a boolean option is "set" that means that ":set option" is entered. When an option is "reset", ":set nooption" is used.

Most options are the same in all windows and buffers. There are a few that are specific to how the text is presented in a window. These can be set to a different value in each window. For example the 'list' option can be set in one window and reset in another for the same text, giving both types of view at the same time. There are a few options that are specific to a certain file. These can have a different value for each file or buffer. For example the 'textwidth' option can be 78 for a normal text file and 0 for a C program.

global	one option for all buffers and windows
local to window	each window has its own copy of this option
local to buffer	each buffer has its own copy of this option

When creating a new window the option values from the currently active window are used as a default value for the window-specific options. For the buffer-specific options this depends on the 's' and 'S' flags in the 'cpoptions' option. If 's' is included (which is the default) the values for buffer options are copied from the currently active buffer when a buffer is first entered. If 'S' is present the options are copied each time the buffer is entered, this is almost like having global options. If 's' and 'S' are not present, the options are copied from the currently active buffer when the buffer is created.

Hidden options hidden-options

Not all options are supported in all versions. This depends on the supported features and sometimes on the system. A remark about this is in curly braces below. When an option is not supported, it is called a hidden option. Trying to get the value of a hidden option will not give an error, it will return the default value for that option instead. You can't change the value of a hidden option.

To test if "foo" is a valid option name, use something like this:

```
if exists('&foo')
```

This also returns true for a hidden option. To test if option "foo" is really supported use something like this:

```
if exists('+foo')
```

E355

A jump table for the options with a short description can be found at Q_op.

'allowrevins' 'ari' 'noallowrevins' 'noari'
'allowrevins' 'ari' boolean (default off)
global
Allow CTRL-_ in Insert mode. This is default off, to avoid that users that accidentally type CTRL-_ instead of SHIFT-_ get into reverse Insert mode, and don't know how to get out. See 'revins'.

'ambiwidth' 'ambw'

'ambiwidth' 'ambw' string (default "single")
global

Tells Vim what to do with characters with East Asian Width Class Ambiguous (such as Euro, Registered Sign, Copyright Sign, Greek letters, Cyrillic letters).

There are currently two possible values:

"single": Use the same width as characters in US-ASCII. This is expected by most users.

"double": Use twice the width of ASCII characters.

E834 E835

The value "double" cannot be used if 'listchars' or 'fillchars' contains a character that would be double width. These errors may also be given when calling setcellwidths().

The values are overruled for characters specified with setcellwidths().

There are a number of CJK fonts for which the width of glyphs for those characters are solely based on how many octets they take in legacy/traditional CJK encodings. In those encodings, Euro, Registered sign, Greek/Cyrillic letters are represented by two octets, therefore those fonts have "wide" glyphs for them. This is also true of some line drawing characters used to make tables in text file. Therefore, when a CJK font is used for GUI Vim or Vim is running inside a terminal (emulators) that uses a CJK font (or Vim is run inside an xterm invoked with "-cjkwidth" option.), this option should be set to "double" to match the width perceived by Vim with the width of glyphs in the font. Perhaps it also has to be set to "double" under CJK MS-Windows when the system locale is set to one of CJK locales. See Unicode Standard Annex #11 (https://www.unicode.org/reports/tr11).

'arabic' 'arab' 'noarabic' 'noarab'

'arabic' 'arab' boolean (default off)
local to window

This option can be set to start editing Arabic text.
Setting this option will:

- Set the 'rightleft' option, unless 'termbidi' is set.
- Set the 'arabicshape' option, unless 'termbidi' is set.
- Set the 'keymap' option to "arabic"; in Insert mode CTRL-^ toggles between typing English and Arabic key mapping.
- Set the 'delcombine' option

Resetting this option will:

- Reset the 'rightleft' option.
- Disable the use of 'keymap' (without changing its value).

Note that 'arabicshape' and 'delcombine' are not reset (it is a global option).
Also see l10n-arabic.txt.

'arabicshape' 'arshape' 'noarabicshape' 'noarshape'

'arabicshape' 'arshape' boolean (default on)
global

When on and 'termbidi' is off, the required visual character corrections that need to take place for displaying the Arabic language take effect. Shaping, in essence, gets enabled; the term is a broad one which encompasses:

a) the changing/morphing of characters based on their location within a word (initial, medial, final and stand-alone).
b) the enabling of the ability to compose characters
c) the enabling of the required combining of some characters

When disabled the display shows each character's true stand-alone form.
Arabic is a complex language which requires other settings, for further details see l10n-arabic.txt.

'autochdir' 'acd' 'noautochdir' 'noacd'

'autochdir' 'acd' boolean (default off)
global

When on, Nvim will change its global current-directory to the parent of the current file, whenever you open a file, switch buffers, delete a buffer or open/close a window.

When a buffer has no name it also has no directory, thus the current directory won't change when navigating to it.

Note: When this option is on some plugins may not work.

Alternatively, consider using :bcd, :lcd, or :tcd in an autocmd, to selectively set a local (not global) directory. See project-dir.

'autocomplete' 'ac' 'noautocomplete' 'noac'
'autocomplete' 'ac'	boolean (default off)
global or local to buffer global-local
When on, Vim shows a completion menu as you type, similar to using i_CTRL-N, but triggered automatically. See ins-autocompletion.

'autocompletedelay' 'acl'
'autocompletedelay' 'acl'	number (default 0)
global
Delay in milliseconds before the autocomplete menu appears after typing. If you prefer it not to open too quickly, set this value slightly above your typing speed. See ins-autocompletion.

'autocompletetimeout' 'act'
'autocompletetimeout' 'act'	number (default 80)
global
Initial timeout (in milliseconds) for the decaying time-sliced completion algorithm. Starts at this value, halves for each slower source until a minimum is reached. All sources run, but slower ones are quickly de-prioritized. The default is tuned so the popup menu opens within ~200ms even with multiple slow sources on a slow system. Changing this value is rarely needed. Only 80 or higher is valid. Special case: when 'complete' contains "F" or "o" (function sources), a longer timeout is used, allowing up to ~1s for sources such as LSP servers that may sometimes take longer (e.g., while loading modules). See ins-autocompletion.

'autoindent' 'ai' 'noautoindent' 'noai'
'autoindent' 'ai'	boolean (default on)
local to buffer
Copy indent from current line when starting a new line (typing <CR> in Insert mode or when using the "o" or "O" command). If you do not type anything on the new line except <BS> or CTRL-D and then type <Esc>, CTRL-O or <CR>, the indent is deleted again. Moving the cursor to another line has the same effect, unless the 'I' flag is included in 'cpoptions'.
When autoindent is on, formatting (with the "gq" command or when you reach 'textwidth' in Insert mode) uses the indentation of the first line.
When 'smartindent' or 'cindent' is on the indent is changed in a different way.

'autoread' 'ar' 'noautoread' 'noar'
'autoread' 'ar'	boolean (default on)
global or local to buffer global-local
When a file was changed outside of Nvim, automatically read it again. Skipped if the file was deleted (so you still have the last-available text). If the file appears again, then it is read; you can undo to see the previous contents. timestamp

This is driven (partially) by OS filewatcher events uv_fs_event_t, so buffers are updated immediately (instead of only on focus-change or shell-commands).

If this option has a local value, use this command to switch back to using the global value:

```
set autoread<
```

'autowrite' 'aw' 'noautowrite' 'noaw'
'autowrite' 'aw'	boolean (default off)
global
Write the contents of the file, if it has been modified, on each :next, :rewind, :last, :first, :previous, :tag, :stop, :suspend, :!, :make, :terminal, CTRL-] or CTRL-^ command; and when a :buffer, CTRL-O, CTRL-I, '{A-Z0-9}, or `{A-Z0-9} command switches to another file.
A buffer is not written if it becomes hidden, e.g. when 'bufhidden' is set to "hide" and :next is used.
Note that for some commands the 'autowrite' option is not used, see 'autowriteall' for that.
Some buffers will not be written, specifically when 'buftype' is "nowrite", "nofile", "terminal" or "prompt".
USE WITH CARE: If you make temporary changes to a buffer that you don't want to be saved this option may cause it to be saved anyway. Renaming the buffer with ":file {name}" may help avoid this.

'autowriteall' 'awa' 'noautowriteall' 'noawa'
'autowriteall' 'awa'	boolean (default off)
global
Like 'autowrite', but also used for commands :edit, :enew, :quit, :qall, :exit, :xit, :recover and closing the Vim window.
Setting this option also implies that Vim behaves like 'autowrite' has been set.

'background' 'bg'
'background' 'bg'	string (default "dark")
global
When set to "dark" or "light", adjusts the default color groups for that background type. The TUI or other UI sets this on startup if it can detect the background color, and re-detects it whenever a UI attaches later, unless 'background' was set explicitly. When multiple UIs are attached they share one value, decided by "last wins" (may

not be the most recently-attached UI, since it depends on response speed).

This option does NOT change the background color, it tells Nvim what the "inherited" (terminal/GUI) background looks like. See :hi-normal to set the background color explicitly.

g:colors_name

When a color scheme is loaded (the "g:colors_name" variable is set) changing 'background' will cause the color scheme to be reloaded. If the color scheme adjusts to the value of 'background' this will work. However, if the color scheme sets 'background' itself the effect may be undone. First delete the "g:colors_name" variable when needed.

Historically, this option was set in the vimrc file. Example:

```
if $TERM ==# "xterm"
  set background=dark
endif
```

When this option is changed, the defaults for highlight groups will change. To override those defaults, place ":highlight" commands AFTER setting the 'background' option.

'backspace' 'bs'

'backspace' 'bs' string (default "indent,eol,start")
global

Influences the working of <BS>, <Del>, CTRL-W and CTRL-U in Insert mode. This is a list of items, separated by commas. Each item allows a way to backspace over something:

value	effect
indent	allow backspacing over autoindent
eol	allow backspacing over line breaks (join lines)
start	allow backspacing over the start of insert; CTRL-W and CTRL-U stop once at the start of insert.
nostop	like start, except CTRL-W and CTRL-U do not stop at the start of insert.

When the value is empty, Vi compatible backspacing is used, none of the ways mentioned for the items above are possible.

'backup' 'bk' 'nobackup' 'nobk'

'backup' 'bk' boolean (default off)
global

Make a backup before overwriting a file. Leave it around after the file has been successfully written. If you do not want to keep the backup file, but you do want a backup while the file is being written, reset this option and set the 'writebackup' option (this is the default). If you do not want a backup file at all reset both options (use this if your file system is almost full). See the backup-table for more explanations.
When the 'backupskip' pattern matches, a backup is not made anyway.
When 'patchmode' is set, the backup may be renamed to become the oldest version of a file.

'backupcopy' 'bkc'

'backupcopy' 'bkc' string (default "auto")
global or local to buffer global-local

When writing a file and a backup is made, this option tells how it's done. This is a comma-separated list of words.

The main values are:
"yes" make a copy of the file and overwrite the original one
"no" rename the file and write a new one
"auto" one of the previous, what works best

Extra values that can be combined with the ones above are:
"breaksymlink" always break symlinks when writing
"breakhardlink" always break hardlinks when writing

Making a copy and overwriting the original file:
- Takes extra time to copy the file.

  + When the file has special attributes, is a (hard/symbolic) link or has a resource fork, all this is preserved.
- When the file is a link the backup will have the name of the link,

  not of the real file.

Renaming the file and writing a new one:
+ It's fast.
- Sometimes not all attributes of the file can be copied to the new

  file.
- When the file is a link the new file will not be a link.

The "auto" value is the middle way: When Vim sees that renaming the file is possible without side effects (the attributes can be passed on and the file is not a link) that is used. When problems are expected, a copy will be made.

The "breaksymlink" and "breakhardlink" values can be used in combination with any of "yes", "no" and "auto". When included, they force Vim to always break either symbolic or hard links by doing exactly what the "no" option does, renaming the original file to become the backup and writing a new file in its place. This can be useful for example in source trees where all the files are symbolic or hard links and any changes should stay in the local source tree, not be propagated back to the original source.

crontab

One situation where "no" and "auto" will cause problems: A program that opens a file, invokes Vim to edit that file, and then tests if the open file was changed (through the file descriptor) will check the backup file instead of the newly created file. "crontab -e" is an example, as are several file-watcher daemons like inotify. In that case you probably want to switch this option.

When a copy is made, the original file is truncated and then filled with the new text. This means that protection bits, owner and symbolic links of the original file are unmodified. The backup file, however, is a new file, owned by the user who edited the file. The group of the backup is set to the group of the original file. If this fails, the protection bits for the group are made the same as for others.

When the file is renamed, this is the other way around: The backup has the same attributes of the original file, and the newly written file is owned by the current user. When the file was a (hard/symbolic) link, the new file will not! That's why the "auto" value doesn't rename when the file is a link. The owner and group of the newly written file will be set to the same ones as the original file, but the system may refuse to do this. In that case the "auto" value will again not rename the file.

'backupdir' 'bdir'

'backupdir' 'bdir' string (default ".,$XDG_STATE_HOME/nvim/backup//")
global
Disallowed in modeline. no-modeline-option

List of directories for the backup file, separated with commas.

- The backup file will be created in the first directory in the list where this is possible. If none of the directories exist Nvim will attempt to create the last directory in the list.
- Empty means that no backup file will be created ('patchmode' is impossible!). Writing may fail because of this.
- A directory "." means to put the backup file in the same directory as the edited file.
- A directory starting with "./" (or ".\" for MS-Windows) means to put the backup file relative to where the edited file is. The leading "." is replaced with the path name of the edited file. ("." inside a directory name has no special meaning).
- Spaces after the comma are ignored, other spaces are considered part of the directory name. To have a space at the start of a directory name, precede it with a backslash.
- To include a comma in a directory name precede it with a backslash.
- A directory name may end in an '/'.
- For Unix and Win32, if a directory ends in two path separators "//", the swap file name will be built from the complete path to the file with all path separators changed to percent '%' signs. This will ensure file name uniqueness in the backup directory. On Win32, it is also possible to end with "\\". However, When a separating comma is following, you must use "//", since "\\" will include the comma in the file name. Therefore it is recommended to use '//', instead of '\\'.
- Environment variables are expanded :set_env.
- Careful with '\' characters, type one before a space, type two to get one in the option (see option-backslash), for example:

```
set bdir=c:\\tmp,\ dir\\,with\\,commas,\\\ dir\ with\ spaces
```

See also 'backup' and 'writebackup' options.
If you want to hide your backup files on Unix, consider this value:

```
set backupdir=./.backup,~/.backup,.,/tmp
```

You must create a ".backup" directory in each directory and in your
home directory for this to work properly.
The use of :set+= and :set-= is preferred when adding or removing
directories from the list. This avoids problems when a future version
uses another default.

'backupext' 'bex' E589
'backupext' 'bex'	string (default "~")
global
String which is appended to a file name to make the name of the
backup file. The default is quite unusual, because this avoids
accidentally overwriting existing files with a backup file. You might
prefer using ".bak", but make sure that you don't have files with
".bak" that you want to keep.
Only normal file name characters can be used; /*?[|<> are illegal.

If you like to keep a lot of backups, you could use a BufWritePre
autocommand to change 'backupext' just before writing the file to
include a timestamp.

```
au BufWritePre * let &bex = '-' .. strftime("%Y%b%d%X") .. '~'
```

Use 'backupdir' to put the backup in a different directory.

'backupskip' 'bsk'
'backupskip' 'bsk'	string (default "$TMPDIR/*,$TMP/*,$TEMP/*"
Unix: "/tmp/*,$TMPDIR/*,$TMP/*,$TEMP/*"
Mac: "/private/tmp/*,$TMPDIR/*,$TMP/*,$TEMP/*")
global
A list of file patterns. When one of the patterns matches with the
name of the file which is written, no backup file is created. Both
the specified file name and the full path name of the file are used.
The pattern is used like with :autocmd, see autocmd-pattern.
Watch out for special characters, see option-backslash.
When $TMPDIR, $TMP or $TEMP is not defined, it is not used for the
default value. "/tmp/*" is only used for Unix.

WARNING: Not having a backup file means that when Vim fails to write
your buffer correctly and then, for whatever reason, Vim exits, you
lose both the original file and what you were writing. Only disable
backups if you don't care about losing the file.

Note that environment variables are not expanded. If you want to use
$HOME you must expand it explicitly, e.g.:

```
let &backupskip = escape(expand('$HOME'), '\') .. '/tmp/*'
```

Note that the default also makes sure that "crontab -e" works (when a
backup would be made by renaming the original file crontab won't see
the newly created file). Also see 'backupcopy' and crontab.

'belloff' 'bo'
'belloff' 'bo'	string (default "all")
global
Specifies for which events the bell will not be rung. It is a comma-
separated list of items. For each item that is present, the bell will
be silenced. This is most useful to specify specific events in insert
mode to be silenced.
You can also make it flash by using 'visualbell'.

item	meaning when present
all	All events. backspace When hitting <BS> or <Del> and deleting results in an error.
cursor	Fail to move around using the cursor keys or <PageUp>/<PageDown> in Insert-mode. complete Error occurred when using i_CTRL-X_CTRL-K or i_CTRL-X_CTRL-T.
copy	Cannot copy char from insert mode using i_CTRL-Y or i_CTRL-E.
ctrlg	Unknown Char after <C-G> in Insert mode.
error	Other Error occurred (e.g. try to join last line) (mostly used in Normal-mode or Cmdline-mode).
esc	hitting <Esc> in Normal-mode.
hangul	Ignored.
lang	Calling the beep module for Lua/Mzscheme/TCL.
mess	No output available for g<. showmatch Error occurred for 'showmatch' function. operator Empty region error cpo-E. register Unknown register after <C-R> in Insert-mode.
shell	Bell from shell output :!.
spell	Error happened on spell suggest.
term	Bell from :terminal output. wildmode More matches in cmdline-completion available (depends on the 'wildmode' setting).

This is most useful to fine tune when in Insert mode the bell should
be rung. For Normal mode and Ex commands, the bell is often rung to
indicate that an error occurred. It can be silenced by adding the
"error" keyword.

'binary' 'bin' 'nobinary' 'nobin'
'binary' 'bin'	boolean (default off)

local to buffer
This option should be set before editing a binary file. You can also use the -b Vim argument. When this option is switched on a few options will be changed (also when it already was on):
'textwidth' will be set to 0
'wrapmargin' will be set to 0
'modeline' will be off
'expandtab' will be off
Also, 'fileformat' and 'fileformats' options will not be used, the file is read and written like 'fileformat' was "unix" (a single <NL> separates lines).
The 'fileencoding' and 'fileencodings' options will not be used, the file is read without conversion.
NOTE: When you start editing a(nother) file while the 'bin' option is on, settings from autocommands may change the settings again (e.g., 'textwidth'), causing trouble when editing. You might want to set 'bin' again when the file has been loaded.
The previous values of these options are remembered and restored when 'bin' is switched from on to off. Each buffer has its own set of saved option values.
To edit a file with 'binary' set you can use the ++bin argument. This avoids you have to do ":set bin", which would have effect for all files you edit.
When writing a file the <EOL> for the last line is only written if there was one in the original file (normally Vim appends an <EOL> to the last line if there is none; this would make the file longer). See the 'endofline' option.

'bomb' 'nobomb'
'bomb' boolean (default off)
local to buffer
When writing a file and the following conditions are met, a BOM (Byte Order Mark) is prepended to the file:

- this option is on
- the 'binary' option is off
- 'fileencoding' is "utf-8", "ucs-2", "ucs-4" or one of the little/big endian variants.

Some applications use the BOM to recognize the encoding of the file. Often used for UCS-2 files on MS-Windows. For other applications it causes trouble, for example: "cat file1 file2" makes the BOM of file2 appear halfway through the resulting file. Gcc doesn't accept a BOM.
When Vim reads a file and 'fileencodings' starts with "ucs-bom", a check for the presence of the BOM is done and 'bomb' set accordingly. Unless 'binary' is set, it is removed from the first line, so that you don't see it when editing. When you don't change the options, the BOM will be restored when writing the file.

'breakat' 'brk'
'breakat' 'brk' string (default " ^I!@*-+;:,./?")
global
This option lets you choose which characters might cause a line break if 'linebreak' is on. Only works for ASCII characters.

'breakindent' 'bri' 'nobreakindent' 'nobri'
'breakindent' 'bri' boolean (default off)
local to window
Every wrapped line will continue visually indented (same amount of space as the beginning of that line), thus preserving horizontal blocks of text.

'breakindentopt' 'briopt'
'breakindentopt' 'briopt' string (default "")
local to window
Settings for 'breakindent'. It can consist of the following optional items and must be separated by a comma:

min:{n}	Minimum text width that will be kept after applying 'breakindent', even if the resulting text should normally be narrower. This prevents text indented almost to the right window border occupying lots of vertical space when broken. (default: 20)
shift:{n}	After applying 'breakindent', the wrapped line's beginning will be shifted by the given number of characters. It permits dynamic French paragraph indentation (negative) or emphasizing the line continuation (positive). (default: 0)
sbr	Display the 'showbreak' value before applying the additional indent. (default: off)
list:{n}	Adds an additional indent for lines that match a numbered or bulleted list (using the 'formatlistpat' setting). (default: 0)
list:-1	Uses the width of a match with 'formatlistpat' for indentation.

column:{n} Indent at column {n}. Will overrule the other
sub-options. **Note:** an additional indent may be
added for the 'showbreak' setting.
(default: off)

'bufhidden' 'bh'

'bufhidden' 'bh' string (default "")
local to buffer local-noglobal

This option specifies what happens when a buffer is no longer
displayed in a window:

<empty>	follow the global 'hidden' option
hide	hide the buffer (don't unload it), even if 'hidden' is not set
unload	unload the buffer, even if 'hidden' is set; the :hide command will also unload the buffer
delete	delete the buffer from the buffer list, even if 'hidden' is set; the :hide command will also delete the buffer, making it behave like :bdelete
wipe	wipe the buffer from the buffer list, even if 'hidden' is set; the :hide command will also wipe out the buffer, making it behave like :bwipeout

CAREFUL: when "unload", "delete" or "wipe" is used changes in a buffer
are lost without a warning. Also, these values may break autocommands
that switch between buffers temporarily.
This option is used together with 'buftype' and 'swapfile' to specify
special kinds of buffers. See special-buffers.

'buflisted' 'bl' 'nobuflisted' 'nobl' E85

'buflisted' 'bl' boolean (default on)
local to buffer

When this option is set, the buffer shows up in the buffer list. If
it is reset it is not used for ":bnext", "ls", the Buffers menu, etc.
This option is reset by Vim for buffers that are only used to remember
a file name or marks. Vim sets it when starting to edit a buffer.
But not when moving to a buffer with ":buffer".

'buftype' 'bt' E382

'buftype' 'bt' string (default "")
local to buffer local-noglobal

The value of this option specifies the type of a buffer:

(empty)	Normal buffer.
acwrite	Buffer will always be written with BufWriteCmd.
help	Help buffer (do not set this manually).
nofile	Buffer is not a file, will not be written.
nowrite	Buffer represents a filepath (such as a directory), but will not be written.
prompt	Buffer where only the last section can be edited, for use by plugins. prompt-buffer
quickfix	List of errors :cwindow or locations :lwindow
terminal	terminal-emulator buffer

This option is used together with 'bufhidden' and 'swapfile' to
specify special kinds of buffers. See special-buffers.
Also see win_gettype(), which returns the type of the window.

Be careful with changing this option, it can have many side effects!
One such effect is that Vim will not check the timestamp of the file,
if the file is changed by another program this will not be noticed.

A "quickfix" buffer is only used for the error list and the location
list. This value is set by the :cwindow and :lwindow commands and
you are not supposed to change it.

"nofile" and "nowrite" buffers are similar:

both:	The buffer is not to be written to disk, ":w" doesn't work (":w filename" does work though).
both:	The buffer is never considered to be 'modified'. There is no warning when the changes will be lost, for example when you quit Vim.
both:	A swap file is only created when using too much memory (when 'swapfile' has been reset there is never a swap file).
nofile only:	The buffer name is fixed, it is not handled like a file name. It is not modified in response to a :cd command.
both:	When using ":e bufname" and already editing "bufname" the buffer is made empty and autocommands are triggered as usual for :edit.

E676

"acwrite" implies that the buffer name is not related to a file, like
"nofile", but it will be written. Thus, in contrast to "nofile" and
"nowrite", ":w" does work and a modified buffer can't be abandoned
without saving. For writing there must be matching BufWriteCmd,
FileWriteCmd or FileAppendCmd autocommands.

'busy'

'busy' number (default 0)
local to buffer

Sets a buffer "busy" status. Indicated in the default statusline.
When busy status is larger then 0 busy flag is shown in statusline.
The semantics of "busy" are arbitrary, typically decided by the plugin that owns the buffer.

'casemap' 'cmp'

'casemap' 'cmp'		string (default "internal,keepascii")
			global
	Specifies details about changing the case of letters. It may contain
	these words, separated by a comma:
	internal	Use internal case mapping functions, the current
			locale does not change the case mapping. When
			"internal" is omitted, the towupper() and towlower()
			system library functions are used when available.
	keepascii	For the ASCII characters (0x00 to 0x7f) use the US
			case mapping, the current locale is not effective.
			This probably only matters for Turkish.

'cdhome' 'cdh' 'nocdhome' 'nocdh'

'cdhome' 'cdh'		boolean (default on on Unix, off on Windows)
			global
			Disallowed in modeline. no-modeline-option
	When on, :cd, :tcd, :lcd and :bcd without an argument changes the
	current working directory to the $HOME directory like in Unix.
	When off, those commands just print the current directory name.

'cdpath' 'cd' E344 E346

'cdpath' 'cd'		string (default equivalent to $CDPATH or ",,")
			global
			Disallowed in modeline. no-modeline-option
	This is a list of directories which will be searched when using the
	:cd, :tcd, :lcd and :bcd commands, provided that the directory being
	searched for has a relative path, not an absolute part starting with
	"/", "./" or "../", the 'cdpath' option is not used then.
	The 'cdpath' option's value has the same form and semantics as
	'path'. Also see file-searching.
	The default value is taken from $CDPATH, with a "," prepended to look
	in the current directory first.
	If the default value taken from $CDPATH is not what you want, include
	a modified version of the following command in your vimrc file to
	override it:

```
let &cdpath = ',' .. substitute(substitute($CDPATH, '[, ]', '\\\0', 'g'), ':', ',', 'g')
```

	Environment variables are expanded :set_env.
	(parts of 'cdpath' can be passed to the shell to expand file names).

'cedit'

'cedit'			string (default CTRL-F)
			global
	The key used in Command-line Mode to open the command-line window.
	Only non-printable keys are allowed.
	The key can be specified as a single character, but it is difficult to
	type. The preferred way is to use key-notation (e.g. <Up>, <C-F>) or
	a letter preceded with a caret (e.g. ^F is CTRL-F). Examples:

```
set cedit=^Y
set cedit=<Esc>
```

	Nvi also has this option, but it only uses the first character.
	See cmdwin.

'channel'

'channel'		number (default 0)
			local to buffer
	channel connected to the buffer, or 0 if no channel is connected.
	In a :terminal buffer this is the terminal channel.
	Read-only.

'charconvert' 'ccv' E202 E214 E513

'charconvert' 'ccv'	string (default "")
			global
			Disallowed in modeline. no-modeline-option
	An expression that is used for character encoding conversion. It is
	evaluated when a file that is to be read or has been written has a
	different encoding from what is desired.
	'charconvert' is not used when the internal iconv() function is
	supported and is able to do the conversion. Using iconv() is
	preferred, because it is much faster.
	'charconvert' is not used when reading stdin --, because there is no
	file to convert from. You will have to save the text in a file first.
	The expression must return zero, false or an empty string for success,
	non-zero or true for failure.
	See encoding-names for possible encoding names.
	Additionally, names given in 'fileencodings' and 'fileencoding' are
	used.
	Conversion between "latin1", "unicode", "ucs-2", "ucs-4" and "utf-8"
	is done internally by Vim, 'charconvert' is not used for this.
	Also used for Unicode conversion.
	Example:

```
vim.o.charconvert = function()
  vim.fn.system(('recode %s..%s <%s >%s'):format(
    vim.v.charconvert_from, vim.v.charconvert_to,
    vim.v.fname_in, vim.v.fname_out))
  return vim.v.shell_error
end
```

The related Vim variables are:
```
        v:charconvert_from      name of the current encoding
        v:charconvert_to        name of the desired encoding
        v:fname_in              name of the input file
        v:fname_out             name of the output file
```
Note that v:fname_in and v:fname_out will never be the same.

The advantage of using a function call without arguments is that it is faster, see expr-option-function.

If the 'charconvert' expression starts with s: or <SID>, then it is replaced with the script ID (local-function). Example:

```
set charconvert=s:MyConvert()
set charconvert=<SID>SomeConvert()
```

Otherwise the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

'chistory' 'chi' E1542 E1543

'chistory' 'chi' number (default 10)
global

Number of quickfix lists that should be remembered for the quickfix stack. Must be between 1 and 100. If the option is set to a value that is lower than the amount of entries in the quickfix list stack, entries will be removed starting from the oldest one. If the current quickfix list was removed, then the quickfix list at top of the stack (the most recently created) will be used in its place. For additional info, see quickfix-stack.

'cindent' 'cin' 'nocindent' 'nocin'

'cindent' 'cin' boolean (default off)
local to buffer

Enables automatic C program indenting. See 'cinkeys' to set the keys that trigger reindenting in insert mode and 'cinoptions' to set your preferred indent style.
If 'indentexpr' is not empty, it overrules 'cindent'.
If 'lisp' is not on and both 'indentexpr' and 'equalprg' are empty, the "=" operator indents using this algorithm rather than calling an external program.
See C-indenting.
When you don't like the way 'cindent' works, try the 'smartindent' option or 'indentexpr'.

'cinkeys' 'cink'

'cinkeys' 'cink' string (default "0{,0},0),0],:,0#,!^F,o,O,e")
local to buffer

A list of keys that, when typed in Insert mode, cause reindenting of the current line. Only used if 'cindent' is on and 'indentexpr' is empty.
For the format of this option see cinkeys-format.
See C-indenting.

'cinoptions' 'cino'

'cinoptions' 'cino' string (default "")
local to buffer

The 'cinoptions' affect the way 'cindent' reindents lines in a C program. See cinoptions-values for the values of this option, and C-indenting for info on C indenting in general.

'cinscopedecls' 'cinsd'

'cinscopedecls' 'cinsd' string (default "public,protected,private")
local to buffer

Keywords that are interpreted as a C++ scope declaration by cino-g.
Useful e.g. for working with the Qt framework that defines additional scope declarations "signals", "public slots" and "private slots":

```
set cinscopedecls+=signals,public\ slots,private\ slots
```

'cinwords' 'cinw'

'cinwords' 'cinw' string (default "if,else,while,do,for,switch")
local to buffer

These keywords start an extra indent in the next line when 'smartindent' or 'cindent' is set. For 'cindent' this is only done at an appropriate place (inside {}).
Note that 'ignorecase' isn't used for 'cinwords'. If case doesn't matter, include the keyword both the uppercase and lowercase: "if,If,IF".

'clipboard' 'cb'

'clipboard' 'cb' string (default "")
global

This option is a list of comma-separated names.
These names are recognized:

clipboard-unnamed

unnamed When included, Vim will use the clipboard register "*" for all yank, delete, change and put operations which would normally go to the unnamed register. When a register is explicitly specified, it will always be used regardless of whether "unnamed" is in 'clipboard' or not. The clipboard register can always be explicitly accessed using the "* notation. Also see clipboard.

clipboard-unnamedplus

unnamedplus A variant of the "unnamed" flag which uses the clipboard register "+" (quoteplus) instead of register "*" for all yank, delete, change and put operations which would normally go to the unnamed register. When "unnamed" is also included to the option, yank and delete operations (but not put) will additionally copy the text into register "*". See clipboard.

'cmdheight' 'ch'

'cmdheight' 'ch' number (default 1)
global or local to tabpage
Number of screen lines to use for the command-line. Helps avoiding hit-enter prompts.
The value of this option is stored with the tabpage, so that each tabpage can have a different value.

When 'cmdheight' is zero, there is no command-line unless it is being used. The command-line will cover the last line of the screen when shown.

WARNING: cmdheight=0 is EXPERIMENTAL. Works better with ui2 enabled.

'cmdwinheight' 'cwh'

'cmdwinheight' 'cwh' number (default 7)
global
Number of screen lines to use for the command-line window. cmdwin

'colorcolumn' 'cc'

'colorcolumn' 'cc' string (default "")
local to window
'colorcolumn' is a comma-separated list of screen columns that are highlighted with ColorColumn hl-ColorColumn. Useful to align text. Will make screen redrawing slower.
The screen column can be an absolute number, or a number preceded with '+' or '-', which is added to or subtracted from 'textwidth'.

```
set cc=+1         " highlight column after 'textwidth'
set cc=+1,+2,+3  " highlight three columns after 'textwidth'
hi ColorColumn ctermbg=lightgrey guibg=lightgrey
```

When 'textwidth' is zero then the items with '-' and '+' are not used.
A maximum of 256 columns are highlighted.

'columns' 'co' E594

'columns' 'co' number (default 80 or terminal width)
global
Number of columns of the screen. Normally this is set by the terminal initialization and does not have to be set by hand.
When Vim is running in the GUI or in a resizable window, setting this option will cause the window size to be changed. When you only want to use the size for the GUI, put the command in your ginit.vim file.
When you set this option and Vim is unable to change the physical number of columns of the display, the display may be messed up. For the GUI it is always possible and Vim limits the number of columns to what fits on the screen. You can use this command to get the widest window possible:

```
set columns=9999
```

Minimum value is 12, maximum value is 10000.

'comments' 'com' E524 E525

'comments' 'com' string (default "s1:/*,mb:*,ex:*/,://,b:#,:%,:XCOMM,n:>,fb:-,fb:•")
local to buffer
A comma-separated list of strings that can start a comment line. See format-comments. See option-backslash about using backslashes to insert a space.

'commentstring' 'cms' E537

'commentstring' 'cms' string (default "")
local to buffer
A template for a comment. The "%s" in the value is replaced with the comment text, and should be padded with a space when possible.
Used for commenting and to add markers for folding, see fold-marker.

'complete' 'cpt' E535

'complete' 'cpt' string (default ".,w,b,u,t")
local to buffer
This option controls how completion ins-completion behaves when using CTRL-P, CTRL-N, or ins-autocompletion. It is also used for whole-line completion i_CTRL-X_CTRL-L. It indicates the type of completion and the places to scan. It is a comma-separated list of

flags:
. scan the current buffer ('wrapscan' is ignored)
w scan buffers from other windows
b scan other loaded buffers that are in the buffer list
u scan the unloaded buffers that are in the buffer list
U scan the buffers that are not in the buffer list
k scan the files given with the 'dictionary' option
kspell use the currently active spell checking spell
k{dict} scan the file {dict}. Several "k" flags can be given, patterns are valid too. For example:

```
set cpt=k/usr/dict/*,k~/spanish
```

s scan the files given with the 'thesaurus' option
s{tsr} scan the file {tsr}. Several "s" flags can be given, patterns are valid too.
i scan current and included files
d scan current and included files for defined name or macro i_CTRL-X_CTRL-D
] tag completion
t same as "]"
f scan the buffer names (as opposed to buffer contents)
F{func} call the function {func}. Multiple "F" flags may be specified. Refer to complete-functions for details on how the function is invoked and what it should return. The value can be the name of a function or a Funcref. For Funcref values, spaces must be escaped with a backslash ('\'), and commas with double backslashes ('\\') (see option-backslash). Unlike other sources, functions can provide completions starting from a non-keyword character before the cursor, and their start position for replacing text may differ from other sources. If the Dict returned by the {func} includes {"refresh": "always"}, the function will be invoked again whenever the leading text changes.
If generating matches is potentially slow, call complete_check() periodically to keep Vim responsive. This is especially important for ins-autocompletion.
F equivalent to using "F{func}", where the function is taken from the 'completefunc' option.
o equivalent to using "F{func}", where the function is taken from the 'omnifunc' option.

Unloaded buffers are not loaded, thus their autocmds :autocmd are not executed, this may lead to unexpected completions from some files (gzipped files for example). Unloaded buffers are not scanned for whole-line completion.

CTRL-N, CTRL-P, and ins-autocompletion can be used for any 'iskeyword'-based completion (dictionary i_CTRL-X_CTRL-K, included patterns i_CTRL-X_CTRL-I, tags i_CTRL-X_CTRL-], and normal expansions). With the "F" and "o" flags in 'complete', non-keywords can also be completed.

An optional match limit can be specified for a completion source by appending a caret ("^") followed by a {count} to the source flag. For example: ".^9,w,u,t^5" limits matches from the current buffer to 9 and from tags to 5. Other sources remain unlimited.
Note: The match limit takes effect only during forward completion (CTRL-N) and is ignored during backward completion (CTRL-P).

This option cannot be set in a modeline when 'modelineexpr' is off.

'completefunc' 'cfu'
'completefunc' 'cfu' string (default "")
local to buffer
Disallowed in modeline. no-modeline-option
This option specifies a function to be used for Insert mode completion with CTRL-X CTRL-U. i_CTRL-X_CTRL-U
See complete-functions for an explanation of how the function is invoked and what it should return. The value can be the name of a function, a lambda or a Funcref. See option-value-function for more information.

'completeitemalign' 'cia'
'completeitemalign' 'cia' string (default "abbr,kind,menu")
global
A comma-separated list of strings that controls the alignment and display order of items in the popup menu during Insert mode completion. The supported values are "abbr", "kind", and "menu". These values allow customizing how complete-items are shown in the popup menu. **Note:** must always contain those three values in any order.

'completeopt' 'cot'
'completeopt' 'cot' string (default "menu,popup")
global or local to buffer global-local
A comma-separated list of options for Insert mode completion ins-completion. The supported values are:

fuzzy Enable fuzzy-matching for completion candidates. This allows for more flexible and intuitive matching, where characters can be skipped and matches can be found even if the exact sequence is not typed (disabled for thesaurus completion compl-thesaurus).

longest
When 'autocomplete' is not active, only the longest common prefix of the matches is inserted (disabled for thesaurus completion compl-thesaurus). If the popup menu is displayed, you can use CTRL-L to add more characters. Whether case is ignored depends on the type of completion. For buffer text the 'ignorecase' option applies.

When 'autocomplete' is active and no completion item is selected, the longest common prefix of the matches is inserted after the cursor. The prefix is taken either from all displayed items or only from items in the current buffer. The inserted text is highlighted with hl-PreInsert, and the cursor position does not change (similar to "preinsert"). Press CTRL-Y to accept. See also preinserted().

menu Use a popup menu to show the possible completions. The menu is only shown when there is more than one match. ins-completion-menu

menuone Use the popup menu also when there is only one match. Useful when there is additional information about the match, e.g., what file it comes from.

nearest Matches are listed based on their proximity to the cursor position, unlike the default behavior, which only considers proximity for matches appearing below the cursor. This applies only to matches from the current buffer. No effect if "fuzzy" is present.

noinsert Do not insert any text for a match until the user selects a match from the menu. Only works in combination with "menu" or "menuone". No effect if "longest" is present.

noselect Same as "noinsert", except that no menu item is pre-selected. Takes precedence over "noinsert". Enabled automatically when 'autocomplete' is on, unless "preinsert" is also enabled.

nosort Disable sorting of completion candidates based on fuzzy scores when "fuzzy" is enabled. Candidates will appear in their original order.

popup Show extra information about the currently selected completion in a popup window. Only works in combination with "menu" or "menuone". Overrides "preview".

preinsert
Inserts the text of the first completion candidate beyond the current leader, highlighted with hl-PreInsert.
The cursor does not move.
Requires "fuzzy" to be unset, and either "menuone" in 'completeopt' or 'autocomplete' enabled. When 'autocomplete' is enabled, this does not work if 'ignorecase' is set without 'infercase'.
See also preinserted().

preselect
When one of complete-items has its "preselect" field set (e.g., as indicated by an LSP server), select the first such item in the popupmenu-completion. Takes precedence over "noselect".

Unlike the implicit selection behavior (when "noselect" is not set), this preserves the original sort order and navigates to the preselect item rather than always selecting the first item.

preview Show extra information about the currently selected completion in the preview window. Only works in combination with "menu" or "menuone".

Only "fuzzy", "longest", "popup", "preinsert", "preselect" and "preview" have an effect when 'autocomplete' is enabled.

This option does not apply to cmdline-completion. See 'wildoptions' for that.

'completeslash' 'csl'
'completeslash' 'csl' string (default "")
local to buffer
only modifiable in MS-Windows

When this option is set it overrules 'shellslash' for completion:

- When this option is set to "slash", a forward slash is used for path completion in insert mode. This is useful when editing HTML tag, or Makefile with 'noshellslash' on MS-Windows.
- When this option is set to "backslash", backslash is used. This is useful when editing a batch file with 'shellslash' set on MS-Windows.
- When this option is empty, same character is used as for 'shellslash'.

For Insert mode completion the buffer-local value is used. For
command line completion the global value is used.

'completetimeout' 'cto'
'completetimeout' 'cto' number (default 0)
global
Like 'autocompletetimeout', but applies to i_CTRL-N and i_CTRL-P
completion. Value of 0 disables the timeout; positive values allowed.

'concealcursor' 'cocu'
'concealcursor' 'cocu' string (default "")
local to window
Sets the modes in which text in the cursor line can also be concealed.
When the current mode is listed then concealing happens just like in
other lines.

n	Normal mode
v	Visual mode
i	Insert mode
c	Command line editing, for 'incsearch'

'v' applies to all lines in the Visual area, not only the cursor.
A useful value is "nc". This is used in help files. So long as you
are moving around text is concealed, but when starting to insert text
or selecting a Visual area the concealed text is displayed, so that
you can see what you are doing.
Keep in mind that the cursor position is not always where it's
displayed. E.g., when moving vertically it may change column.

'conceallevel' 'cole'
'conceallevel' 'cole' number (default 0)
local to window
Determine how text with the "conceal" syntax attribute :syn-conceal
is shown:

Value	Effect
0	Text is shown normally
1	Each block of concealed text is replaced with one character. If the syntax item does not have a custom replacement character defined (see :syn-cchar) the character defined in 'listchars' is used. It is highlighted with the "Conceal" highlight group.
2	Concealed text is completely hidden unless it has a custom replacement character defined (see :syn-cchar).
3	Concealed text is completely hidden.

Note: in the cursor line concealed text is not hidden, so that you can
edit and copy the text. This can be changed with the 'concealcursor'
option.

'confirm' 'cf' 'noconfirm' 'nocf'
'confirm' 'cf' boolean (default off)
global
When 'confirm' is on, certain operations that would normally
fail because of unsaved changes to a buffer, e.g. ":q" and ":e",
instead raise a dialog asking if you wish to save the current
file(s). You can still use a ! to unconditionally abandon a buffer.
If 'confirm' is off you can still activate confirmation for one
command only (this is most useful in mappings) with the :confirm
command.
Also see the confirm() function and the 'v' flag in 'guioptions'.

'copyindent' 'ci' 'nocopyindent' 'noci'
'copyindent' 'ci' boolean (default off)
local to buffer
Copy the structure of the existing lines indent when autoindenting a
new line. Normally the new indent is reconstructed by a series of
tabs followed by spaces as required (unless 'expandtab' is enabled,
in which case only spaces are used). Enabling this option makes the
new line copy whatever characters were used for indenting on the
existing line. 'expandtab' has no effect on these characters, a Tab
remains a Tab. If the new indent is greater than on the existing
line, the remaining space is filled in the normal manner.
See 'preserveindent'.

'cpoptions' 'cpo' cpo
'cpoptions' 'cpo' string (default "aABceFs_")
global
A sequence of single character flags. When a character is present
this indicates Vi-compatible behavior. This is used for things where
not being Vi-compatible is mostly or sometimes preferred.
'cpoptions' stands for "compatible-options".
Commas can be added for readability.
To avoid problems with flags that are added in the future, use the
"+=" and "-=" feature of ":set" add-option-flags.

contains	behavior	
cpo-a		
a	When included, a ":read" command with a file name argument will set the alternate file name for the current window. cpo-A	
A	When included, a ":write" command with a file name argument will set the alternate file name for the current window. cpo-b	
b	"|" in a ":map" command is recognized as the end of the map command. The '\' is included in the mapping, the text after the '|' is interpreted as the next command. Use a CTRL-V instead of a backslash to include the '|' in the mapping. Applies to all mapping, abbreviation, menu and autocmd commands. See also map_bar. cpo-B	
B	A backslash has no special meaning in mappings, abbreviations, user commands and the "to" part of the menu commands. Remove this flag to be able to use a backslash like a CTRL-V. For example, the command ":map X \ <Esc>" results in X being mapped to:	
'B' included:	"\^["	(^[is a real <Esc>)
'B' excluded:	"<Esc>" (5 characters) cpo-c	
c	Searching continues at the end of any match at the cursor position, but not further than the start of the next line. When not present searching continues one character from the cursor position. With 'c' "abababababab" only gets three matches when repeating "/abab", without 'c' there are five matches. cpo-C	
C	Do not concatenate sourced lines that start with a backslash. See line-continuation. cpo-d	
d	Using "./" in the 'tags' option doesn't mean to use the tags file relative to the current file, but the tags file in the current directory. cpo-D	
D	Can't use CTRL-K to enter a digraph after Normal mode commands with a character argument, like r, f and t. cpo-e	
e	When executing a register with ":@r", always add a <CR> to the last line, also when the register is not linewise. If this flag is not present, the register is not linewise and the last line does not end in a <CR>, then the last line is put on the command-line and can be edited before hitting <CR>. cpo-E	
E	It is an error when using "y", "d", "c", "g~", "gu" or "gU" on an Empty region. The operators only work when at least one character is to be operated on. Example: This makes "y0" fail in the first column. cpo-f	
f	When included, a ":read" command with a file name argument will set the file name for the current buffer, if the current buffer doesn't have a file name yet. cpo-F	
F	When included, a ":write" command with a file name argument will set the file name for the current buffer, if the current buffer doesn't have a file name yet. Also see cpo-P. cpo-i	
i	When included, interrupting the reading of a file will leave it modified. cpo-I	
I	When moving the cursor up or down just after inserting indent for 'autoindent', do not delete the indent. cpo-J	
J	A sentence has to be followed by two spaces after the '.', '!' or '?'. A <Tab> is not recognized as white space. cpo-K	
K	Don't wait for a key code to complete when it is halfway through a mapping. This breaks mapping <F1><F1> when only part of the second <F1> has been read. It enables cancelling the mapping by typing <F1><Esc>. cpo-l	
l	Backslash in a [] range in a search pattern is taken literally, only "\]", "\^", "\-" and "\\" are special. See /[] 'l' included: "/[\t]" finds <Space>, '\' and 't' 'l' excluded: "/[\t]" finds <Space> and <Tab> cpo-L	
L	When the 'list' option is set, 'wrapmargin', 'textwidth', 'softtabstop' and Virtual Replace mode (see gR) count a <Tab> as two characters, instead of the normal behavior of a <Tab>. cpo-m	
m	When included, a showmatch will always wait half a second. When not included, a showmatch will wait half a second or until a character is typed. 'showmatch' cpo-M	
M	When excluded, "%" matching will take backslashes into account. Thus in "(\( )" and "\((\)" the outer parenthesis match. When included "%" ignores backslashes, which is Vi compatible. cpo-n	
n	When included, the column used for 'number' and 'relativenumber' will also be used for text of wrapped lines. cpo-o	
o	Line offset to search command is not remembered for next search. cpo-O	
O	Don't complain if a file is being overwritten, even when it didn't exist when editing it. This is a protection against a file unexpectedly created by someone else. Vi didn't complain about this. cpo-P	
P	When included, a ":write" command that appends to a file will set the file name for the current buffer, if the current buffer doesn't have a file name yet and the 'F' flag is also included cpo-F. cpo-q	
q	When joining multiple lines leave the cursor at the position where it would be when joining two lines. cpo-r	
r	Redo ("." command) uses "/" to repeat a search command, instead of the actually used search string. cpo-R	
R	Remove marks from filtered lines. Without this flag marks are kept like :keepmarks was used. cpo-s	
s	Set buffer options when entering the buffer for the first time. This is like it is in Vim version 3.0. And it is the default. If not present the options are set when the buffer is created. cpo-S	
S	Set buffer options always when entering a buffer (except 'readonly', 'fileformat', 'filetype' and 'syntax'). This is the (most) Vi compatible setting. The options are set to the values in the current buffer. When you change an option and go to another buffer, the value is copied. Effectively makes the buffer options global to all buffers.	

```
's'     'S'     copy buffer options
no      no      when buffer created
yes     no      when buffer first entered (default)
 X      yes     each time when buffer entered (vi comp.)
```

cpo-t

t	Search pattern for the tag command is remembered for
	"n" command. Otherwise Vim only puts the pattern in
	the history for search pattern, but doesn't change the
	last used search pattern.

cpo-u

u	Undo is Vi compatible. See undo-two-ways.

cpo-v

v	Backspaced characters remain visible on the screen in
	Insert mode. Without this flag the characters are
	erased from the screen right away. With this flag the
	screen newly typed text overwrites backspaced
	characters.

cpo-W

W	Don't overwrite a readonly file. When omitted, ":w!"
	overwrites a readonly file, if possible.

cpo-x

x	<Esc> on the command-line executes the command-line.
	The default in Vim is to abandon the command-line,
	because <Esc> normally aborts a command. c_<Esc>

cpo-X

X	When using a count with "R" the replaced text is
	deleted only once. Also when repeating "R" with "."
	and a count.

cpo-y

y	A yank command can be redone with ".". Think twice if
	you really want to use this, it may break some
	plugins, since most people expect "." to only repeat a
	change.

cpo-Z

Z	When using "w!" while the 'readonly' option is set,
	don't reset 'readonly'.

cpo-!

!	When redoing a filter command, use the last used
	external command, whatever it was. Otherwise the last
	used -filter- command is used.

cpo-$

$	When making a change to one line, don't redisplay the
	line, but put a '$' at the end of the changed text.
	The changed text will be overwritten when you type the
	new text. The line is redisplayed if you type any
	command that moves the cursor from the insertion
	point.

cpo-%

%	Vi-compatible matching is done for the "%" command.
	Does not recognize "#if", "#endif", etc.
	Does not recognize "/*" and "*/".
	Parens inside single and double quotes are also
	counted, causing a string that contains a paren to
	disturb the matching. For example, in a line like
	"if (strcmp("foo(", s))" the first paren does not
	match the last one. When this flag is not included,
	parens inside single and double quotes are treated
	specially. When matching a paren outside of quotes,
	everything inside quotes is ignored. When matching a
	paren inside quotes, it will find the matching one (if
	there is one). This works very well for C programs.
	This flag is also used for other features, such as
	C-indenting.

cpo-+

+	When included, a ":write file" command will reset the
	'modified' flag of the buffer, even though the buffer
	itself may still be different from its file.

cpo->

>	When appending to a register, put a line break before
	the appended text.

cpo-;

;	When using , or ; to repeat the last t search
	and the cursor is right in front of the searched
	character, the cursor won't move. When not included,
	the cursor would skip over it and jump to the
	following occurrence.

cpo-~

~	When included, don't resolve symbolic links when
	changing directory with :cd, :tcd, :lcd, or :bcd.
	This preserves the symbolic link path in buffer names
	and when displaying the current directory. When

excluded (default), symbolic links are resolved to
their target paths.

'cpo-_'

_ When using cw on a word, do not include the
whitespace following the word in the motion.

'cursorbind' 'crb' 'nocursorbind' 'nocrb'
'cursorbind' 'crb' boolean (default off)
local to window
When this option is set, as the cursor in the current
window moves other cursorbound windows (windows that also have
this option set) move their cursors to the corresponding line and
column. This option is useful for viewing the
differences between two versions of a file (see 'diff'); in diff mode,
inserted and deleted lines (though not characters within a line) are
taken into account.

'cursorcolumn' 'cuc' 'nocursorcolumn' 'nocuc'
'cursorcolumn' 'cuc' boolean (default off)
local to window
Highlight the screen column of the cursor with CursorColumn
hl-CursorColumn. Useful to align text. Will make screen redrawing
slower.
If you only want the highlighting in the current window you can use
these autocommands:

```
au WinLeave * set nocursorline nocursorcolumn
au WinEnter * set cursorline cursorcolumn
```

'cursorline' 'cul' 'nocursorline' 'nocul'
'cursorline' 'cul' boolean (default off)
local to window
Highlighting used for the line the cursor is on:

CursorLine the text line hl-CursorLine
CursorLineFold the fold column hl-CursorLineFold
CursorLineSign the sign column hl-CursorLineSign
CursorLineNr the line number, when 'cursorlineopt' contains
"number" hl-CursorLineNr

Useful to easily spot the cursor. Will make screen redrawing slower.
When Visual mode is active the highlighting isn't used to make it
easier to see the selected text.

'cursorlineopt' 'culopt'
'cursorlineopt' 'culopt' string (default "both")
local to window
Comma-separated list of settings for how 'cursorline' is displayed.
Valid values:
"line" Highlight the text line of the cursor with
CursorLine hl-CursorLine.
"screenline" Highlight only the screen line of the cursor with
CursorLine hl-CursorLine.
"number" Highlight the line number of the cursor with
CursorLineNr hl-CursorLineNr.

Special value:
"both" Alias for the values "line,number".

"line" and "screenline" cannot be used together.

'debug'

'debug' string (default "")
global
These values can be used:
msg Error messages that would otherwise be omitted will be given
anyway.
throw Error messages that would otherwise be omitted will be given
anyway and also throw an exception and set v:errmsg.
beep A message will be given when otherwise only a beep would be
produced.
The values can be combined, separated by a comma.
"msg" and "throw" are useful for debugging 'foldexpr', 'formatexpr' or
'indentexpr'.

'define' 'def'
'define' 'def' string (default "")
global or local to buffer global-local
Pattern to be used to find a macro definition. It is a search
pattern, just like for the "/" command. This option is used for the
commands like "[i" and "[d" include-search. The 'isident' option is
used to recognize the defined name after the match:

```
{match with 'define'}{non-ID chars}{defined name}{non-ID char}
```

See option-backslash about inserting backslashes to include a space
or backslash.
For C++ this value would be useful, to include const type declarations:

```
^\(#\s*define\|[a-z]*\s*const\s*[a-z]*\)
```

You can also use "\ze" just before the name and continue the pattern
to check what is following. E.g. for Javascript, if a function is

defined with func_name = function(args):

```
^\s*\ze\i\+\s*=\s*function(
```

If the function is defined with func_name : function() {...:

```
^\s*\ze\i\+\s*[:]\s*(*function\s*(
```

When using the ":set" command, you need to double the backslashes!
To avoid that use :let with a single quote string:

```
let &l:define = '^\s*\ze\k\+\s*=\s*function('
```

'delcombine' 'deco' 'nodelcombine' 'nodeco'
'delcombine' 'deco' boolean (default off)
global
If editing Unicode and this option is set, backspace and Normal mode "x" delete each combining character on its own. When it is off (the default) the character along with its combining characters are deleted.
Note: When 'delcombine' is set "xx" may work differently from "2x"!

This is useful for Arabic, Hebrew and many other languages where one may have combining characters overtop of base characters, and want to remove only the combining ones.

'dictionary' 'dict'
'dictionary' 'dict' string (default "")
global or local to buffer global-local
List of file names, separated by commas, that are used to lookup words for keyword completion commands i_CTRL-X_CTRL-K. Each file should contain a list of words. This can be one word per line, or several words per line, separated by non-keyword characters (white space is preferred). Maximum line length is 510 bytes.

When this option is empty or an entry "spell" is present, and spell checking is enabled, words in the word lists for the currently active 'spelllang' are used. See spell.

To include a comma in a file name precede it with a backslash. Spaces after a comma are ignored, otherwise spaces are included in the file name. See option-backslash about using backslashes.
Environment variables are expanded :set_env.
This has nothing to do with the Dictionary variable type.
Where to find a list of words?

- BSD/macOS include the "/usr/share/dict/words" file.

- Try "apt install spell" to get the "/usr/share/dict/words" file on

apt-managed systems (Debian/Ubuntu).
The use of :set+= and :set-= is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default.
Backticks cannot be used in this option for security reasons.

'diff' 'nodiff'
'diff' boolean (default off)
local to window
Join the current window in the group of windows that shows differences between files. See diff-mode.

'diffanchors' 'dia'
'diffanchors' 'dia' string (default "")
global or local to buffer global-local
List of {address} in each buffer, separated by commas, that are considered anchors when used for diffing. It's valid to specify "$+1" for 1 past the last line. "%" cannot be used for this option. There can be at most 20 anchors set for each buffer.

Each anchor line splits the buffer (the split happens above the anchor), with each part being diff'ed separately before the final result is joined. When more than one {address} are provided, the anchors will be sorted internally by line number. If using buffer local options, each buffer should have the same number of anchors (extra anchors will be ignored). This option is only used when 'diffopt' has "anchor" set. See diff-anchors for more details and examples.

E1550

If some of the {address} do not resolve to a line in each buffer (e.g. a pattern search that does not match anything), none of the anchors will be used.

E1562

Diff anchors can only be used when there are no hidden diff buffers.

'diffexpr' 'dex'
'diffexpr' 'dex' string (default "")
global
Disallowed in modeline. no-modeline-option
Expression which is evaluated to obtain a diff file (either ed-style or unified-style) from two versions of a file. See diff-diffexpr.

'diffopt' 'dip'	string	(default "internal,filler,closeoff,indent-heuristic,inline:char,linematch:40")
		global

Option settings for diff mode. It can consist of the following items.
All are optional. Items must be separated by a comma.

algorithm:{text} Use the specified diff algorithm with the internal diff engine. Currently supported algorithms are:

myers	the default algorithm
minimal	spend extra time to generate the smallest possible diff
patience	patience diff algorithm
histogram	histogram diff algorithm

anchor Anchor specific lines in each buffer to be aligned with each other if 'diffanchors' is set. See diff-anchors.

closeoff When a window is closed where 'diff' is set and there is only one window remaining in the same tabpage with 'diff' set, execute :diffoff in that window. This undoes a :diffsplit command.

context:{n} Use a context of {n} lines between a change and a fold that contains unchanged lines. When omitted a context of six lines is used. When using zero the context is actually one, since folds require a line in between, also for a deleted line. Set it to a very large value (999999) to disable folding completely. See fold-diff.

filler Show filler lines, to keep the text synchronized with a window that has inserted lines at the same position. Mostly useful when windows are side-by-side and 'scrollbind' is set.

foldcolumn:{n} Set the 'foldcolumn' option to {n} when starting diff mode. Without this 2 is used.

followwrap Follow the 'wrap' option and leave as it is.

horizontal Start diff mode with horizontal splits (unless explicitly specified otherwise).

hiddenoff Do not use diff mode for a buffer when it becomes hidden.

iblank Ignore changes where lines are all blank. Adds the "-B" flag to the "diff" command if 'diffexpr' is empty. Check the documentation of the "diff" command for what this does exactly.
NOTE: the diff windows will get out of sync, because no differences between blank lines are taken into account.

icase Ignore changes in case of text. "a" and "A" are considered the same. Adds the "-i" flag to the "diff" command if 'diffexpr' is empty.

indent-heuristic
Use the indent heuristic for the internal diff library.

inline:{text} Highlight inline differences within a change. See view-diffs. Supported values are:

none	Do not perform inline highlighting.
simple	Highlight from first different character to the last one in each line. This is the default if no inline: value is set.
char	Use internal diff to perform a character-wise diff and highlight the difference.
word	Use internal diff to perform a word-wise diff and highlight the difference. Non-alphanumeric multi-byte characters such as emoji and CJK characters are considered individual words. Small gaps of non-word characters (5 bytes or less) between changes are merged into a single highlight block.

internal Use the internal diff library. This is ignored when 'diffexpr' is set. E960
When running out of memory when writing a buffer or the diff is larger than 1 GB this item will be ignored for diffs involving that buffer. Set the 'verbose' option to see when this happens.

iwhite Ignore changes in amount of white space. Adds the "-b" flag to the "diff" command if

'diffexpr' is empty. Check the documentation
of the "diff" command for what this does
exactly. It should ignore adding trailing
white space, but not leading white space.

iwhiteall Ignore all white space changes. Adds the "-w" flag to the "diff" command if 'diffexpr' is empty. Check the documentation of the "diff" command for what this does exactly.

iwhiteeol Ignore white space changes at end of line. Adds the "-Z" flag to the "diff" command if 'diffexpr' is empty. Check the documentation of the "diff" command for what this does exactly.

linematch:{n} Align and mark changes between the most similar lines between the buffers. When the total number of lines in the diff hunk exceeds {n}, the lines will not be aligned because for very large diff hunks there will be a noticeable lag. A reasonable setting is "linematch:60", as this will enable alignment for a 2 buffer diff hunk of 30 lines each, or a 3 buffer diff hunk of 20 lines each. Implicitly sets "filler" when this is set.

vertical Start diff mode with vertical splits (unless explicitly specified otherwise).

Examples:

```
set diffopt=internal,filler,context:4
set diffopt=
set diffopt=internal,filler,foldcolumn:3
set diffopt-=internal  " do NOT use the internal diff parser
```

'digraph' 'dg' 'nodigraph' 'nodg'

'digraph' 'dg' boolean (default off)
global

Enable the entering of digraphs in Insert mode with {char1} <BS> {char2}. See digraphs.

'directory' 'dir'

'directory' 'dir' string (default "$XDG_STATE_HOME/nvim/swap//")
global
Disallowed in modeline. no-modeline-option

List of directory names for the swap file, separated with commas.

Possible items:

- The swap file will be created in the first directory where this is possible. If it is not possible in any directory, but last directory listed in the option does not exist, it is created.
- Empty means that no swap file will be used (recovery is impossible!) and no E303 error will be given.
- A directory "." means to put the swap file in the same directory as the edited file. On Unix, a dot is prepended to the file name, so it doesn't show in a directory listing. On MS-Windows the "hidden" attribute is set and a dot prepended if possible.
- A directory starting with "./" (or ".\" for MS-Windows) means to put the swap file relative to where the edited file is. The leading "." is replaced with the path name of the edited file.
- For Unix and Win32, if a directory ends in two path separators "//", the swap file name will be built from the complete path to the file with all path separators replaced by percent '%' signs (including the colon following the drive letter on Win32). This will ensure file name uniqueness in the preserve directory.
  On Win32, it is also possible to end with "\\". However, When a separating comma is following, you must use "//", since "\\" will include the comma in the file name. Therefore it is recommended to use '//', instead of '\\'.
- Spaces after the comma are ignored, other spaces are considered part of the directory name. To have a space at the start of a directory name, precede it with a backslash.
- To include a comma in a directory name precede it with a backslash.
- A directory name may end in an ':' or '/'.

- Environment variables are expanded :set_env.

- Careful with '\' characters, type one before a space, type two to

  get one in the option (see option-backslash), for example:

```
set dir=c:\\tmp,\ dir\\,with\\,commas,\\\ dir\ with\ spaces
```

Editing the same file twice will result in a warning. Using "/tmp" on is discouraged: if the system crashes you lose the swap file. And others on the computer may be able to see the files.
Use :set+= and :set-= when adding or removing directories from the list, this avoids problems if the Nvim default is changed.

'display' 'dy'

'display' 'dy' string (default "lastline")
global
Change the way text is displayed. This is a comma-separated list of flags:
lastline When included, as much as possible of the last line in a window will be displayed. "@@@" is put in the last columns of the last screen line to indicate the rest of the line is not displayed.
truncate Like "lastline", but "@@@" is displayed in the first column of the last screen line. Overrules "lastline".
uhex Show unprintable characters hexadecimal as <xx> instead of using ^C and ~C.
msgsep Obsolete flag. Allowed but takes no effect. msgsep

When neither "lastline" nor "truncate" is included, a last line that doesn't fit is replaced with "@" lines.

The "@" character can be changed by setting the "lastline" item in 'fillchars'. The character is highlighted with hl-NonText.

'eadirection' 'ead'

'eadirection' 'ead' string (default "both")
global
Tells when the 'equalalways' option applies:
ver vertically, width of windows is not affected
hor horizontally, height of windows is not affected
both width and height of windows is affected

'emoji' 'emo' 'noemoji' 'noemo'

'emoji' 'emo' boolean (default on)
global
When on all Unicode emoji characters are considered to be full width. This excludes "text emoji" characters, which are normally displayed as single width. However, such "text emoji" are treated as full-width emoji if they are followed by the U+FE0F variant selector.

Unfortunately there is no good specification for this and it has been determined on trial-and-error basis. Use the setcellwidths() function to change the behavior.

'encoding' 'enc'

'encoding' 'enc' string (default "utf-8")
global
String-encoding used internally and for RPC communication.
Always UTF-8.

See 'fileencoding' to control file-content encoding.

'endoffile' 'eof' 'noendoffile' 'noeof'

'endoffile' 'eof' boolean (default off)
local to buffer
Indicates that a CTRL-Z character was found at the end of the file when reading it. Normally only happens when 'fileformat' is "dos".
When writing a file and this option is off and the 'binary' option is on, or 'fixeol' option is off, no CTRL-Z will be written at the end of the file.
See eol-and-eof for example settings.

'endofline' 'eol' 'noendofline' 'noeol'

'endofline' 'eol' boolean (default on)
local to buffer
When writing a file and this option is off and the 'binary' option is on, or 'fixeol' option is off, no <EOL> will be written for the last line in the file. This option is automatically set or reset when starting to edit a new file, depending on whether file has an <EOL> for the last line in the file. Normally you don't have to set or reset this option.
When 'binary' is off and 'fixeol' is on the value is not used when writing the file. When 'binary' is on or 'fixeol' is off it is used to remember the presence of a <EOL> for the last line in the file, so that when you write the file the situation from the original file can be kept. But you can change it if you want to.
See eol-and-eof for example settings.

'equalalways' 'ea' 'noequalalways' 'noea'

'equalalways' 'ea' boolean (default on)
global
When on, all the windows are automatically made the same size after

splitting or closing a window. This also happens the moment the option is switched on. When off, splitting a window will reduce the size of the current window and leave the other windows the same. When closing a window the extra lines are given to the window next to it (depending on 'splitbelow' and 'splitright').
When mixing vertically and horizontally split windows, a minimal size is computed and some windows may be larger if there is room. The 'eadirection' option tells in which direction the size is affected. Changing the height and width of a window can be avoided by setting 'winfixheight' and 'winfixwidth', respectively.
If a window size is specified when creating a new window sizes are currently not equalized (it's complicated, but may be implemented in the future).

'equalprg' 'ep'
'equalprg' 'ep' string (default "")
global or local to buffer global-local
Disallowed in modeline. no-modeline-option
External program to use for "=" command. When this option is empty the internal formatting functions are used; either 'lisp', 'cindent' or 'indentexpr'.
Environment variables are expanded :set_env. See option-backslash about including spaces and backslashes.

'errorbells' 'eb' 'noerrorbells' 'noeb'
'errorbells' 'eb' boolean (default off)
global
Ring the bell (beep or screen flash) for error messages. This only makes a difference for error messages, the bell will be used always for a lot of errors without a message (e.g., hitting <Esc> in Normal mode). See 'visualbell' to make the bell behave like a screen flash or do nothing. See 'belloff' to finetune when to ring the bell.

'errorfile' 'ef'
'errorfile' 'ef' string (default "errors.err")
global
Disallowed in modeline. no-modeline-option
Name of the errorfile for the QuickFix mode (see :cf).
When the "-q" command-line argument is used, 'errorfile' is set to the following argument. See -q.
NOT used for the ":make" command. See 'makeef' for that.
Environment variables are expanded :set_env.
See option-backslash about including spaces and backslashes.

'errorformat' 'efm'
'errorformat' 'efm' string (default is very long)
global or local to buffer global-local
Scanf-like description of the format for the lines in the error file (see errorformat).

'eventignore' 'ei'
'eventignore' 'ei' string (default "")
global
A list of autocommand event names, which are to be ignored.
When set to "all" or when "all" is one of the items, all autocommand events are ignored, autocommands will not be executed.
Otherwise this is a comma-separated list of event names. Example:

```
set ei=WinEnter,WinLeave
```

To ignore all but some events, a "-" prefix can be used:

```
:set ei=all,-WinLeave
```

'eventignorewin' 'eiw'
'eventignorewin' 'eiw' string (default "")
local to window
Similar to 'eventignore' but applies to a particular window and its buffers, for which window and buffer related autocommands can be ignored indefinitely without affecting the global 'eventignore'.

Note: The following events are considered to happen outside of a window context and thus cannot be ignored by 'eventignorewin':

ChanClose,
ChanInfo,

'expandtab' 'et' 'noexpandtab' 'noet'
'expandtab' 'et' boolean (default off)
local to buffer

In Insert mode: Use the appropriate number of spaces to insert a <Tab>. Spaces are used in indents with the '>' and '<' commands and when 'autoindent' is on. To insert a real tab when 'expandtab' is on, use CTRL-V<Tab>. See also :retab and ins-expandtab.

'exrc' 'ex' 'noexrc' 'noex' project-config workspace-config
'exrc' 'ex' boolean (default off)
global
Disallowed in modeline. no-modeline-option

Enables project-local configuration. Nvim will execute any .nvim.lua, .nvimrc, or .exrc file found in the current-directory and all parent directories (ordered upwards), if the files are in the trust list. Use :trust to manage trusted files. See also vim.secure.read().

Unset 'exrc' to stop further searching of 'exrc' files in parent directories, similar to editorconfig.root.

To get its own location, a Lua exrc file can use debug.getinfo(). See lua-script-location.

Compare 'exrc' to editorconfig:

- 'exrc' can execute any code; editorconfig only specifies settings.
- 'exrc' is Nvim-specific; editorconfig works in other editors.

To achieve project-local LSP configuration:

1. Enable 'exrc'.

2. Place LSP configs at ".nvim/lsp/*.lua" in your project root.

3. Create ".nvim.lua" in your project root directory with this line:

```
vim.cmd[[set runtimepath+=.nvim]]
```

'fileencoding' 'fenc' E213

'fileencoding' 'fenc' string (default "")
local to buffer

File-content encoding for the current buffer. Conversion is done with iconv() or as specified with 'charconvert'.

When 'fileencoding' is not UTF-8, conversion will be done when writing the file. For reading see below.
When 'fileencoding' is empty, the file will be saved with UTF-8 encoding (no conversion when reading or writing a file).

WARNING: Conversion to a non-Unicode encoding can cause loss of information!

See encoding-names for the possible values. Additionally, values may be specified that can be handled by the converter, see mbyte-conversion.

When reading a file 'fileencoding' will be set from 'fileencodings'. To read a file in a certain encoding it won't work by setting 'fileencoding', use the ++enc argument. One exception: when 'fileencodings' is empty the value of 'fileencoding' is used. For a new file the global value of 'fileencoding' is used.

Prepending "8bit-" and "2byte-" has no meaning here, they are ignored. When the option is set, the value is converted to lowercase. Thus you can set it with uppercase values too. '_' characters are replaced with '-'. If a name is recognized from the list at encoding-names, it is replaced by the standard name. For example "ISO8859-2" becomes "iso-8859-2".

When this option is set, after starting to edit a file, the 'modified' option is set, because the file would be different when written.

Keep in mind that changing 'fenc' from a modeline happens AFTER the text has been read, thus it applies to when the file will be written. If you do set 'fenc' in a modeline, you might want to set 'nomodified' to avoid not being able to ":q".

This option cannot be changed when 'modifiable' is off.

'fileencodings' 'fencs'

'fileencodings' 'fencs' string (default "ucs-bom,utf-8,default,latin1")
global

This is a list of character encodings considered when starting to edit an existing file. When a file is read, Vim tries to use the first mentioned character encoding. If an error is detected, the next one in the list is tried. When an encoding is found that works, 'fileencoding' is set to it. If all fail, 'fileencoding' is set to an empty string, which means that UTF-8 is used.

WARNING: Conversion can cause loss of information! You can use the ++bad argument to specify what is done with characters that can't be converted.

For an empty file or a file with only ASCII characters most encodings will work and the first entry of 'fileencodings' will be used (except "ucs-bom", which requires the BOM to be present). If you prefer another encoding use an BufReadPost autocommand event to test if your preferred encoding is to be used. Example:

```
au BufReadPost * if search('\S', 'w') == 0 |
        \ set fenc=iso-2022-jp | endif
```

This sets 'fileencoding' to "iso-2022-jp" if the file does not contain non-blank characters.
When the ++enc argument is used then the value of 'fileencodings' is not used.
Note that 'fileencodings' is not used for a new file, the global value of 'fileencoding' is used instead. You can set it with:

```
setglobal fenc=iso-8859-2
```

This means that a non-existing file may get a different encoding than an empty file.
The special value "ucs-bom" can be used to check for a Unicode BOM (Byte Order Mark) at the start of the file. It must not be preceded by "utf-8" or another Unicode encoding for this to work properly.
An entry for an 8-bit encoding (e.g., "latin1") should be the last, because Vim cannot detect an error, thus the encoding is always accepted.
The special value "default" can be used for the encoding from the environment. It is useful when your environment uses a non-latin1 encoding, such as Russian.
When a file contains an illegal UTF-8 byte sequence it won't be recognized as "utf-8". You can use the 8g8 command to find the illegal byte sequence.

WRONG VALUES:	WHAT'S WRONG:
latin1,utf-8	"latin1" will always be used
utf-8,ucs-bom,latin1	BOM won't be recognized in a utf-8 file
cp1250,latin1	"cp1250" will always be used

If 'fileencodings' is empty, 'fileencoding' is not modified.
See 'fileencoding' for the possible values.
Setting this option does not have an effect until the next time a file is read.

'fileformat' 'ff'

'fileformat' 'ff' string (default Windows: "dos", Unix: "unix")
local to buffer

This gives the <EOL> of the current buffer, which is used for reading/writing the buffer from/to a file:

dos	<CR><NL>
unix	<NL>
mac	<CR>

When "dos" is used, CTRL-Z at the end of a file is ignored.
See file-formats and file-read.
For the character encoding of the file see 'fileencoding'.
When 'binary' is set, the value of 'fileformat' is ignored, file I/O works like it was set to "unix".
This option is set automatically when starting to edit a file and 'fileformats' is not empty and 'binary' is off.
When this option is set, after starting to edit a file, the 'modified' option is set, because the file would be different when written.
This option cannot be changed when 'modifiable' is off.

'fileformats' 'ffs'

'fileformats' 'ffs' string (default Windows: "dos,unix", Unix: "unix,dos")
global

This gives the end-of-line (<EOL>) formats that will be tried when starting to edit a new buffer and when reading a file into an existing buffer:

- When empty, the format defined with 'fileformat' will be used always. It is not set automatically.
- When set to one name, that format will be used whenever a new buffer is opened. 'fileformat' is set accordingly for that buffer. The 'fileformats' name will be used when a file is read into an existing buffer, no matter what 'fileformat' for that buffer is set to.
- When more than one name is present, separated by commas, automatic <EOL> detection will be done when reading a file. When starting to edit a file, a check is done for the <EOL>:
  1. If all lines end in <CR><NL>, and 'fileformats' includes "dos", 'fileformat' is set to "dos".
  2. If a <NL> is found and 'fileformats' includes "unix", 'fileformat' is set to "unix". Note that when a <NL> is found without a preceding <CR>, "unix" is preferred over "dos".
  3. If 'fileformat' has not yet been set, and if a <CR> is found, and if 'fileformats' includes "mac", 'fileformat' is set to "mac". This means that "mac" is only chosen when:
     "unix" is not present or no <NL> is found in the file, and
     "dos" is not present or no <CR><NL> is found in the file.
     Except: if "unix" was chosen, but there is a <CR> before the first <NL>, and there appear to be more <CR>s than <NL>s in the first few lines, "mac" is used.
  4. If 'fileformat' is still not set, the first name from 'fileformats' is used.

  When reading a file into an existing buffer, the same is done, but this happens like 'fileformat' has been set appropriately for that file only, the option is not changed.
  When 'binary' is set, the value of 'fileformats' is not used.

When Vim starts up with an empty buffer the first item is used. You can overrule this by setting 'fileformat' in your .vimrc.

For systems with a Dos-like <EOL> (<CR><NL>), when reading files that are ":source"ed and for vimrc files, automatic <EOL> detection may be done:

- When 'fileformats' is empty, there is no automatic detection. Dos format will be used.
- When 'fileformats' is set to one or more names, automatic detection is done. This is based on the first <NL> in the file: If there is a

<CR> in front of it, Dos format is used, otherwise Unix format is
used.
Also see file-formats.

'fileignorecase' 'fic' 'nofileignorecase' 'nofic'
'fileignorecase' 'fic' boolean (default on for systems where case in file
names is normally ignored)
global
When set, case is ignored when using file and directory names.

This option is on by default on systems where the filesystem is
traditionally case-insensitive (for example MS-Windows and macOS).
However, Vim cannot determine at runtime whether a particular
filesystem is case-sensitive or case-insensitive.

See 'wildignorecase' for only ignoring case when doing completion.

'filetype' 'ft'
'filetype' 'ft' string (default "")
local to buffer local-noglobal
When this option is set, the FileType autocommand event is triggered.
All autocommands that match with the value of this option will be
executed. Thus the value of 'filetype' is used in place of the file
name.
Otherwise this option does not always reflect the current file type.
This option is normally set when the file type is detected. To enable
this use the ":filetype on" command. :filetype
Setting this option to a different value is most useful in a modeline,
for a file for which the file type is not automatically recognized.
Example, for in an IDL file:

```
/* vim: set filetype=idl : */
```

FileType filetypes
When a dot appears in the value then this separates two filetype
names, it should therefore not be used for a filetype. Example:

```
/* vim: set filetype=c.doxygen : */
```

This will use the "c" filetype first, then the "doxygen" filetype.
This works both for filetype plugins and for syntax files. More than
one dot may appear.
This option is not copied to another buffer, independent of the 's' or
'S' flag in 'cpoptions'.
Only alphanumeric characters, '-' and '_' can be used (and a '.' is
allowed as delimiter when combining different filetypes).

'fillchars' 'fcs'
'fillchars' 'fcs' string (default "")
global or local to window global-local
Characters to fill the statuslines, vertical separators, special
lines in the window and truncated text in the ins-completion-menu.
It is a comma-separated list of items. Each item has a name, a colon
and the value of that item: E1511

item	default	Used for
stl	' '	statusline of the current window
stlnc	' '	statusline of the non-current windows
wbr	' '	window bar
horiz	'─' or '-'	horizontal separators :split
horizup	'┴' or '-'	upwards facing horizontal separator
horizdown	'┬' or '-'	downwards facing horizontal separator
vert	'│' or '|'	vertical separators :vsplit
vertleft	'┤' or '|'	left facing vertical separator
vertright	'├' or '|'	right facing vertical separator
verthoriz	'┼' or '+'	overlapping vertical and horizontal separator
fold	'·' or '-'	filling 'foldtext'
foldopen	'-'	mark the beginning of a fold
foldclose	'+'	show a closed fold
foldsep	'│' or '|'	open fold middle marker
foldinner	none	character to show instead of the numeric foldlevel when it would be repeated in a narrow 'foldcolumn'
diff	'-'	deleted lines of the 'diff' option
msgsep	' '	message separator 'display'
eob	'~'	empty lines at the end of a buffer
lastline	'@'	'display' contains lastline/truncate
trunc	'>'	truncated text in the ins-completion-menu.
truncrl	'<'	same as "trunc" in 'rightleft' mode

Any one that is omitted will fall back to the default.

Note that "horiz", "horizup", "horizdown", "vertleft", "vertright" and
"verthoriz" are only used when 'laststatus' is 3, since only vertical
window separators are used otherwise.

If 'ambiwidth' is "double" then "horiz", "horizup", "horizdown",
"vert", "vertleft", "vertright", "verthoriz", "foldsep" and "fold"
default to single-byte alternatives.

Example:

```
set fillchars=stl:\ ,stlnc:\ ,vert:│,fold:·,diff:-
```

All items support single-byte and multibyte characters. But
double-width characters are not supported. E1512

The highlighting used for these items:

item	highlight group	
stl	StatusLine	hl-StatusLine
stlnc	StatusLineNC	hl-StatusLineNC
wbr	WinBar	hl-WinBar or hl-WinBarNC
horiz	WinSeparator	hl-WinSeparator
horizup	WinSeparator	hl-WinSeparator
horizdown	WinSeparator	hl-WinSeparator
vert	WinSeparator	hl-WinSeparator
vertleft	WinSeparator	hl-WinSeparator
vertright	WinSeparator	hl-WinSeparator
verthoriz	WinSeparator	hl-WinSeparator
fold	Folded	hl-Folded
foldopen	FoldColumn	hl-FoldColumn
foldclose	FoldColumn	hl-FoldColumn
foldsep	FoldColumn	hl-FoldColumn
diff	DiffDelete	hl-DiffDelete
msgsep	MsgSeparator	hl-MsgSeparator
eob	EndOfBuffer	hl-EndOfBuffer
lastline	NonText	hl-NonText
trunc	one of the many Popup menu highlighting groups like hl-PmenuSel	
truncrl	same as "trunc"	

'findfunc' 'ffu' E1514

'findfunc' 'ffu' string (default "")
global or local to buffer global-local
Disallowed in modeline. no-modeline-option

Function that is called to obtain the filename(s) for the :find
command. When this option is empty, the internal file-searching
mechanism is used.

The value can be the name of a function, a lambda or a Funcref.
See option-value-function for more information.

The function is called with two arguments. The first argument is a
String and is the :find command argument. The second argument is
a Boolean and is set to v:true when the function is called to get
a List of command-line completion matches for the :find command.
The function should return a List, which is handled similarly to the
return value of a :command-completion-customlist function.

The function can process all the directories specified in 'path'.

If a match is found, the function should return a List containing
one or more file names. If a match is not found, the function
should return an empty List.

If any errors are encountered during the function invocation, an
empty List is used as the return value.

It is not allowed to change text or jump to another window while
executing the 'findfunc' textlock.

Examples:

```
-- Use vim.fn.glob()
vim.o.findfunc = function(cmdarg, cmdcomplete)
  local pat = cmdcomplete and (cmdarg .. '*') or cmdarg
  return vim.fn.glob(pat, false, true)
end

-- Use the "git ls-files" output
vim.o.findfunc = function(cmdarg, cmdcomplete)
  local fnames = vim.fn.systemlist('git ls-files')
  return vim.tbl_filter(function(v)
    return v:lower():find(cmdarg:lower(), 1, true) ~= nil
  end, fnames)
end
```

'fixendofline' 'fixeol' 'nofixendofline' 'nofixeol'

'fixendofline' 'fixeol' boolean (default on)
local to buffer

When writing a file and this option is on, <EOL> at the end of file
will be restored if missing. Turn this option off if you want to
preserve the situation from the original file.
When the 'binary' option is set the value of this option doesn't
matter.
See the 'endofline' option.
See eol-and-eof for example settings.

'foldclose' 'fcl'

'foldclose' 'fcl' string (default "")
global

When set to "all", a fold is closed when the cursor isn't in it and

its level is higher than 'foldlevel'. Useful if you want folds to automatically close when moving out of them.

'foldcolumn' 'fdc'
'foldcolumn' 'fdc' string (default "0")
local to window
When and how to draw the foldcolumn. Valid values are:
"auto": resize to the minimum amount of folds to display.
"auto:[1-9]": resize to accommodate multiple folds up to the selected level
"0": to disable foldcolumn
"[1-9]": to display a fixed number of columns
See folding.

'foldenable' 'fen' 'nofoldenable' 'nofen'
'foldenable' 'fen' boolean (default on)
local to window
When off, all folds are open. This option can be used to quickly switch between showing all text unfolded and viewing the text with folds (including manually opened or closed folds). It can be toggled with the zi command. The 'foldcolumn' will remain blank when 'foldenable' is off.
This option is set by commands that create a new fold or close a fold.
See folding.

'foldexpr' 'fde'
'foldexpr' 'fde' string (default "0")
local to window
The expression used for when 'foldmethod' is "expr". It is evaluated for each line to obtain its fold level. The context is set to the script where 'foldexpr' was set, script-local items can be accessed.
See fold-expr for the usage.

The expression will be evaluated in the sandbox if set from a modeline, see sandbox-option.
This option can't be set from a modeline when the 'diff' option is on or the 'modelineexpr' option is off.

It is not allowed to change text or jump to another window while evaluating 'foldexpr' textlock.

'foldignore' 'fdi'
'foldignore' 'fdi' string (default "#")
local to window
Used only when 'foldmethod' is "indent". Lines starting with characters in 'foldignore' will get their fold level from surrounding lines. White space is skipped before checking for this character.
The default "#" works well for C programs. See fold-indent.

'foldlevel' 'fdl'
'foldlevel' 'fdl' number (default 0)
local to window
Sets the fold level: Folds with a higher level will be closed.
Setting this option to zero will close all folds. Higher numbers will close fewer folds.
This option is set by commands like zm, zM and zR.
See fold-foldlevel.

'foldlevelstart' 'fdls'
'foldlevelstart' 'fdls' number (default -1)
global
Sets 'foldlevel' when starting to edit another buffer in a window. Useful to always start editing with all folds closed (value zero), some folds closed (one) or no folds closed (99).
This is done before reading any modeline, thus a setting in a modeline overrules this option. Starting to edit a file for diff-mode also ignores this option and closes all folds.
It is also done before BufReadPre autocommands, to allow an autocmd to overrule the 'foldlevel' value for specific files.
When the value is negative, it is not used.

'foldmarker' 'fmr' E536
'foldmarker' 'fmr' string (default "{{{,}}}")
local to window
The start and end marker used when 'foldmethod' is "marker". There must be one comma, which separates the start and end marker. The marker is a literal string (a regular expression would be too slow).
See fold-marker.

'foldmethod' 'fdm'
'foldmethod' 'fdm' string (default "manual")
local to window
The kind of folding used for the current window. Possible values:

fold-manual	manual	Folds are created manually.
fold-indent	indent	Lines with equal indent form a fold.
fold-expr	expr	'foldexpr' gives the fold level of a line.
fold-marker	marker	Markers are used to specify folds.
fold-syntax	syntax	Syntax highlighting items specify folds.
fold-diff	diff	Fold text that is not changed.

'foldminlines' 'fml'
'foldminlines' 'fml' number (default 1)
local to window
Sets the number of screen lines above which a fold can be displayed closed. Also for manually closed folds. With the default value of one a fold can only be closed if it takes up two or more screen lines.

Set to zero to be able to close folds of just one screen line.
Note that this only has an effect on what is displayed. After using
"zc" to close a fold, which is displayed open because it's smaller
than 'foldminlines', a following "zc" may close a containing fold.

'foldnestmax' 'fdn'

'foldnestmax' 'fdn' number (default 20)
local to window
Sets the maximum nesting of folds for the "indent" and "syntax"
methods. This avoids that too many folds will be created. Using more
than 20 doesn't work, because the internal limit is 20.

'foldopen' 'fdo'

'foldopen' 'fdo' string (default "block,hor,mark,percent,quickfix,search,tag,undo")
global
Specifies for which type of commands folds will be opened, if the
command moves the cursor into a closed fold. It is a comma-separated
list of items.
NOTE: When the command is part of a mapping this option is not used.
Add the zv command to the mapping to get the same effect.
(rationale: the mapping may want to control opening folds itself)

item	commands
all	any
block	(, {, [[, [{, etc.
hor	horizontal movements: "l", "w", "fx", etc.
insert	any command in Insert mode
jump	far jumps: "G", "gg", etc.
mark	jumping to a mark: "'m", CTRL-O, etc.
percent	"%"
quickfix	":cn", ":crew", ":make", etc.
search	search for a pattern: "/", "n", "*", "gd", etc. (not for a search pattern in a ":" command) Also for [s and]s.
tag	jumping to a tag: ":ta", CTRL-T, etc.
undo	undo or redo: "u" and CTRL-R When a movement command is used for an operator (e.g., "dl" or "y%") this option is not used. This means the operator will include the whole closed fold. Note that vertical movements are not here, because it would make it very difficult to move onto a closed fold. In insert mode the folds containing the cursor will always be open when text is inserted. To close folds you can re-apply 'foldlevel' with the zx command or set the 'foldclose' option to "all".

'foldtext' 'fdt'

'foldtext' 'fdt' string (default "foldtext()")
local to window
An expression which is used to specify the text displayed for a closed
fold. The context is set to the script where 'foldexpr' was set,
script-local items can be accessed. See fold-foldtext for the
usage.

The expression will be evaluated in the sandbox if set from a
modeline, see sandbox-option.
This option cannot be set in a modeline when 'modelineexpr' is off.

It is not allowed to change text or jump to another window while
evaluating 'foldtext' textlock.

When set to an empty string, foldtext is disabled, and the line
is displayed normally with highlighting and no line wrapping.

'follow' 'nofollow'

'follow' boolean (default off)
local to buffer
Enables multicursor follow-mode: cursor-relative motions performed
by the primary cursor, cascade to all cursors. Toggled by g=
(buffer-local).

'formatexpr' 'fex'

'formatexpr' 'fex' string (default "")
local to buffer
Expression which is evaluated to format a range of lines for the gq
operator or automatic formatting (see 'formatoptions'). When this
option is empty 'formatprg' is used.

The v:lnum variable holds the first line to be formatted.
The v:count variable holds the number of lines to be formatted.
The v:char variable holds the character that is going to be
inserted if the expression is being evaluated due to
automatic formatting. This can be empty. Don't insert
it yet!

Example:

```
set formatexpr=mylang#Format()
```

This will invoke the mylang#Format() function in the
autoload/mylang.vim file in 'runtimepath'. autoload

The advantage of using a function call without arguments is that it is
faster, see expr-option-function.

The expression is also evaluated when 'textwidth' is set and adding
text beyond that limit. This happens under the same conditions as
when internal formatting is used. Make sure the cursor is kept in the

same spot relative to the text then! The mode() function will
return "i" or "R" in this situation.

When the expression evaluates to non-zero Vim will fall back to using
the internal format mechanism.

If the expression starts with s: or <SID>, then it is replaced with
the script ID (local-function). Example:

```
set formatexpr=s:MyFormatExpr()
set formatexpr=<SID>SomeFormatExpr()
```

Otherwise, the expression is evaluated in the context of the script
where the option was set, thus script-local items are available.

The expression will be evaluated in the sandbox when set from a
modeline, see sandbox-option. That stops the option from working,
since changing the buffer text is not allowed.
This option cannot be set in a modeline when 'modelineexpr' is off.

'formatlistpat' 'flp'
'formatlistpat' 'flp'   string (default "^\s*\d\+[\]:.)}\t]\s*")
local to buffer
A pattern that is used to recognize a list header. This is used for
the "n" flag in 'formatoptions'.
The pattern must match exactly the text that will be the indent for
the line below it. You can use /\ze to mark the end of the match
while still checking more characters. There must be a character
following the pattern, when it matches the whole line it is handled
like there is no match.
The default recognizes a number, followed by an optional punctuation
character and white space.

'formatoptions' 'fo'
'formatoptions' 'fo'   string (default "tcqj")
local to buffer
This is a sequence of letters which describes how automatic
formatting is to be done.
See fo-table for possible values and gq for how to format text.
Commas can be inserted for readability.
To avoid problems with flags that are added in the future, use the
"+=" and "-=" feature of ":set" add-option-flags.

'formatprg' 'fp'
'formatprg' 'fp'   string (default "")
global or local to buffer global-local
Disallowed in modeline. no-modeline-option
External program used to format lines with gq. Ignored if
'formatexpr' is set.

If empty, the internal C-indenting function will be used.

The program must take input on stdin and produce output on stdout. The
Unix program "fmt" is such a program. Environment variables are
expanded :set_env. See option-backslash about including spaces
and backslashes.

'fsync' 'fs' 'nofsync' 'nofs'
'fsync' 'fs'   boolean (default on)
global or local to buffer global-local
Disallowed in modeline. no-modeline-option
When on, the OS function fsync() will be called after saving a file
(:write, writefile(), …), swap-file, undo-persistence and shada-file.
This flushes the file to disk, ensuring that it is safely written.
Slow on some systems: writing buffers, quitting Nvim, and other
operations may sometimes take a few seconds.

Files are ALWAYS flushed ('fsync' is ignored) when:

- CursorHold event is triggered
- :preserve is called
- system signals low battery life
- Nvim exits abnormally

This is a global-local option, so it can be set per buffer, for
example when writing to a slow filesystem.

'grepformat' 'gfm'
'grepformat' 'gfm'   string (default "%f:%l:%m,%f:%l%m,%f %l%m")
global or local to buffer global-local
Format to recognize for the ":grep" command output.
This is a scanf-like string that uses the same format as the
'errorformat' option: see errorformat.

Defaults to "%f:%l:%c:%m" if ripgrep ('grepprg') is available.

'grepprg' 'gp'
'grepprg' 'gp'   string (default see below)
global or local to buffer global-local
Disallowed in modeline. no-modeline-option

Program to use for the :grep command.
Note: if you change this then you must also update 'grepformat'.

May contain "%" and "#" characters, are expanded per cmdline-special.
The placeholder "$*" specifies where the arguments will be included.
Environment variables are expanded :set_env. See option-backslash
about including spaces and backslashes.

Special value: When 'grepprg' is set to "internal" the :grep command
works like :vimgrep, :lgrep like :lvimgrep, :grepadd like
:vimgrepadd and :lgrepadd like :lvimgrepadd.

See also :make_makeprg, most of the comments there apply to 'grepprg'.

Defaults to:

- "rg --vimgrep -uu " if ripgrep is available (:checkhealth),
- "grep -HIn $* /dev/null" on Unix,
- "findstr /n $* nul" on Windows.

Ripgrep may perform additional filtering such as using .gitignore rules
and skipping hidden files. This is disabled by default (via "-u") to
more closely match the behaviour of standard grep.
You can make ripgrep match Vim's case handling using the
-i/--ignore-case and -S/--smart-case options. Handle OptionSet to
dynamically update 'grepprg' when e.g. 'ignorecase' is changed.

'guicursor' 'gcr' E545 E546 E548 E549

'guicursor' 'gcr' string (default "n-v-c-sm:block,i-ci-ve:ver25,r-cr-o:hor20,t:block-blinkon500-blinkoff500-TermCursor")
global

Configures the cursor style for each mode. Works in the GUI and many
terminals. See tui-cursor-shape.

To disable cursor-styling, reset the option:

```
set guicursor=
```

To enable mode shapes, "Cursor" highlight, and blinking:

```
set guicursor=n-v-c:block,i-ci-ve:ver25,r-cr:hor20,o:hor50
  \,a:blinkwait700-blinkoff400-blinkon250-Cursor/lCursor
  \,sm:block-blinkwait175-blinkoff150-blinkon175
```

The option is a comma-separated list of parts. Each part consists of a
mode-list and an argument-list:
        mode-list:argument-list,mode-list:argument-list,..
The mode-list is a dash separated list of these modes:
        n   Normal mode
        v   Visual mode
        ve   Visual mode with 'selection' "exclusive" (same as 'v',
                if not specified)
        o   Operator-pending mode
        i   Insert mode
        r   Replace mode
        c   Command-line Normal (append) mode
        ci   Command-line Insert mode
        cr   Command-line Replace mode
        sm   showmatch in Insert mode
        t   Terminal mode
        a   all modes
The argument-list is a dash separated list of these arguments:
        hor{N} horizontal bar, {N} percent of the character height
        ver{N} vertical bar, {N} percent of the character width
        block   block cursor, fills the whole character

- Only one of the above three should be present.
- Default is "block" for each mode.

blinkwait{N} cursor-blinking

blinkon{N}
blinkoff{N}
        blink times for cursor: blinkwait is the delay before
        the cursor starts blinking, blinkon is the time that
        the cursor is shown and blinkoff is the time that the
        cursor is not shown. Times are in msec. When one of
        the numbers is zero, there is no blinking. E.g.:

```
set guicursor=n:blinkon0
```

        Default is "blinkon0" for each mode.
{group-name}
        Highlight group that decides the color and font of the
        cursor.
        In the TUI:

- inverse/reverse and no group-name are interpreted

                        as "host-terminal default cursor colors" which
                        typically means "inverted bg and fg colors".
- ctermfg and guifg are ignored.

                {group-name}/{group-name}
                        Two highlight group names, the first is used when
                        no language mappings are used, the other when they
                        are. language-mapping

        Examples of parts:
           n-c-v:block-nCursor In Normal, Command-line and Visual mode, use a
                                block cursor with colors from the "nCursor"
                                highlight group
           n-v-c-sm:block,i-ci-ve:ver25-Cursor,r-cr-o:hor20
                                In Normal et al. modes, use a block cursor
                                with the default colors defined by the host
                                terminal. In Insert-like modes, use
                                a vertical bar cursor with colors from
                                "Cursor" highlight group. In Replace-like
                                modes, use an underline cursor with
                                default colors.
           i-ci:ver30-iCursor-blinkwait300-blinkon200-blinkoff150
                                In Insert and Command-line Insert mode, use a
                                30% vertical bar cursor with colors from the
                                "iCursor" highlight group. Blink a bit
                                faster.

        The 'a' mode is different. It will set the given argument-list for
        all modes. It does not reset anything to defaults. This can be used
        to do a common setting for all modes. For example, to switch off
        blinking: "a:blinkon0"

        Examples of cursor highlighting:

```
highlight Cursor gui=reverse guifg=NONE guibg=NONE
" Note: gui=reverse overrides colors.
highlight Cursor gui=NONE guifg=bg guibg=fg
```

                                        'guifont' 'gfn' E235 E596
'guifont' 'gfn'   string (default "DejaVu Sans Mono,Courier New,monospace"
                                 Mac: "SF Mono,Menlo,Monaco,Courier New,monospace"
                                 Linux: "Source Code Pro,DejaVu Sans Mono,Courier New,monospace"
                                 MS-Windows: "Cascadia Code,Cascadia Mono,Consolas,Courier New,monospace")
                        global
        This is a list of fonts which will be used for the GUI version of Vim.
        In its simplest form the value is just one font name. When
        the font cannot be found you will get an error message. To try other
        font names a list can be specified, font names separated with commas.
        The first valid font is used.

        Spaces after a comma are ignored. To include a comma in a font name
        precede it with a backslash. Setting an option requires an extra
        backslash before a space and a backslash. See also
        option-backslash. For example:

```
set guifont=Screen15,\ 7x13,font\\,with\\,commas
```

        will make Vim try to use the font "Screen15" first, and if it fails it
        will try to use "7x13" and then "font,with,commas" instead.

        If none of the fonts can be loaded, Vim will keep the current setting.
        If an empty font list is given, Vim will try using other resource
        settings (for X, it will use the Vim.font resource), and finally it
        will try some builtin default which should always be there ("7x13" in
        the case of X). The font names given should be "normal" fonts. Vim
        will try to find the related bold and italic fonts.

        For Win32 and Mac OS:

```
set guifont=*
```

        will bring up a font requester, where you can pick the font you want.

        The font name depends on the GUI used.

        For Mac OSX you can use something like this:

```
set guifont=Monaco:h10
```

                                                                E236

        Note that the fonts must be mono-spaced (all characters have the same
        width).

        To preview a font on X11, you might be able to use the "xfontsel"
        program. The "xlsfonts" program gives a list of all available fonts.

        For the Win32 GUI   E244 E245
- takes these options in the font name:

hXX - height is XX (points, can be floating-point)
wXX - width is XX (points, can be floating-point)
b - bold
i - italic
u - underline
s - strikeout
cXX - character set XX. Valid charsets are: ANSI, ARABIC,
BALTIC, CHINESEBIG5, DEFAULT, EASTEUROPE, GB2312, GREEK,
HANGEUL, HEBREW, JOHAB, MAC, OEM, RUSSIAN, SHIFTJIS,
SYMBOL, THAI, TURKISH, VIETNAMESE ANSI and BALTIC.
Normally you would use "cDEFAULT".

Use a ':' to separate the options.

- A '_' can be used in the place of a space, so you don't need to use

backslashes to escape the spaces.

- Examples:

```
set guifont=courier_new:h12:w5:b:cRUSSIAN
set guifont=Andale_Mono:h7.5:w4.5
```

'guifontwide' 'gfw' E231 E533 E534
'guifontwide' 'gfw' string (default "")
global
Comma-separated list of fonts to be used for double-width characters.
The first font that can be loaded is used.
Note: The size of these fonts must be exactly twice as wide as the one
specified with 'guifont' and the same height.

When 'guifont' has a valid font and 'guifontwide' is empty Vim will
attempt to set 'guifontwide' to a matching double-width font.

'helpfile' 'hf'
'helpfile' 'hf' string (default "$VIMRUNTIME/doc/help.txt")
global
Disallowed in modeline. no-modeline-option
Name of the main help file. All distributed help files should be
placed together in one directory. Additionally, all "doc" directories
in 'runtimepath' will be used.
Environment variables are expanded :set_env. For example:
"$VIMRUNTIME/doc/help.txt". If $VIMRUNTIME is not set, $VIM is also
tried. Also see $VIMRUNTIME and option-backslash about including
spaces and backslashes.

'helpheight' 'hh'
'helpheight' 'hh' number (default 20)
global
Minimal initial height of the help window when it is opened with the
":help" command. The initial height of the help window is half of the
current window, or (when the 'ea' option is on) the same as other
windows. When the height is less than 'helpheight', the height is
set to 'helpheight'. Set to zero to disable.

'helplang' 'hlg'
'helplang' 'hlg' string (default messages language or empty)
global
Comma-separated list of languages. Vim will use the first language
for which the desired help can be found. The English help will always
be used as a last resort. You can add "en" to prefer English over
another language, but that will only find tags that exist in that
language and not in the English help.
Example:

```
set helplang=de,it
```

This will first search German, then Italian and finally English help
files.
When using CTRL-] and ":help!" in a non-English help file Vim will
try to find the tag in the current language before using this option.
See help-translated.

'hidden' 'hid' 'nohidden' 'nohid'
'hidden' 'hid' boolean (default on)
global
When off a buffer is unloaded (including loss of undo information)
when it is abandoned. When on a buffer becomes hidden when it is
abandoned. A buffer displayed in another window does not become
hidden, of course.

Commands that move through the buffer list sometimes hide a buffer
although the 'hidden' option is off when these three are true:

- the buffer is modified

- 'autowrite' is off or writing is not possible

- the '!' flag was used

Also see windows.

To hide a specific buffer use the 'bufhidden' option.
'hidden' is set for one command with ":hide {command}" :hide.

'history' 'hi'

'history' 'hi'		number (default 10000)
			global
A history of ":" commands, and a history of previous search patterns
is remembered. This option decides how many entries may be stored in
each of these histories (see cmdline-editing and 'messagesopt' for
the number of messages to remember).
The maximum value is 10000.

'hlsearch' 'hls' 'nohlsearch' 'nohls'

'hlsearch' 'hls'		boolean (default on)
			global
When there is a previous search pattern, highlight all its matches.
The hl-Search highlight group determines the highlighting for all
matches not under the cursor while the hl-CurSearch highlight group
(if defined) determines the highlighting for the match under the
cursor. If hl-CurSearch is not defined, then hl-Search is used for
both. Note that only the matching text is highlighted, any offsets
are not applied.
See also: 'incsearch' and :match.
When you get bored looking at the highlighted matches, you can turn it
off with :nohlsearch. This does not change the option value, as
soon as you use a search command, the highlighting comes back.
'redrawtime' specifies the maximum time spent on finding matches.
When the search pattern can match an end-of-line, Vim will try to
highlight all of the matched text. However, this depends on where the
search starts. This will be the first line in the window or the first
line below a closed fold. A match in a previous line which is not
drawn may not continue in a newly drawn line.
You can specify whether the highlight status is restored on startup
with the 'h' flag in 'shada' shada-h.

'icon' 'noicon'

'icon'			boolean (default off, on when title can be restored)
			global
When on, the icon text of the window will be set to the value of
'iconstring' (if it is not empty), or to the name of the file
currently being edited. Only the last part of the name is used.
Overridden by the 'iconstring' option.
Only works if the terminal supports setting window icons.

'iconstring'

'iconstring'		string (default "")
			global
When this option is not empty, it will be used for the icon text of
the window. This happens only when the 'icon' option is on.
Only works if the terminal supports setting window icon text
When this option contains printf-style '%' items, they will be
expanded according to the rules used for 'statusline'. See
'titlestring' for example settings.
This option cannot be set in a modeline when 'modelineexpr' is off.

'ignorecase' 'ic' 'noignorecase' 'noic'

'ignorecase' 'ic'	boolean (default off)
			global
Ignore case in search patterns, cmdline-completion, when
searching in the tags file, expr-== and for Insert-mode completion
ins-completion.
Also see 'smartcase' and 'tagcase'.
Can be overruled by using "\c" or "\C" in the pattern, see
/ignorecase.

'iminsert' 'imi'

'iminsert' 'imi'	number (default 0)
			local to buffer
Specifies whether :lmap or an Input Method (IM) is to be used in
Insert mode. Valid values:
		0	:lmap is off and IM is off
		1	:lmap is ON and IM is off
		2	:lmap is off and IM is ON
To always reset the option to zero when leaving Insert mode with <Esc>
this can be used:

```
inoremap <ESC> <ESC>:set iminsert=0<CR>
```

This makes :lmap and IM turn off automatically when leaving Insert
mode.
Note that this option changes when using CTRL-^ in Insert mode
i_CTRL-^.
The value is set to 1 when setting 'keymap' to a valid keymap name.
It is also used for the argument of commands like "r" and "f".

'imsearch' 'ims'

'imsearch' 'ims'	number (default -1)
			local to buffer
Specifies whether :lmap or an Input Method (IM) is to be used when
entering a search pattern. Valid values:
		-1	the value of 'iminsert' is used, makes it look like
			'iminsert' is also used when typing a search pattern
		0	:lmap is off and IM is off

1 :lmap is ON and IM is off
2 :lmap is off and IM is ON
Note that this option changes when using CTRL-^ in Command-line mode
c_CTRL-^.
The value is set to 1 when it is not -1 and setting the 'keymap'
option to a valid keymap name.

'inccommand' 'icm'
'inccommand' 'icm' string (default "nosplit")
global
When nonempty, shows the effects of :substitute, :smagic,
:snomagic and user commands with the :command-preview flag as you
type.

Possible values:
nosplit Shows the effects of a command incrementally in the
buffer.
split Like "nosplit", but also shows partial off-screen
results in a preview window.

If the preview for built-in commands is too slow (exceeds
'redrawtime') then 'inccommand' is automatically disabled until
Command-line-mode is done.

'include' 'inc'
'include' 'inc' string (default "")
global or local to buffer global-local
Pattern to be used to find an include command. It is a search
pattern, just like for the "/" command (See pattern). This option
is used for the commands "[i", "]I", "[d", etc.
Normally the 'isfname' option is used to recognize the file name that
comes after the matched pattern. But if "\zs" appears in the pattern
then the text matched from "\zs" to the end, or until "\ze" if it
appears, is used as the file name. Use this to include characters
that are not in 'isfname', such as a space. You can then use
'includeexpr' to process the matched text.
See option-backslash about including spaces and backslashes.

'includeexpr' 'inex'
'includeexpr' 'inex' string (default "")
local to buffer
Expression to be used to transform the string found with the 'include'
option to a file name. Mostly useful to change "." to "/" for Java:

```
setlocal includeexpr=substitute(v:fname,'\\.','/','g')
```

The "v:fname" variable will be set to the file name that was detected.
Note the double backslash: the :set command first halves them, then
one remains in the value, where "\." matches a dot literally. For
simple character replacements tr() avoids the need for escaping:

```
setlocal includeexpr=tr(v:fname,'.','/')
```

Also used for the gf command if an unmodified file name can't be
found. Allows doing "gf" on the name after an 'include' statement.
Note: Not used for <cfile>.

If the expression starts with s: or <SID>, then it is replaced with
the script ID (local-function). Example:

```
setlocal includeexpr=s:MyIncludeExpr()
setlocal includeexpr=<SID>SomeIncludeExpr()
```

Otherwise, the expression is evaluated in the context of the script
where the option was set, thus script-local items are available.

It is more efficient if the value is just a function call without
arguments, see expr-option-function.

The expression will be evaluated in the sandbox when set from a
modeline, see sandbox-option.
This option cannot be set in a modeline when 'modelineexpr' is off.

It is not allowed to change text or jump to another window while
evaluating 'includeexpr' textlock.

'incsearch' 'is' 'noincsearch' 'nois'
'incsearch' 'is' boolean (default on)
global
While typing a search command, show where the pattern, as it was typed
so far, matches. The matched string is highlighted. If the pattern
is invalid or not found, nothing is shown. The screen will be updated
often, this is only useful on fast terminals.
Note that the match will be shown, but the cursor will return to its
original position when no match is found and when pressing <Esc>. You
still need to finish the search command with <Enter> to move the
cursor to the match.
You can use the CTRL-G and CTRL-T keys to move to the next and
previous match. c_CTRL-G c_CTRL-T
Vim only searches for about half a second. With a complicated
pattern and/or a lot of text the match may not be found. This is to
avoid that Vim hangs while you are typing the pattern.
The hl-IncSearch highlight group determines the highlighting.
When 'hlsearch' is on, all matched strings are highlighted too while
typing a search command. See also: 'hlsearch'.

If you don't want to turn 'hlsearch' on, but want to highlight all matches while searching, you can turn on and off 'hlsearch' with autocmd. Example:

```
augroup vimrc-incsearch-highlight
  autocmd!
  autocmd CmdlineEnter [\/\?] :set hlsearch
  autocmd CmdlineLeave [\/\?] :set nohlsearch
augroup END
```

CTRL-L can be used to add one character from after the current match to the command line. If 'ignorecase' and 'smartcase' are set and the command line has no uppercase characters, the added character is converted to lowercase.
CTRL-R CTRL-W can be used to add the word at the end of the current match, excluding the characters that were already typed (starting from the beginning of the word).

'indentexpr' 'inde'
'indentexpr' 'inde' string (default "")
local to buffer

Expression which is evaluated to obtain the proper indent for a line. It is used when a new line is created, for the = operator and in Insert mode as specified with the 'indentkeys' option. When this option is not empty, it overrules the 'cindent' and 'smartindent' indenting. When 'lisp' is set, this option is only used when 'lispoptions' contains "expr:1". The expression is evaluated with v:lnum set to the line number for which the indent is to be computed. The cursor is also in this line when the expression is evaluated (but it may be moved around).

If the expression starts with s: or <SID>, then it is replaced with the script ID (local-function). Example:

```
set indentexpr=s:MyIndentExpr()
set indentexpr=<SID>SomeIndentExpr()
```

Otherwise, the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

The advantage of using a function call without arguments is that it is faster, see expr-option-function.

The expression must return the number of spaces worth of indent. It can return "-1" to keep the current indent (this means 'autoindent' is used for the indent).
Functions useful for computing the indent are indent(), cindent() and lispindent().
The evaluation of the expression must not have side effects! It must not change the text, jump to another window, etc. Afterwards the cursor position is always restored, thus the cursor may be moved.
Normally this option would be set to call a function:

```
set indentexpr=GetMyIndent()
```

Error messages will be suppressed, unless the 'debug' option contains "msg".
See indent-expression.

The expression will be evaluated in the sandbox when set from a modeline, see sandbox-option.
This option cannot be set in a modeline when 'modelineexpr' is off.

It is not allowed to change text or jump to another window while evaluating 'indentexpr' textlock.

'indentkeys' 'indk'
'indentkeys' 'indk' string (default "0{,0},0),0],:,0#,!^F,o,O,e")
local to buffer

A list of keys that, when typed in Insert mode, cause reindenting of the current line. Only happens if 'indentexpr' isn't empty.
The format is identical to 'cinkeys', see indentkeys-format.
See C-indenting and indent-expression.

'infercase' 'inf' 'noinfercase' 'noinf'
'infercase' 'inf' boolean (default off)
local to buffer

When doing keyword completion in insert mode ins-completion, and 'ignorecase' is also on, the case of the match is adjusted depending on the typed text. If the typed text contains a lowercase letter where the match has an upper case letter, the completed part is made lowercase. If the typed text has no lowercase letters and the match has a lowercase letter where the typed text has an uppercase letter, and there is a letter before it, the completed part is made uppercase. With 'noinfercase' the match is used as-is.

'isfname' 'isf'
'isfname' 'isf' string (default for Windows:
"@,48-57,/,\,.,-,_,+,,,#,$,%,{,},[,],@-@,!,~,="
otherwise: "@,48-57,/,.,-,_,+,,,#,$,%,~,=")
global

The characters specified by this option are included in file names and path names. Filenames are used for commands like "gf", "[i" and in the tags file. It is also used for "\f" in a pattern.
Multi-byte characters 256 and above are always included, only the

characters up to 255 are specified with this option.
For UTF-8 the characters 0xa0 to 0xff are included as well.
Think twice before adding white space to this option. Although a
space may appear inside a file name, the effect will be that Vim
doesn't know where a file name starts or ends when doing completion.
It most likely works better without a space in 'isfname'.

Note that on systems using a backslash as path separator, Vim tries to
do its best to make it work as you would expect. That is a bit
tricky, since Vi originally used the backslash to escape special
characters. Vim will not remove a backslash in front of a normal file
name character on these systems, but it will on Unix and alikes. The
'&' and '^' are not included by default, because these are special for
cmd.exe.

The format of this option is a list of parts, separated with commas.
Each part can be a single character number or a range. A range is two
character numbers with '-' in between. A character number can be a
decimal number between 0 and 255 or the ASCII character itself (does
not work for digits). Example:

```
        "_,-,128-140,#-43"      (include '_' and '-' and the range
                                128 to 140 and '#' to 43)
```

If a part starts with '^', the following character number or range
will be excluded from the option. The option is interpreted from left
to right. Put the excluded character after the range where it is
included. To include '^' itself use it as the last character of the
option or the end of a range. Example:

```
        "^a-z,#,^"      (exclude 'a' to 'z', include '#' and '^')
```

If the character is '@', all characters where isalpha() returns TRUE
are included. Normally these are the characters a to z and A to Z,
plus accented characters. To include '@' itself use "@-@". Examples:

```
        "@,^a-z"        All alphabetic characters, excluding lower
                        case ASCII letters.
        "a-z,A-Z,@-@"   All letters plus the '@' character.
```

A comma can be included by using it where a character number is
expected. Example:

```
        "48-57,,,_"     Digits, comma and underscore.
```

A comma can be excluded by prepending a '^'. Example:

```
        " -~,^,,9"      All characters from space to '~', excluding
                        comma, plus <Tab>.
```

See option-backslash about including spaces and backslashes.

'isident' 'isi'

'isident' 'isi' string (default "@,48-57,_,192-255")
global

The characters given by this option are included in identifiers.
Identifiers are used after a match of the 'define' option. It is also
used for "\i" in a pattern. See 'isfname' for a description of the
format of this option. For '@' only characters up to 255 are used.

Does not affect environment variable names expr-env.

'iskeyword' 'isk'

'iskeyword' 'isk' string (default "@,48-57,_,192-255")
local to buffer

Keywords are used in searching and recognizing with many commands:
"w", "*", "[i", etc. It is also used for "\k" in a pattern. See
'isfname' for a description of the format of this option. For '@'
characters above 255 check the "word" character class (any character
that is categorized as a letter, number or emoji according to the
Unicode general category).

Note that there is a difference between the "\k" character class and
the word motion. The former matches any word character, while the
latter stops at a change of the character class.

For C programs you could use "a-z,A-Z,48-57,_,.,-,>".
For a help file it is set to all non-blank printable characters except
"*", '"' and '|' (so that CTRL-] on a command finds the help for that
command).
When the 'lisp' option is on the '-' character is always included.
This option also influences syntax highlighting, unless the syntax
uses :syn-iskeyword.

'joinspaces' 'js' 'nojoinspaces' 'nojs'

'joinspaces' 'js' boolean (default off)
global

Insert two spaces after a '.', '?' and '!' with a join command.
Otherwise only one space is inserted.

'jumpoptions' 'jop'

'jumpoptions' 'jop' string (default "clean")
global

List of words that change the behavior of the jumplist.

```
  stack         Make the jumplist behave like the tagstack.
                Relative location of entries in the jumplist is
                preserved at the cost of discarding subsequent entries
                when navigating backwards in the jumplist and then
                jumping to a location.  jumplist-stack

  view          When moving through the jumplist, changelist,
                alternate-file, using mark-motions or when popping
                the tagstack try to restore the mark-view in which
                the action occurred.

  clean         Remove unloaded buffers from the jumplist.
```

'keymap' 'kmp' E544

'keymap' 'kmp' string (default "")
local to buffer

Name of a keyboard mapping. See mbyte-keymap.
Setting this option to a valid keymap name has the side effect of setting 'iminsert' to one, so that the keymap becomes effective.
'imsearch' is also set to one, unless it was -1
Only alphanumeric characters, '.', '-' and '_' can be used.

'keymodel' 'km'

'keymodel' 'km' string (default "")
global

List of comma-separated words, which enable special things that keys can do. These values can be used:

- startsel Using a shifted special key starts selection (either Select mode or Visual mode, depending on "key" being present in 'selectmode').
- stopsel Using a not-shifted special key stops selection.

Special keys in this context are the cursor keys, <End>, <Home>, <PageUp> and <PageDown>.

'keywordprg' 'kp'

'keywordprg' 'kp' string (default ":Man", Windows: ":help")
global or local to buffer global-local
Disallowed in modeline. no-modeline-option

Program to use for the K command. Environment variables are expanded :set_env.

Special cases:

- ":help" opens the word at cursor using :help. (Note that previously setting the global option to the empty value did this, which is now deprecated.)
- ":help!" performs :help! (DWIM) on the WORD at cursor.
- If the value starts with ":", it is invoked as an Ex command and [count] is passed as the first argument, if present.
- If "man" or "man -s", [count] is the manpage section number.

See option-backslash about including spaces and backslashes.

Example:

```
set keywordprg=:help!
set keywordprg=man\ -s
set keywordprg=:Man
```

'langmap' 'lmap' E357 E358

'langmap' 'lmap' string (default "")
global
Disallowed in modeline. no-modeline-option

This option allows switching your keyboard into a special language mode. When you are typing text in Insert mode the characters are inserted directly. When in Normal mode the 'langmap' option takes care of translating these special characters to the original meaning of the key. This means you don't have to change the keyboard mode to be able to execute Normal mode commands.
This is the opposite of the 'keymap' option, where characters are mapped in Insert mode.
Also consider setting 'langremap' to off, to prevent 'langmap' from applying to characters resulting from a mapping.

Example (for Greek, in UTF-8): greek

```
set
langmap=AA,BB,ΨC,ΔD,EE,ΦF,ΓG,HH,II,ΞJ,KK,ΛL,MM,NN,OO,ΠP,QQ,PR,ΣS,TT,ΘU,ΩV,WW,XX,YY,ZZ,αa,βb,ψc,δd,εe,φf,γg,ηh,ιi,ξj,κk,λl,μm,νn,οο,πp,qq,ρr
```

Example (exchanges meaning of z and y for commands):

```
set langmap=zy,yz,ZY,YZ
```

The 'langmap' option is a list of parts, separated with commas. Each part can be in one of two forms:

1. A list of pairs. Each pair is a "from" character immediately followed by the "to" character. Examples: "aA", "aAbBcC".
2. A list of "from" characters, a semicolon and a list of "to" characters. Example: "abc;ABC"
   Example: "aA,fgh;FGH,cCdDeE"
   Special characters need to be preceded with a backslash. These are ";", ',', '"', '|' and backslash itself.

This will allow you to activate vim actions without having to switch back and forth between the languages. Your language characters will be understood as normal vim English characters (according to the

langmap mappings) in the following cases:
 o Normal/Visual mode (commands, buffer/register names, user mappings)
 o Insert/Replace Mode: Register names after CTRL-R
 o Insert/Replace Mode: Mappings
Characters entered in Command-line mode will NOT be affected by
this option. Note that this option can be changed at any time
allowing to switch between mappings for different languages/encodings.
Use a mapping to avoid having to type it each time!

'langmenu' 'lm'
'langmenu' 'lm' string (default "")
global
Language to use for menu translation. Tells which file is loaded
from the "lang" directory in 'runtimepath':

```
"lang/menu_" .. &langmenu .. ".vim"
```

(without the spaces). For example, to always use the Dutch menus, no
matter what $LANG is set to:

```
set langmenu=nl_NL.ISO_8859-1
```

When 'langmenu' is empty, v:lang is used.
Only normal file name characters can be used, /*?[|<> are illegal.
If your $LANG is set to a non-English language but you do want to use
the English menus:

```
set langmenu=none
```

This option must be set before loading menus, switching on filetype
detection or syntax highlighting. Once the menus are defined setting
this option has no effect. But you could do this:

```
source $VIMRUNTIME/delmenu.vim
set langmenu=de_DE.ISO_8859-1
source $VIMRUNTIME/menu.vim
```

Warning: This deletes all menus that you defined yourself!

'langremap' 'lrm' 'nolangremap' 'nolrm'
'langremap' 'lrm' boolean (default off)
global
When off, setting 'langmap' does not apply to characters resulting
from a mapping. If setting 'langmap' disables some of your mappings,
make sure this option is off.

'laststatus' 'ls'
'laststatus' 'ls' number (default 2)
global
The value of this option influences when the last window will have a
status line:
0: never
1: only if there are at least two windows
2: always
3: always and ONLY the last window

Here "last window" means the last window in a column, i.e. the bottom-
most one, just above the command line.

The screen looks nicer with a status line if you have several
windows, but it takes another screen line. status-line

'lazyredraw' 'lz' 'nolazyredraw' 'nolz'
'lazyredraw' 'lz' boolean (default off)
global
When this option is set, the screen will not be redrawn while
executing macros, registers and other commands that have not been
typed. Also, updating the window title is postponed. To force an
update use :redraw.
This may occasionally cause display errors. It is only meant to be
set temporarily when performing an operation where redrawing may cause
flickering or cause a slowdown.

'lhistory' 'lhi'
'lhistory' 'lhi' number (default 10)
local to window
Like 'chistory', but for the location list stack associated with a
window. If the option is changed in either the location list window
itself or the window that is associated with the location list stack,
the new value will also be applied to the other one. This means this
value will always be the same for a given location list window and its
corresponding window. See quickfix-stack for additional info.

'linebreak' 'lbr' 'nolinebreak' 'nolbr'
'linebreak' 'lbr' boolean (default off)
local to window
If on, Vim will wrap long lines at a character in 'breakat' rather
than at the last character that fits on the screen. Unlike
'wrapmargin' and 'textwidth', this does not insert <EOL>s in the file,
it only affects the way the file is displayed, not its contents.
If 'breakindent' is set, line is visually indented. Then, the value
of 'showbreak' is used to put in front of wrapped lines. This option
is not used when the 'wrap' option is off.

Note that <Tab> characters after an <EOL> are mostly not displayed
with the right amount of white space.

'lines' E593

'lines' number (default 24 or terminal height)
global
Number of lines of the Vim window.
Normally you don't need to set this. It is done automatically by the
terminal initialization code.
When Vim is running in the GUI or in a resizable window, setting this
option will cause the window size to be changed. When you only want
to use the size for the GUI, put the command in your gvimrc file.
Vim limits the number of lines to what fits on the screen. You can
use this command to get the tallest window possible:

```
set lines=999
```

Minimum value is 2, maximum value is 1000.

'linespace' 'lsp'

'linespace' 'lsp' number (default 0)
global
only in the GUI
Number of pixel lines inserted between characters. Useful if the font
uses the full character cell height, making lines touch each other.
When non-zero there is room for underlining.
With some fonts there can be too much room between lines (to have
space for ascents and descents). Then it makes sense to set
'linespace' to a negative value. This may cause display problems
though!

'lisp' 'nolisp'

'lisp' boolean (default off)
local to buffer
Lisp mode: When <Enter> is typed in insert mode set the indent for
the next line to Lisp standards (well, sort of). Also happens with
"cc" or "S". 'autoindent' must also be on for this to work.
Also see 'lispwords'.
The '-' character is included in keyword characters. Redefines the
"=" operator to use this same indentation algorithm rather than
calling an external program if 'equalprg' is empty.

'lispoptions' 'lop'

'lispoptions' 'lop' string (default "")
local to buffer
Comma-separated list of items that influence the Lisp indenting when
enabled with the 'lisp' option. Currently only one item is supported:
expr:1 use 'indentexpr' for Lisp indenting when it is set
expr:0 do not use 'indentexpr' for Lisp indenting (default)
Note that when using 'indentexpr' the = operator indents all the
lines, otherwise the first line is not indented (Vi-compatible).

'lispwords' 'lw'

'lispwords' 'lw' string (default is very long)
global or local to buffer global-local
Comma-separated list of words that influence the Lisp indenting when
enabled with the 'lisp' option.

'list' 'nolist'

'list' boolean (default off)
local to window
List mode: By default, show tabs as ">", trailing spaces as "-", and
non-breakable space characters as "+". Useful to see the difference
between tabs and spaces and for trailing blanks. Further changed by
the 'listchars' option.

When 'listchars' does not contain "tab" field, tabs are shown as "^I"
or "<09>", like how unprintable characters are displayed.

The cursor is displayed at the start of the space a Tab character
occupies, not at the end as usual in Normal mode. To get this cursor
position while displaying Tabs with spaces, use:

```
let &list = v:true | let &lcs = 'tab:  '
```

Note that list mode will also affect formatting (set with 'textwidth'
or 'wrapmargin') when 'cpoptions' includes 'L'. See 'listchars' for
changing the way tabs are displayed.

'listchars' 'lcs'

'listchars' 'lcs' string (default "tab:> ,trail:-,nbsp:+")
global or local to window global-local
Strings to use in 'list' mode and for the :list command. It is a
comma-separated list of string settings. E1511

lcs-eol

eol:c Character to show at the end of each line. When
omitted, there is no extra character at the end of the
line.

lcs-tab

tab:xy[z] Two or three characters to be used to show a tab.
The third character is optional.

tab:xy The 'x' is always used, then 'y' as many times as will fit. Thus "tab:>-" displays:

```
>
>-
>--
etc.
```

tab:xyz The 'z' is always used, then 'x' is prepended, and then 'y' is used as many times as will fit. Thus "tab:<->" displays:

```
>
<>
<->
<-->
etc.
```

When "tab:" is omitted, a tab is shown as ^I.

lcs-space

space:c Character to show for a space. When omitted, spaces are left blank.

lcs-multispace

multispace:c...
One or more characters to use cyclically to show for multiple consecutive spaces. Overrides the "space" setting, except for single spaces. When omitted, the "space" setting is used. For example, :set listchars=multispace:---+ shows ten consecutive spaces as:

```
---+---+--
```

lcs-lead

lead:c Character to show for leading spaces. When omitted, leading spaces are blank. Overrides the "space" and "multispace" settings for leading spaces. You can combine it with "tab:", for example:

```
set listchars+=tab:>-,lead:.
```

lcs-leadmultispace indent-guides

leadmultispace:c...
Like the lcs-multispace value, but for leading spaces only. Also overrides lcs-lead for leading multiple spaces.
:set listchars=leadmultispace:---+ shows ten consecutive leading spaces as:

```
---+---+--XXX
```

Where "XXX" denotes the first non-blank characters in the line.

Combined with lcs-leadtab, this can be used to show "indentation guides" (vertical lines).
For example, with 'shiftwidth' 2:

```
set list listchars=leadtab:\ \ |,tab:\ \ |,leadmultispace:\ \ |
```

For richer rendering (per-level colors, treesitter-aware scopes, etc.) use a third-party plugin.

lcs-leadtab

leadtab:xy[z]
Like lcs-tab, but only for leading tabs. When omitted, the "tab" setting is used for leading tabs. lcs-tab must also be set for this to work. E1572
You can combine it with "tab:", for example:

```
let &listchars = 'tab:>-,leadtab:. '
```

This shows leading tabs as periods(.) and other tabs as ">--".

lcs-trail

trail:c Character to show for trailing spaces. When omitted, trailing spaces are blank. Overrides the "space" and "multispace" settings for trailing spaces.

lcs-extends

extends:c Character to show in the last column, when 'wrap' is off and the line continues beyond the right of the screen.

lcs-precedes

precedes:c Character to show in the first visible column of the

physical line, when there is text preceding the
character visible in the first column.

lcs-conceal

conceal:c Character to show in place of concealed text, when
'conceallevel' is set to 1. A space when omitted.

lcs-nbsp

nbsp:c Character to show for a non-breakable space character
(0xA0 (160 decimal) and U+202F). Left blank when
omitted.

The characters ':' and ',' should not be used. UTF-8 characters can
be used. All characters must be single width. E1512

Each character can be specified as hex:

```
set listchars=eol:\\x24
set listchars=eol:\\u21b5
set listchars=eol:\\U000021b5
```

Note that a double backslash is used. The number of hex characters
must be exactly 2 for \\x, 4 for \\u and 8 for \\U.

Examples:

```
set lcs=tab:>-,trail:-
set lcs=tab:>-,eol:<,nbsp:%
set lcs=extends:>,precedes:<
```

hl-NonText highlighting will be used for "eol", "extends" and
"precedes". hl-Whitespace for "nbsp", "space", "tab", "multispace",
"lead" and "trail".

'loadplugins' 'lpl' 'noloadplugins' 'nolpl'
'loadplugins' 'lpl' boolean (default on)
global
When on the plugin scripts are loaded when starting up load-plugins.
This option can be reset in your vimrc file to disable the loading
of plugins.
Note that using the "-u NONE" and "--noplugin" command line arguments
reset this option. -u --noplugin

'makeef' 'mef'
'makeef' 'mef' string (default "")
global
Disallowed in modeline. no-modeline-option
Name of the errorfile for the :make command (see :make_makeprg)
and the :grep command.
When it is empty, an internally generated temp file will be used.
When "##" is included, it is replaced by a number to make the name
unique. This makes sure that the ":make" command doesn't overwrite an
existing file.
NOT used for the ":cf" command. See 'errorfile' for that.
Environment variables are expanded :set_env.
See option-backslash about including spaces and backslashes.

'makeencoding' 'menc'
'makeencoding' 'menc' string (default "")
global or local to buffer global-local
Encoding used for reading the output of external commands. When
empty, encoding is not converted.
This is used for :make, :lmake, :grep, :lgrep, :grepadd,
:lgrepadd, :cfile, :cgetfile, :caddfile, :lfile, :lgetfile,
and :laddfile.

This would be mostly useful when you use MS-Windows. If iconv is
enabled, setting 'makeencoding' to "char" has the same effect as
setting to the system locale encoding. Example:

```
set makeencoding=char   " system locale is used
```

'makeprg' 'mp'
'makeprg' 'mp' string (default "make")
global or local to buffer global-local
Disallowed in modeline. no-modeline-option
Program to use for the ":make" command. See :make_makeprg.
This option may contain '%' and '#' characters (see :_% and :_#),
which are expanded to the current and alternate file name. Use ::S
to escape file names in case they contain special characters.
Environment variables are expanded :set_env. See option-backslash
about including spaces and backslashes.
Note that a '|' must be escaped twice: once for ":set" and once for
the interpretation of a command. When you use a filter called
"myfilter" do it like this:

```
set makeprg=gmake\ \\\|\ myfilter
```

The placeholder "$*" can be given (even multiple times) to specify
where the arguments will be included, for example:

```
set makeprg=latex\ \\\\nonstopmode\ \\\\input\\{$*}
```

'matchpairs' 'mps'

'matchpairs' 'mps'	string	(default "(:),{:},[:]")
		local to buffer
	Characters that form pairs. The % command jumps from one to the
	other.
	Only character pairs are allowed that are different, thus you cannot
	jump between two double quotes.
	The characters must be separated by a colon.
	The pairs must be separated by a comma. Example for including '<' and
	'>' (for HTML):

```
set mps+=<:>
```

	A more exotic example, to jump between the '=' and ';' in an
	assignment, useful for languages like C and Java:

```
au FileType c,cpp,java set mps+==:;
```

	For a more advanced way of using "%", see the matchit.vim plugin in
	the $VIMRUNTIME/plugin directory. add-local-help

'matchtime' 'mat'

'matchtime' 'mat'	number	(default 5)
		global
	Tenths of a second to show the matching paren, when 'showmatch' is
	set. Note that this is not in milliseconds, like other options that
	set a time. This is to be compatible with Nvi.

'maxfuncdepth' 'mfd'

'maxfuncdepth' 'mfd'	number	(default 100)
		global
	Maximum depth of function calls for user functions. This normally
	catches endless recursion. When using a recursive function with
	more depth, set 'maxfuncdepth' to a bigger number. But this will use
	more memory, there is the danger of failing when memory is exhausted.
	Increasing this limit above 200 also changes the maximum for Ex
	command recursion, see E169.
	See also :function.
	Also used for maximum depth of callback functions.

'maxmapdepth' 'mmd' E223

'maxmapdepth' 'mmd'	number	(default 1000)
		global
	Maximum number of times a mapping is done without resulting in a
	character to be used. This normally catches endless mappings, like
	":map x y" with ":map y x". It still does not catch ":map g wg",
	because the 'w' is used before the next mapping is done. See also
	key-mapping.

'maxmempattern' 'mmp'

'maxmempattern' 'mmp'	number	(default 1000)
		global
	Maximum amount of memory (in Kbyte) to use for pattern matching.
	The maximum value is about 2000000. Use this to work without a limit.
E363

	When Vim runs into the limit it gives an error message and mostly
	behaves like CTRL-C was typed.
	Running into the limit often means that the pattern is very
	inefficient or too complex. This may already happen with the pattern
	\(.\)* on a very long line. .* works much better.
	Might also happen on redraw, when syntax rules try to match a complex
	text structure.
	Vim may run out of memory before hitting the 'maxmempattern' limit, in
	which case you get an "Out of memory" error instead.

'maxsearchcount' 'msc'

'maxsearchcount' 'msc'	number	(default 999)
		global
	Maximum number of matches shown for the search count status shm-S
	When the number of matches exceeds this value, Vim shows ">" instead
	of the exact count to keep searching fast.
	Note: larger values may impact performance.
	The value must be between 1 and 9999. See also the searchcount()
	function.

'menuitems' 'mis'

'menuitems' 'mis'	number	(default 25)
		global
	Maximum number of items to use in a menu. Used for menus that are
	generated from a list of items, e.g., the Buffers menu. Changing this
	option has no direct effect, the menu must be refreshed first.

'messagesopt' 'mopt'

'messagesopt' 'mopt'	string	(default "hit-enter,history:500,progress:c")
		global
	Option settings for outputting messages. It can consist of the
	following items. Items must be separated by a comma.

	history:{n}	Determines how many entries are remembered in the
			:messages history. The maximum value is 10000.
			Setting it to zero clears the message history.
			This item must always be present.

hit-enter	Use a hit-enter prompt when the message is longer than 'cmdheight' size.

maxheight:{n}	ui2 only. Maximum height of the expanded cmdline for message display, as a percentage of 'lines'. A message longer than this is "collapsed", with a [+x] "spill" indicator. (default: 50)

pager:{key}	ui2 only. Key that enters the message pager after an interactive : command showed a collapsed message. Use key-notation, e.g. <CR>. A literal comma must be given as "<Char-44>". Empty: no such key.

progress:{s}	Determines where to show progress messages. Valid values are:

- empty: Progress messages not shown in cmdline.
- "c": Progress messages are shown in cmdline.

timeout:{n}	ui2 only. Time in milliseconds that a message is visible in the message window.

wait:{n}	**Deprecated** with ui2. Instead of a hit-enter prompt, simply wait for {n} milliseconds so the user has a chance to read the message. Maximum {n} is 10000. Use 0 to disable the wait (user won't see any "hit-enter" messages). Ignored when "hit-enter" is present, but required when "hit-enter" is not present.

'mkspellmem' 'msm'

'mkspellmem' 'msm'	string (default "460000,2000,500")
global
Disallowed in modeline. no-modeline-option

Parameters for :mkspell. This tunes when to start compressing the word tree. Compression can be slow when there are many words, but it's needed to avoid running out of memory. The amount of memory used per word depends very much on how similar the words are, that's why this tuning is complicated.

There are three numbers, separated by commas:

```
{start},{inc},{added}
```

For most languages the uncompressed word tree fits in memory. {start} gives the amount of memory in Kbyte that can be used before any compression is done. It should be a bit smaller than the amount of memory that is available to Vim.

When going over the {start} limit the {inc} number specifies the amount of memory in Kbyte that can be allocated before another compression is done. A low number means compression is done after less words are added, which is slow. A high number means more memory will be allocated.

After doing compression, {added} times 1024 words can be added before the {inc} limit is ignored and compression is done when any extra amount of memory is needed. A low number means there is a smaller chance of hitting the {inc} limit, less memory is used but it's slower.

The languages for which these numbers are important are Italian and Hungarian. The default works for when you have about 512 Mbyte. If you have 1 Gbyte you could use:

```
set mkspellmem=900000,3000,800
```

If you have less than 512 Mbyte :mkspell may fail for some languages, no matter what you set 'mkspellmem' to.
Environment variables are expanded :set_env.

'modeline' 'ml' 'nomodeline' 'noml'

'modeline' 'ml'	boolean (default on (off for root))
local to buffer

If 'modeline' is on 'modelines' gives the number of lines that is checked for set commands. If 'modeline' is off or 'modelines' is zero no lines are checked. See modeline.

'modelineexpr' 'mle' 'nomodelineexpr' 'nomle'

'modelineexpr' 'mle'	boolean (default off)
global
Disallowed in modeline. no-modeline-option

When on allow some options that are an expression to be set in the modeline. Check the option for whether it is affected by 'modelineexpr'. Also see modeline.

'modelines' 'mls'

'modelines' 'mls'	number (default 5)
global

If 'modeline' is on 'modelines' gives the number of lines that is checked for set commands. If 'modeline' is off or 'modelines' is zero no lines are checked. See modeline.

'modifiable' 'ma' 'nomodifiable' 'noma' E21

'modifiable' 'ma'	boolean (default on)

local to buffer
When off the buffer contents cannot be changed. The 'fileformat' and 'fileencoding' options also can't be changed.
Can be reset on startup with the -M command line argument.

'modified' 'mod' 'nomodified' 'nomod'
'modified' 'mod' boolean (default off)
local to buffer local-noglobal
When on, the buffer is considered to be modified. This option is set when:
1. A change was made to the text since it was last written. Using the undo command to go back to the original text will reset the option. But undoing changes that were made before writing the buffer will set the option again, since the text is different from when it was written.
2. 'fileformat' or 'fileencoding' is different from its original value. The original value is set when the buffer is read or written. A ":set nomodified" command also resets the original values to the current values and the 'modified' option will be reset.
Similarly for 'eol' and 'bomb'.
This option is not set when a change is made to the buffer as the result of a BufNewFile, BufRead/BufReadPost, BufWritePost, FileAppendPost or VimLeave autocommand event. See gzip-example for an explanation.

When 'buftype' is "prompt", 'modified' is not implicitly set when the buffer is changed, but a user or plugin may explicitly set it.

When 'buftype' is "nowrite" or "nofile", this option may be set, but will be ignored.

Note that the text may actually be the same, e.g. 'modified' is set when using "rA" on an "A".

'more' 'nomore'
'more' boolean (default on)
global
When on, listings pause when the whole screen is filled. You will get the more-prompt. When this option is off there are no pauses, the listing continues until finished.

'mouse'

'mouse' string (default "nvi")
global
Enables mouse support. For example, to enable the mouse in Normal mode and Visual mode:

```
set mouse=nv
```

To temporarily disable mouse support, hold the shift key while using the mouse.

Mouse support can be enabled for different modes:
n Normal mode
v Visual mode
i Insert mode
c Command-line mode
h all previous modes when editing a help file
a all previous modes
r for hit-enter and more-prompt prompt

Left-click anywhere in a text buffer to place the cursor there. This works with operators too, e.g. type d then left-click to delete text from the current cursor position to the position where you clicked.

Drag the status-line or vertical separator of a window to resize it.

If enabled for "v" (Visual mode) then double-click selects word-wise, triple-click makes it line-wise, and quadruple-click makes it rectangular block-wise.

For scrolling with a mouse wheel see scroll-mouse-wheel.

Note: When enabling the mouse in a terminal, copy/paste will use the "* register if possible. See also 'clipboard'.

Related options:
'mousefocus' window focus follows mouse pointer
'mousemodel' what mouse button does which action
'mousehide' hide mouse pointer while typing text
'selectmode' whether to start Select mode or Visual mode

'mousefocus' 'mousef' 'nomousefocus' 'nomousef'
'mousefocus' 'mousef' boolean (default off)
global
The window that the mouse pointer is on is automatically activated. When changing the window layout or window focus in another way, the mouse pointer is moved to the window with keyboard focus. Off is the default because it makes using the pull down menus a little goofy, as a pointer transit may activate a window unintentionally.

'mousehide' 'mh' 'nomousehide' 'nomh'

'mousehide' 'mh' boolean (default on)
global
only in the GUI

When on, the mouse pointer is hidden when characters are typed.
The mouse pointer is restored when the mouse is moved.

'mousemodel' 'mousem'

'mousemodel' 'mousem' string (default "popup_setpos")
global

Sets the model to use for the mouse. The name mostly specifies what the right mouse button is used for:

- extend — Right mouse button extends a selection. This works like in an xterm.
- popup — Right mouse button pops up a menu. The shifted left mouse button extends a selection. This works like with Microsoft Windows.
- popup_setpos — Like "popup", but the cursor will be moved to the position where the mouse was clicked, and thus the selected operation will act upon the clicked object. If clicking inside a selection, that selection will be acted upon, i.e. no cursor move. This implies of course, that right clicking outside a selection will end Visual mode.

For a detailed description of 'mousemodel' behaviour see mouse-mode-table. Overview of what button does what for each model:

mouse	extend	popup(_setpos)
left click	place cursor	place cursor
left drag	start selection	start selection
shift-left	search word	extend selection
right click	extend selection	popup menu (place cursor)
right drag	extend selection	-
middle click	paste	paste

In the "popup" model the right mouse button produces a pop-up menu. Nvim creates a default popup-menu but you can redefine it.

Note that you can further refine the meaning of buttons with mappings. See mouse-overview. But mappings are NOT used for modeless selection.

Example:

```
map <S-LeftMouse>     <RightMouse>
map <S-LeftDrag>      <RightDrag>
map <S-LeftRelease>   <RightRelease>
map <2-S-LeftMouse>   <2-RightMouse>
map <2-S-LeftDrag>    <2-RightDrag>
map <2-S-LeftRelease> <2-RightRelease>
map <3-S-LeftMouse>   <3-RightMouse>
map <3-S-LeftDrag>    <3-RightDrag>
map <3-S-LeftRelease> <3-RightRelease>
map <4-S-LeftMouse>   <4-RightMouse>
map <4-S-LeftDrag>    <4-RightDrag>
map <4-S-LeftRelease> <4-RightRelease>
```

Mouse commands requiring the CTRL modifier can be simulated by typing the "g" key before using the mouse:

```
"g<LeftMouse>"  is "<C-LeftMouse>   (jump to tag under mouse click)
"g<RightMouse>" is "<C-RightMouse>  ("CTRL-T")
```

'mousemoveevent' 'mousemev' 'nomousemoveevent' 'nomousemev' mouse-hover

'mousemoveevent' 'mousemev' boolean (default off)
global

When on, mouse move events are delivered to the input queue and are available for mapping <MouseMove>. The default, off, avoids the mouse movement overhead except when needed.
Warning: Setting this option can make pending mappings to be aborted when the mouse is moved.

'mousescroll' E5080

'mousescroll' string (default "ver:3,hor:6")
global

This option controls the number of lines / columns to scroll by when scrolling with a mouse wheel (scroll-mouse-wheel). The option is a comma-separated list. Each part consists of a direction and a count as follows:

```
direction:count,direction:count
```

Direction is one of either "hor" or "ver". "hor" controls horizontal scrolling and "ver" controls vertical scrolling. Count sets the amount to scroll by for the given direction, it should be a non negative integer. Each direction should be set at most once. If a direction is omitted, a default value is used (6 for horizontal scrolling and 3 for vertical scrolling). You can disable mouse scrolling by using a count of 0.

Example:

```
set mousescroll=ver:5,hor:2
```

Will make Nvim scroll 5 lines at a time when scrolling vertically, and scroll 2 columns at a time when scrolling horizontally.

'mousetime' 'mouset'

'mousetime' 'mouset'	number (default 500)
global

Defines the maximum time in msec between two mouse clicks for the second click to be recognized as a multi click.

'nrformats' 'nf'

'nrformats' 'nf'	string (default "bin,hex")
local to buffer

This defines what bases Vim will consider for numbers when using the CTRL-A and CTRL-X commands for adding to and subtracting from a number respectively; see CTRL-A for more info on these commands.

alpha	If included, single alphabetical characters will be incremented or decremented. This is useful for a list with a letter index a), b), etc.

octal-nrformats

octal	If included, numbers that start with a zero will be considered to be octal. Example: Using CTRL-A on "007" results in "010".

hex	If included, numbers starting with "0x" or "0X" will be considered to be hexadecimal. Example: Using CTRL-X on "0x100" results in "0x0ff".

bin	If included, numbers starting with "0b" or "0B" will be considered to be binary. Example: Using CTRL-X on "0b1000" subtracts one, resulting in "0b0111".

unsigned	If included, numbers are recognized as unsigned. Thus a leading dash or negative sign won't be considered as part of the number. Examples:
Using CTRL-X on "2020" in "9-2020" results in "9-2019" (without "unsigned" it would become "9-2021").
Using CTRL-A on "2020" in "9-2020" results in "9-2021" (without "unsigned" it would become "9-2019").
Using CTRL-X on "0" or CTRL-A on "18446744073709551615" (2^64 - 1) has no effect, overflow is prevented.

blank	If included, treat numbers as signed or unsigned based on preceding whitespace. If a number with a leading dash has its dash immediately preceded by a non-whitespace character (i.e., not a tab or a " "), the negative sign won't be considered as part of the number. For example:
Using CTRL-A on "14" in "Carbon-14" results in "Carbon-15" (without "blank" it would become "Carbon-13").
Using CTRL-X on "8" in "Carbon -8" results in "Carbon -9" (because -8 is preceded by whitespace. If "unsigned" was set, it would result in "Carbon -7").
If this format is included, overflow is prevented as if "unsigned" were set. If both this format and "unsigned" are included, "unsigned" will take precedence.

Numbers which simply begin with a digit in the range 1-9 are always considered decimal. This also happens for numbers that are not recognized as octal or hex.

'number' 'nu' 'nonumber' 'nonu'

'number' 'nu'	boolean (default off)
local to window

Print the line number in front of each line. When the 'n' option is excluded from 'cpoptions' a wrapped line will not use the column of line numbers.
Use the 'numberwidth' option to adjust the room for the line number.
When a long, wrapped line doesn't start with the first character, '-' characters are put before the number.
For highlighting see hl-LineNr, hl-CursorLineNr, and the :sign-define "numhl" argument.

number_relativenumber

The 'relativenumber' option changes the displayed number to be relative to the cursor. Together with 'number' there are these four combinations (cursor in line 3):

'nonu'	'nu'	'nonu'	'nu'
'nornu'	'nornu'	'rnu'	'rnu'

```
|apple          |  1 apple      |  2 apple      |  2 apple
|pear           |  2 pear       |  1 pear       |  1 pear
|nobody         |  3 nobody     |  0 nobody     |3   nobody
|there          |  4 there      |  1 there      |  1 there
```

'numberwidth' 'nuw'

'numberwidth' 'nuw'	number (default 4)
local to window

Minimal number of columns to use for the line number. Only relevant when the 'number' or 'relativenumber' option is set or printing lines with a line number. Since one space is always between the number and the text, there is one less character for the number itself.
The value is the minimum width. A bigger width is used when needed to fit the highest line number in the buffer respectively the number of rows in the window, depending on whether 'number' or 'relativenumber' is set. Thus with the Vim default of 4 there is room for a line number up to 999. When the buffer has 1000 lines five columns will be used. The minimum value is 1, the maximum value is 20.

'omnifunc' 'ofu'

'omnifunc' 'ofu'	string	(default "")
			local to buffer
			Disallowed in modeline. no-modeline-option
	This option specifies a function to be used for Insert mode omni
	completion with CTRL-X CTRL-O. i_CTRL-X_CTRL-O
	See complete-functions for an explanation of how the function is
	invoked and what it should return. The value can be the name of a
	function, a lambda or a Funcref. See option-value-function for
	more information.
	This option is usually set by a filetype plugin:
	:filetype-plugin-on

'operatorfunc' 'opfunc'

'operatorfunc' 'opfunc' string	(default "")
			global
			Disallowed in modeline. no-modeline-option
	This option specifies a function to be called by the g@ operator.
	See :map-operator for more info and an example. The value can be
	the name of a function, a lambda or a Funcref. See
	option-value-function for more information.

'packlockfile' 'plf'

'packlockfile' 'plf'	string	(default "$XDG_CONFIG_HOME/nvim/nvim-pack-lock.json")
			global
			Disallowed in modeline. no-modeline-option
	Path of vim.pack-lockfile. Must be set before the first usage of any
	vim.pack function. Environment variables are expanded :set_env.

'packpath' 'pp'

'packpath' 'pp'		string	(default see 'runtimepath')
			global
			Disallowed in modeline. no-modeline-option
	Directories used to find packages.
	See packages and packages-runtimepath.
	Environment variables are expanded :set_env.

'paragraphs' 'para'

'paragraphs' 'para'	string	(default "IPLPPPQPP TPHPLIPpLpItpplpipbp")
			global
	Specifies the nroff macros that separate paragraphs. These are pairs
	of two letters (see object-motions).

'patchexpr' 'pex'

'patchexpr' 'pex'	string	(default "")
			global
			Disallowed in modeline. no-modeline-option
	Expression which is evaluated to apply a patch to a file and generate
	the resulting new version of the file. See diff-patchexpr.

'patchmode' 'pm' E205 E206

'patchmode' 'pm'	string	(default "")
			global
	When non-empty the oldest version of a file is kept. This can be used
	to keep the original version of a file if you are changing files in a
	source distribution. Only the first time that a file is written a
	copy of the original file will be kept. The name of the copy is the
	name of the original file with the string in the 'patchmode' option
	appended. This option should start with a dot. Use a string like
	".orig" or ".org". 'backupdir' must not be empty for this to work
	(Detail: The backup file is renamed to the patchmode file after the
	new file has been successfully written, that's why it must be possible
	to write a backup file). If there was no file to be backed up, an
	empty file is created.
	When the 'backupskip' pattern matches, a patchmode file is not made.
	Using 'patchmode' for compressed files appends the extension at the
	end (e.g., "file.gz.orig"), thus the resulting name isn't always
	recognized as a compressed file.
	Only normal file name characters can be used, /*?[|<> are illegal.

'path' 'pa' E343 E345 E347 E854

'path' 'pa'		string	(default ".,,")
			global or local to buffer global-local
	This is a list of directories which will be searched when using the
	gf, [f,]f, ^Wf, :find, :sfind, :tabfind and other commands,
	provided that the file being searched for has a relative path (not
	starting with "/", "./" or "../"). The directories in the 'path'
	option may be relative or absolute.

- Use commas to separate directory names:

```
set path=.,/usr/local/include,/usr/include
```

- Spaces can also be used to separate directory names. To have a

  space in a directory name, precede it with an extra backslash, and
  escape the space:

```
set path=.,/dir/with\\\ space
```

- To include a comma in a directory name precede it with an extra

backslash:

```
set path=.,/dir/with\\,comma
```

- To search relative to the directory of the current file, use:

```
set path=.
```

- To search in the current directory use an empty string between two

commas:

```
set path=,,
```

- A directory name may end in a ':' or '/'.

- Environment variables are expanded :set_env.

- When using netrw URLs can be used. For example, adding

"https://www.vim.org" will make ":find index.html" work.
- Search upwards and downwards in a directory tree using "*", "**" and

";". See file-searching for info and syntax.
- Careful with '\' characters, type two to get one in the option:

```
set path=.,c:\\include
```

Or just use '/' instead:

```
set path=.,c:/include
```

Don't forget "." or files won't even be found in the same directory as
the file!
The maximum length is limited. How much depends on the system, mostly
it is something like 256 or 1024 characters.
You can check if all the include files are found, using the value of
'path', see :checkpath.
The use of :set+= and :set-= is preferred when adding or removing
directories from the list. This avoids problems when a future version
uses another default. To remove the current directory use:

```
set path-=
```

To add the current directory use:

```
set path+=
```

To use an environment variable, you probably need to replace the
separator. Here is an example to append $INCL, in which directory
names are separated with a semicolon:

```
let &path = &path .. "," .. substitute($INCL, ';', ',', 'g')
```

Replace the ';' with a ':' or whatever separator is used. Note that
this doesn't work when $INCL contains a comma or white space.

'preserveindent' 'pi' 'nopreserveindent' 'nopi'
'preserveindent' 'pi'   boolean (default off)
local to buffer
When changing the indent of the current line, preserve as much of the
indent structure as possible. Normally the indent is replaced by a
series of tabs followed by spaces as required (unless 'expandtab' is
enabled, in which case only spaces are used). Enabling this option
means the indent will preserve as many existing characters as possible
for indenting, and only add additional tabs or spaces as required.
'expandtab' does not apply to the preserved white space, a Tab remains
a Tab.
NOTE: When using ">>" multiple times the resulting indent is a mix of
tabs and spaces. You might not like this.
Also see 'copyindent'.
Use :retab to clean up white space.

'previewheight' 'pvh'
'previewheight' 'pvh'   number (default 12)
global
Default height for a preview window. Used for :ptag and associated
commands. Used for CTRL-W_} when no count is given.

'previewpopup' 'pvp'
'previewpopup' 'pvp'   string (default "")
global

When not empty a floating window is used for commands that would open a preview window. See preview-popup.
The option is a comma-separated list of these items:
   height Height of the window. When omitted, it is derived from the content.
   width   Width of the window. When omitted, it is derived from the content.
   border One of the 'winborder' styles. When omitted, 'winborder' is used. A custom (comma separated) border cannot be given here, use 'winborder'.
The window background uses hl-NormalFloat and the border uses hl-FloatBorder.
Not used for the insert completion info, add "popup" to 'completeopt' for that.

Example:

```
set previewpopup=height:10,width:60,border:rounded
```

'previewwindow' 'pvw' 'nopreviewwindow' 'nopvw' E590
'previewwindow' 'pvw' boolean (default off)
local to window local-noglobal
Identifies the preview window. Only one window can have this option set. It's normally not set directly, but by using one of the commands :ptag, :pedit, etc.

'pumblend' 'pb'
'pumblend' 'pb' number (default 0)
global
Enables pseudo-transparency for the popup-menu. Valid values are in the range of 0 for fully opaque popupmenu (disabled) to 100 for fully transparent background. Values between 0-30 are typically most useful.

It is possible to override the level for individual highlights within the popupmenu using highlight-blend. For instance, to enable transparency but force the current selected element to be fully opaque:

```
set pumblend=15
hi PmenuSel blend=0
```

UI-dependent. Works best with RGB colors. 'termguicolors'

'pumborder'

'pumborder' string (default "")
global
Defines the default border style of popupmenu windows. See 'winborder' for valid values. hl-PmenuBorder is used for highlighting the border, and when style is "shadow" the hl-PmenuShadow and hl-PmenuShadowThrough groups are used.

This option also applies to mouse popup menus when 'mousemodel' is set to "popup" or "popup_setpos", which will display borders using the same style.

'pumheight' 'ph'
'pumheight' 'ph' number (default 0)
global
Maximum number of items to show in the popup menu (ins-completion-menu). Zero means "use available screen space".

'pummaxwidth' 'pmw'
'pummaxwidth' 'pmw' number (default 0)
global
Maximum width for the popup menu (ins-completion-menu). When zero, there is no maximum width limit, otherwise the popup menu will never be wider than this value. Truncated text will be indicated by "trunc" value of 'fillchars' option.

This option takes precedence over 'pumwidth'.

'pumwidth' 'pw'
'pumwidth' 'pw' number (default 15)
global
Minimum width for the popup menu (ins-completion-menu). If the cursor column + 'pumwidth' exceeds screen width, the popup menu is nudged to fit on the screen.

'pyxversion' 'pyx'
'pyxversion' 'pyx' number (default 3)
global
Disallowed in modeline. no-modeline-option
Specifies the python version used for pyx* functions and commands python_x. As only Python 3 is supported, this always has the value 3. Setting any other value is an error.

'quickfixtextfunc' 'qftf'
'quickfixtextfunc' 'qftf' string (default "")
global
Disallowed in modeline. no-modeline-option
This option specifies a function to be used to get the text to display in the quickfix and location list windows. This can be used to customize the information displayed in the quickfix or location window for each entry in the corresponding quickfix or location list. See quickfix-window-function for an explanation of how to write the function and an example. The value can be the name of a function, a

lambda or a Funcref. See option-value-function for more information.

It is not allowed to change text or jump to another window while evaluating 'gftf' textlock.

'quoteescape' 'qe'

'quoteescape' 'qe' string (default "\")
local to buffer

The characters that are used to escape quotes in a string. Used for objects like a', a" and a` a'.
When one of the characters in this option is found inside a string, the following character will be skipped. The default value makes the text "foo\"bar\\" considered to be one string.

'readonly' 'ro' 'noreadonly' 'noro'

'readonly' 'ro' boolean (default off)
local to buffer local-noglobal

If on, writes fail unless you use a '!'. Protects you from accidentally overwriting a file. Default on when Vim is started in read-only mode ("vim -R") or when the executable is called "view".
When using ":w!" the 'readonly' option is reset for the current buffer, unless the 'Z' flag is in 'cpoptions'.
When using the ":view" command the 'readonly' option is set for the newly edited buffer.
See 'modifiable' for disallowing changes to the buffer.

'redrawdebug' 'rdb'

'redrawdebug' 'rdb' string (default "")
global

Flags to change the way redrawing works, for debugging purposes.
Most useful with 'writedelay' set to some reasonable value.
Supports the following flags:

compositor	Indicate each redraw event handled by the compositor by briefly flashing the redrawn regions in colors indicating the redraw type. These are the highlight groups used (and their default colors):		
	RedrawDebugNormal	gui=reverse	normal redraw passed through
	RedrawDebugClear	guibg=Yellow	clear event passed through
	RedrawDebugComposed	guibg=Green	redraw event modified by the compositor (due to overlapping grids, etc)
	RedrawDebugRecompose	guibg=Red	redraw generated by the compositor itself, due to a grid being moved or deleted.
line	introduce a delay after each line drawn on the screen. When using the TUI or another single-grid UI, "compositor" gives more information and should be preferred (every line is processed as a separate event by the compositor)		
flush	introduce a delay after each "flush" event.		
nothrottle	Turn off throttling of the message grid. This is an optimization that joins many small scrolls to one larger scroll when drawing the message area (with 'display' msgsep flag active).		
invalid	Enable stricter checking (abort) of inconsistencies of the internal screen state. This is mostly useful when running nvim inside a debugger (and the test suite).		
nodelta	Send all internally redrawn cells to the UI, even if they are unchanged from the already displayed state.		

'redrawtime' 'rdt'

'redrawtime' 'rdt' number (default 2000)
global

Time in milliseconds for redrawing the display. Applies to 'hlsearch', 'inccommand', :match highlighting, syntax highlighting, and async LanguageTree:parse().
When redrawing takes more than this many milliseconds no further matches will be highlighted.
For syntax highlighting the time applies per window. When over the limit syntax highlighting is disabled until CTRL-L is used.
This is used to avoid that Vim hangs when using a very complicated pattern.

'regexpengine' 're'

'regexpengine' 're' number (default 0)
global

This selects the default regexp engine. two-engines
The possible values are:

0	automatic selection
1	old engine
2	NFA engine

Note that when using the NFA engine and the pattern contains something that is not supported the pattern will not match. This is only useful for debugging the regexp engine.
Using automatic selection enables Vim to switch the engine, if the default engine becomes too costly. E.g., when the NFA engine uses too many states. This should prevent Vim from hanging on a combination of a complex pattern with long text.

'relativenumber' 'rnu' 'norelativenumber' 'nornu'

'relativenumber' 'rnu' boolean (default off)
local to window

Show the line number relative to the line with the cursor in front of

each line. Relative line numbers help you use the count you can
precede some vertical motion commands (e.g. j k + -) with, without
having to calculate it yourself. Especially useful in combination
with other commands (e.g. y d c < > gq gw =).
When the 'n' option is excluded from 'cpoptions' a wrapped line will
not use the column of line numbers.
The 'numberwidth' option can be used to set the room used for the line
number.
When a long, wrapped line doesn't start with the first character, '-'
characters are put before the number.
See hl-LineNr and hl-CursorLineNr for the highlighting used for
the number.

The number in front of the cursor line also depends on the value of
'number', see number_relativenumber for all combinations of the two
options.

'report'

'report'		number (default 2)
		global
	Threshold for reporting number of lines changed. When the number of
	changed lines is more than 'report' a message will be given for most
	":" commands. If you want it always, set 'report' to 0.
	For the ":substitute" command the number of substitutions is used
	instead of the number of lines.

			'revins' 'ri' 'norevins' 'nori'
'revins' 'ri'		boolean (default off)
		global
	Inserting characters in Insert mode will work backwards. See "typing
	backwards" ins-reverse. This option can be toggled with the CTRL-_
	command in Insert mode, when 'allowrevins' is set.

			'rightleft' 'rl' 'norightleft' 'norl'
'rightleft' 'rl'	boolean (default off)
		local to window
	When on, display orientation becomes right-to-left, i.e., characters
	that are stored in the file appear from the right to the left.
	Using this option, it is possible to edit files for languages that
	are written from the right to the left such as Hebrew and Arabic.
	This option is per window, so it is possible to edit mixed files
	simultaneously, or to view the same file in both ways (this is
	useful whenever you have a mixed text file with both right-to-left
	and left-to-right strings so that both sets are displayed properly
	in different windows). Also see rileft.txt.

					'rightleftcmd' 'rlc'
'rightleftcmd' 'rlc'	string (default "search")
		local to window
	Each word in this option enables the command line editing to work in
	right-to-left mode for a group of commands:

		search		"/" and "?" commands

	This is useful for languages such as Hebrew, Arabic and Farsi.
	The 'rightleft' option must be set for 'rightleftcmd' to take effect.

				'ruler' 'ru' 'noruler' 'noru'
'ruler' 'ru'		boolean (default on)
		global
	When on, show some buffer information in the ruler. Each window has
	its own ruler. The ruler of the active window is shown in the last
	line of the screen, unless 'cmdheight' is zero, or the window has a
	status line, which (by default) contains the window's ruler.

	'rulerformat' determines the contents of the ruler.
	By default, the line and column number of the current cursor position
	are shown, separated by a comma.
	If the number of characters displayed is different from the number of
	bytes in the text (e.g., for a TAB or a multibyte character), both
	the text column (byte number) and the screen column are shown,
	separated with a dash.
	For an empty line "0-1" is shown.
	For an empty buffer the line number will also be zero: "0,0-1".
	Finally, the relative position of the displayed text in the file is
	shown on the far right:
		Top	first line is visible
		Bot	last line is visible
		All	first and last line are visible
		45%	relative position in the file

	If you don't want to see the ruler all the time but want to know where
	you are, use "g CTRL-G" g_CTRL-G.
	When 'ruler' is on, the output of CTRL-G doen't contain the current
	line number of the cursor position.

					'rulerformat' 'ruf'
'rulerformat' 'ruf'	string (default "%18(%l,%c%V%= %P%)%<")
		global
	This option determines the content of the ruler string, as displayed
	for the 'ruler' option.
	The format of this option is like that of 'statusline'.
	Setting to empty (:set rulerformat=) sets the value to the default.
	This option cannot be set in a modeline when 'modelineexpr' is off.

	When 'ruler' is on, the default 'statusline' includes 'rulerformat'.

The default ruler width is 18 characters, which is configured with what looks like an item group. But there are some differences in this particular case. Most notably, the width is fixed and not a minimum, and the ruler is left-aligned, whereas the alignment of item groups is configurable and right-aligned by default.

When ui2 is enabled, the ruler no longer has a fixed width and the item group syntax has no special meaning for 'rulerformat'.

'runtimepath' 'rtp' vimfiles

'runtimepath' 'rtp' string (default "$XDG_CONFIG_HOME/nvim,
$XDG_CONFIG_DIRS[1]/nvim,
$XDG_CONFIG_DIRS[2]/nvim,
…
$XDG_DATA_HOME/nvim[-data]/site,
$XDG_DATA_DIRS[1]/nvim/site,
$XDG_DATA_DIRS[2]/nvim/site,
…
$VIMRUNTIME,
…
$XDG_DATA_DIRS[2]/nvim/site/after,
$XDG_DATA_DIRS[1]/nvim/site/after,
$XDG_DATA_HOME/nvim[-data]/site/after,
…
$XDG_CONFIG_DIRS[2]/nvim/after,
$XDG_CONFIG_DIRS[1]/nvim/after,
$XDG_CONFIG_HOME/nvim/after")
global
Disallowed in modeline. no-modeline-option

List of directories to be searched for these runtime files:

filetype.lua	filetypes new-filetype
autoload/	automatically loaded scripts autoload-functions
colors/	color scheme files :colorscheme
compiler/	compiler files :compiler
doc/	documentation write-local-help
ftplugin/	filetype plugins write-filetype-plugin
indent/	indent scripts indent-expression
keymap/	key mapping files mbyte-keymap
lang/	menu translations :menutrans
lsp/	LSP client configurations lsp-config
lua/	Lua plugins
menu.vim	GUI menus menu.vim
pack/	packages :packadd
parser/	treesitter syntax parsers
plugin/	plugin scripts write-plugin
queries/	treesitter queries
rplugin/	remote-plugin scripts
spell/	spell checking files spell
syntax/	syntax files mysyntaxfile
tutor/	tutorial files :Tutor

And any other file searched for with the :runtime command.

Defaults are setup to search these locations:

1. Your home directory, for personal preferences.

   Given by stdpath("config"). $XDG_CONFIG_HOME
2. Directories which must contain configuration files according to

   xdg ($XDG_CONFIG_DIRS, defaults to /etc/xdg). This also contains preferences from system administrator.
3. Data home directory, for plugins installed by user.

   Given by stdpath("data")/site. $XDG_DATA_HOME
4. nvim/site subdirectories for each directory in $XDG_DATA_DIRS.

   This is for plugins which were installed by system administrator, but are not part of the Nvim distribution. XDG_DATA_DIRS defaults to /usr/local/share/:/usr/share/, so system administrators are expected to install site plugins to /usr/share/nvim/site.
5. $VIMRUNTIME, for files distributed with Nvim.

after-directory

   6, 7, 8, 9. In after/ subdirectories of 1, 2, 3 and 4, with reverse ordering. This is for preferences to overrule or add to the distributed defaults or system-wide settings (rarely needed).

packages-runtimepath

"start" packages will also be searched (runtime-search-path) for runtime files after these, though such packages are not explicitly reported in &runtimepath. But "opt" packages are explicitly added to &runtimepath by :packadd.

Note that, unlike 'path', no wildcards like "**" are allowed. Normal wildcards are allowed, but can significantly slow down searching for runtime files. For speed, use as few items as possible and avoid

wildcards.
See :runtime.
Example:

```
set runtimepath=~/vimruntime,/mygroup/vim,$VIMRUNTIME
```

This will use the directory "~/vimruntime" first (containing your
personal Nvim runtime files), then "/mygroup/vim", and finally
"$VIMRUNTIME" (the default runtime files).
You can put a directory before $VIMRUNTIME to find files which replace
distributed runtime files. You can put a directory after $VIMRUNTIME
to find files which add to distributed runtime files.

With --clean the home directory entries are not included.
Environment variables are expanded :set_env.

'scroll' 'scr'
'scroll' 'scr' number (default half the window height)
local to window local-noglobal

Number of lines to scroll with CTRL-U and CTRL-D commands. Will be
set to half the number of lines in the window when the window size
changes. This may happen when enabling the status-line or
'tabline' option after setting the 'scroll' option.
If you give a count to the CTRL-U or CTRL-D command it will
be used as the new value for 'scroll'. Reset to half the window
height with ":set scroll=0".

'scrollback' 'scbk'
'scrollback' 'scbk' number (default 10000)
local to buffer

Maximum number of lines kept beyond the visible screen. Lines at the
top are deleted if new lines exceed this limit.
Minimum is 1, maximum is 1000000.
Only in terminal and prompt-buffer buffers.

Note: Lines that are not visible and kept in terminal scrollback are not
reflown when the terminal buffer is resized horizontally.

'scrollbind' 'scb' 'noscrollbind' 'noscb'
'scrollbind' 'scb' boolean (default off)
local to window

Enables synchronized scrolling (in all windows with this option set).
Useful for comparing two versions of a file, see 'diff'.
Behavior is controlled by 'scrollopt'. See scroll-binding.

This option is (usually) reset when splitting a window to edit another
file: ":split | edit file" results in two windows with scroll-binding,
but ":split file" does not.

Note: Consider calling :syncbind on WinResized, WinEnter events
(scoped to relevant buffers).

'scrolljump' 'sj'
'scrolljump' 'sj' number (default 1)
global

Minimal number of lines to scroll when the cursor gets off the
screen (e.g., with "j"). Not used for scroll commands (e.g., CTRL-E,
CTRL-D). Useful if your terminal scrolls very slowly.
When set to a negative number from -1 to -100 this is used as the
percentage of the window height. Thus -50 scrolls half the window
height.

'scrolloff' 'so'
'scrolloff' 'so' number (default 0)
global or local to window global-local

Minimal number of screen lines to keep above and below the cursor.
This will make some context visible around where you are working. If
you set it to a very large value (999) the cursor line will always be
in the middle of the window (except at the start or end of the file,
see 'scrolloffpad', or when long lines wrap).
After using the local value, go back the global value with one of
these two:

```
setlocal scrolloff<
setlocal scrolloff=-1
```

For scrolling horizontally see 'sidescrolloff'.

'scrolloffpad' 'sop'
'scrolloffpad' 'sop' number (default 0)
global or local to window global-local

When 'scrolloff' and 'scrolloffpad' are greater than zero, allow
the cursor to remain centered when at the end of the file.
Normally, 'scrolloff' will not keep the cursor centered at the
end of the file.

A value of 0 disables this feature. Any value above 0 enables it.
For a window-local value, -1 means to use the global value.
Values below -1 are invalid.

Example:

```
:set scrolloff=99 scrolloffpad=1
```

After using the local value, go back the global value with one of
these two:

```
setlocal scrolloffpad<
setlocal scrolloffpad=-1
```

'scrollopt' 'sbo'

'scrollopt' 'sbo' string (default "ver,jump")
global
This is a comma-separated list of words that specifies how 'scrollbind' windows should behave. 'sbo' stands for ScrollBind Options.
The following words are available:
ver Bind vertical scrolling for 'scrollbind' windows
hor Bind horizontal scrolling for 'scrollbind' windows
jump Applies to the offset between two windows for vertical scrolling. This offset is the difference in the first displayed line of the bound windows. When moving around in a window, another 'scrollbind' window may reach a position before the start or after the end of the buffer. The offset is not changed though, when moving back the 'scrollbind' window will try to scroll to the desired position when possible.
When now making that window the current one, two things can be done with the relative offset:

1. When "jump" is not included, the relative offset is adjusted for the scroll position in the new current window. When going back to the other window, the new relative offset will be used.
2. When "jump" is included, the other windows are scrolled to keep the same relative offset. When going back to the other window, it still uses the same relative offset.

Also see scroll-binding.
When 'diff' mode is active there always is vertical scroll binding, even when "ver" isn't there.

'sections' 'sect'

'sections' 'sect' string (default "SHNHH HUnhsh")
global
Specifies the nroff macros that separate sections. These are pairs of two letters (See object-motions). The default makes a section start at the nroff macros ".SH", ".NH", ".H", ".HU", ".nh" and ".sh".

'selection' 'sel'

'selection' 'sel' string (default "inclusive")
global
This option defines the behavior of the selection. It is only used in Visual and Select mode.
Possible values:

value	past line	inclusive
old	no	yes
inclusive	yes	yes
exclusive	yes	no

"past line" means that the cursor is allowed to be positioned one character past the line.
"inclusive" means that the last character of the selection is included in an operation. For example, when "x" is used to delete the selection.
When "old" is used and 'virtualedit' allows the cursor to move past the end of line the line break still isn't included.
When "exclusive" is used, cursor position in visual mode will be adjusted for inclusive motions inclusive-motion-selection-exclusive.

Note:

- When "exclusive" is used and selecting from the end backwards, you cannot include the last character of a line, when starting in Normal mode and 'virtualedit' empty.
- when "exclusive" is used with a single character visual selection, Vim will behave as if the 'selection' is inclusive (in other words, you cannot visually select an empty region).

'selectmode' 'slm'

'selectmode' 'slm' string (default "")
global
This is a comma-separated list of words, which specifies when to start Select mode instead of Visual mode, when a selection is started.
Possible values:
mouse when using the mouse
key when using shifted special keys
cmd when using "v", "V" or CTRL-V
See Select-mode.

'sessionoptions' 'ssop'

'sessionoptions' 'ssop' string (default "blank,buffers,curdir,folds,help,tabpages,winsize,terminal")
global
Changes the effect of the :mksession command. It is a comma-

separated list of words. Each word enables saving and restoring something:

word	save and restore
blank	empty windows
buffers	hidden and unloaded buffers, not just those in windows
curdir	the current directory
folds	manually created folds, opened/closed folds and local fold options
globals	global variables that start with an uppercase letter and contain at least one lowercase letter. Only String and Number types are stored.
help	the help window
localoptions	options and mappings local to a window or buffer (not global values for local options)
options	all options and mappings (also global values for local options), except Lua functions option-value-function.
skiprtp	exclude 'runtimepath' and 'packpath' from the options
resize	size of the Vim window: 'lines' and 'columns'
sesdir	the directory in which the session file is located will become the current directory (useful with projects accessed over a network from different systems)
tabpages	all tabpages; without this only the current tabpage is restored, so that you can make a session for each tabpage separately
terminal	include terminal windows where the command can be restored
winpos	position of the whole Vim window
winsize	window sizes
slash	deprecated Always enabled. Uses "/" in filenames.
unix	deprecated Always enabled. Uses "\n" line endings.

Don't include both "curdir" and "sesdir". When neither is included filenames are stored as absolute paths.
If you leave out "options" many things won't work well after restoring the session.

'shada' 'sd' E526 E527 E528

'shada' 'sd' string (default "!,'100,<50,s10,h,r/tmp/,r/private/")
global
Disallowed in modeline. no-modeline-option

When non-empty, the shada file is read upon startup and written when exiting Vim (see shada-file). The string should be a comma-separated list of parameters, each consisting of a single character identifying the particular parameter, followed by a number or string which specifies the value of that parameter. If a particular character is left out, then the default value is used for that parameter. The following is a list of the identifying characters and the effect of their value.

CHAR	VALUE
shada-!	
!	When included, save and restore global variables that start with an uppercase letter, and don't contain a lowercase letter. Thus "KEEPTHIS and "K_L_M" are stored, but "KeepThis" and "_K_L_M" are not. Nested List and Dict items may not be read back correctly, you end up with an empty item.
shada-quote	
"	Maximum number of lines saved for each register. Old name of the '<' item, with the disadvantage that you need to put a backslash before the ", otherwise it will be recognized as the start of a comment!
shada-%	
%	When included, save and restore the buffer list. If Vim is started with a file name argument, the buffer list is not restored. If Vim is started without a file name argument, the buffer list is restored from the shada file. Quickfix ('buftype'), unlisted ('buflisted'), unnamed and buffers on removable media (shada-r) are not saved. When followed by a number, the number specifies the maximum number of buffers that are stored. Without a number all buffers are stored.
shada-'	
'	Maximum number of previously edited files for which the marks are remembered. This parameter must always be included when 'shada' is non-empty. If non-zero, then the jumplist and the changelist are also stored in the shada file.
shada-/	
/	Maximum number of items in the search pattern history to be saved. If non-zero, then the previous search and substitute patterns are also saved. When not included, the value of 'history' is used.
shada-:	
:	Maximum number of items in the command-line history to be saved. When not included, the value of 'history' is used.

shada-<

<	Maximum number of lines saved for each register. If zero then
	registers are not saved. When not included, all lines are
	saved. '"' is the old name for this item.
	Also see the 's' item below: limit specified in KiB.

shada-@

@	Maximum number of items in the input-line history to be
	saved. When not included, the value of 'history' is used.

shada-c

c	Dummy option, kept for compatibility reasons. Has no actual
	effect: ShaDa always uses UTF-8 and 'encoding' value is fixed
	to UTF-8 as well.

shada-f

f	Whether file marks need to be stored. If zero, file marks ('0
	to '9, 'A to 'Z) are not stored. When not present or when
	non-zero, they are all stored. '0 is used for the current
	cursor position (when exiting or when doing :wshada).

shada-h

h	Disable the effect of 'hlsearch' when loading the shada
	file. When not included, it depends on whether ":nohlsearch"
	has been used since the last search command.

shada-n

n	Name of the shada file. The name must immediately follow
	the 'n'. Must be at the end of the option! If the
	'shadafile' option is set, that file name overrides the one
	given here with 'shada'. Environment variables are
	expanded when opening the file, not when setting the option.

shada-r

r	Removable media. The argument is a string (up to the next
	','). This parameter can be given several times. Each
	specifies the start of a path for which no marks will be
	stored. This is to avoid removable media. For Windows you
	could use "ra:,rb:". You can also use it for temp files,
	e.g., for Unix: "r/tmp". Case is ignored.

shada-s

s	Maximum size of an item contents in KiB. If zero then nothing
	is saved. Unlike Vim this applies to all items, except for
	the buffer list and header. Full item size is off by three
	unsigned integers: with s10 maximum item size may be 1 byte
	(type: 7-bit integer) + 9 bytes (timestamp: up to 64-bit
	integer) + 3 bytes (item size: up to 16-bit integer because
	2^8 < 10240 < 2^16) + 10240 bytes (requested maximum item
	contents size) = 10253 bytes.

Example:

```
set shada='50,<1000,s100,:0,n~/nvim/shada
```

	'50		Marks will be remembered for the last 50 files you
			edited.
	<1000		Contents of registers (up to 1000 lines each) will be
			remembered.
	s100		Items with contents occupying more then 100 KiB are
			skipped.
	:0		Command-line history will not be saved.
	n~/nvim/shada	The name of the file to use is "~/nvim/shada".
	no /		Since '/' is not specified, the default will be used,
			that is, save all of the search history, and also the
			previous search and substitute patterns.
	no %		The buffer list will not be saved nor read back.
	no h		'hlsearch' highlighting will be restored.

When setting 'shada' from an empty value you can use :rshada to
load the contents of the file, this is not done automatically.

'shadafile' 'sdf'

'shadafile' 'sdf'	string (default "")
			global
			Disallowed in modeline. no-modeline-option
When non-empty, overrides the file name used for shada (viminfo).
When equal to "NONE" no shada file will be read or written.
This option can be set with the -i command line flag. The --clean
command line flag sets it to "NONE".
Environment variables are expanded :set_env.

'shell' 'sh' E91

'shell' 'sh'		string (default $SHELL or "sh", Win32: "cmd.exe")
			global
			Disallowed in modeline. no-modeline-option
Name of the shell to use for ! and :! commands. When changing the
value also check these options: 'shellpipe', 'shellslash'
'shellredir', 'shellquote', 'shellxquote' and 'shellcmdflag'.
It is allowed to give an argument to the command, e.g. "csh -f".

See option-backslash about including spaces and backslashes.
Environment variables are expanded :set_env.

If the name of the shell contains a space, you need to enclose it in quotes. Example with quotes:

```
set shell=\"c:\program\ files\unix\sh.exe\"\ -f
```

Note the backslash before each quote (to avoid starting a comment) and each space (to avoid ending the option value), so better use :let-& like this:

```
let &shell='"C:\Program Files\unix\sh.exe" -f'
```

Also note that the "-f" is not inside the quotes, because it is not part of the command name.

shell-unquoting

Rules regarding quotes:

1. Option is split on space and tab characters that are not inside quotes: "abc def" runs shell named "abc" with additional argument "def", '"abc def"' runs shell named "abc def" with no additional arguments (here and below: additional means “additional to 'shellcmdflag'”).
2. Quotes in option may be present in any position and any number: '"abc"', '"a"bc', 'a"b"c', 'ab"c"' and '"a"b"c"' are all equivalent to just "abc".
3. Inside quotes backslash preceding backslash means one backslash. Backslash preceding quote means one quote. Backslash preceding anything else means backslash and next character literally: '"a\\b"' is the same as "a\b", '"a\"b"' runs shell named literally 'a"b', '"a\b"' is the same as "a\b" again.
4. Outside of quotes backslash always means itself, it cannot be used to escape quote: 'a\"b"' is the same as "a\b".

Note that such processing is done after :set did its own round of unescaping, so to keep yourself sane use :let-& like shown above.

shell-powershell

To use PowerShell:

```
set noshelltemp
let &shell = 'powershell'
let &shellcmdflag = '-NoLogo -NoProfile -ExecutionPolicy RemoteSigned -Command '
let &shellcmdflag .= '[Console]::InputEncoding=[Console]::OutputEncoding=[System.Text.UTF8Encoding]::new();'
let &shellcmdflag .= '$PSDefaultParameterValues[''Out-File:Encoding'']=''utf8'';'
let &shellpipe  = '> %s 2>&1'
set shellquote= shellxquote=
```

shell-pwsh

To use pwsh, use the above settings with let &shell = 'pwsh', and add:

```
let &shellcmdflag .= '$PSStyle.OutputRendering = ''PlainText'';'
" Workaround (may not be needed in future version of pwsh):
let $__SuppressAnsiEscapeSequences = 1
```

'shellcmdflag' 'shcf'

'shellcmdflag' 'shcf' string (default "-c"; Windows, when 'shell' contains "cmd" somewhere: "/s /c")
global
Disallowed in modeline. no-modeline-option
Flag passed to the shell to execute "!" and ":!" commands; e.g., bash.exe -c ls or cmd.exe /s /c "dir". For MS-Windows, the default is set according to the value of 'shell', to reduce the need to set this option by the user.
On Unix it can have more than one flag. Each white space separated part is passed as an argument to the shell command.
See option-backslash about including spaces and backslashes.
See shell-unquoting which talks about separating this option into multiple arguments.

'shellpipe' 'sp'

'shellpipe' 'sp' string (default ">", "| tee", "|& tee" or "2>&1| tee")
global
Disallowed in modeline. no-modeline-option
String to be used to put the output of the ":make" command in the error file. See also :make_makeprg. See option-backslash about including spaces and backslashes.
The name of the temporary file can be represented by "%s" if necessary (the file name is appended automatically if no %s appears in the value of this option).

For MS-Windows the default is "2>&1| tee". The stdout and stderr are
saved in a file and echoed to the screen.
For Unix the default is "| tee". The stdout of the compiler is saved
in a file and echoed to the screen. If the 'shell' option contains
"csh" (e.g. "tcsh") after initializations, the default becomes
"|& tee". Otherwise, if it contains "sh" (e.g. "bash", "zsh"), the
default becomes "2>&1| tee". This means that stderr is also included.
Before using the 'shell' option a path is removed, thus "/bin/sh" uses
"sh".
The initialization of this option is done after reading the vimrc
and the other initializations, so that when the 'shell' option is set
there, the 'shellpipe' option changes automatically, unless it was
explicitly set before.
When 'shellpipe' is set to an empty string, no redirection of the
":make" output will be done. This is useful if you use a 'makeprg'
that writes to 'makeef' by itself. If you want no piping, but do
want to include the 'makeef', set 'shellpipe' to a single space.
Don't forget to precede the space with a backslash: ":set sp=\ ".
In the future pipes may be used for filtering and this option will
become obsolete (at least for Unix).
Note: When using a pipe like "| tee", you'll lose the exit code of the
shell command. This might be configurable by your shell, look for
the pipefail option (for bash and zsh, use ":set -o pipefail").
Only a single "%s" value is allowed.

'shellquote' 'shq'
'shellquote' 'shq'	string (default ""; Windows, when 'shell'
contains "sh" somewhere: "\"")
global
Disallowed in modeline. no-modeline-option
Quoting character(s), put around the command passed to the shell, for
the "!" and ":!" commands. The redirection is kept outside of the
quoting. See 'shellxquote' to include the redirection. It's
probably not useful to set both options.
This is an empty string by default. Only known to be useful for
third-party shells on Windows systems, such as the MKS Korn Shell
or bash, where it should be "\"". The default is adjusted according
the value of 'shell', to reduce the need to set this option by the
user.

'shellredir' 'srr'
'shellredir' 'srr'	string (default ">", ">&" or ">%s 2>&1")
global
Disallowed in modeline. no-modeline-option
String to be used to put the output of a filter command in a temporary
file. See also :!. See option-backslash about including spaces
and backslashes.
The name of the temporary file can be represented by "%s" if necessary
(the file name is appended automatically if no %s appears in the value
of this option).
The default is ">". For Unix, if the 'shell' option contains "csh"
(e.g. "tcsh") during initializations, the default becomes ">&".
Otherwise, if it contains "sh" (e.g. "bash", "zsh"), the default
becomes ">%s 2>&1". This means that stderr is also included. For
Win32, the Unix checks are done and additionally "cmd" is checked
for, which makes the default ">%s 2>&1".
Also, the same names with ".exe" appended are checked for.
The initialization of this option is done after reading the vimrc
and the other initializations, so that when the 'shell' option is set
there, the 'shellredir' option changes automatically unless it was
explicitly set before.
In the future pipes may be used for filtering and this option will
become obsolete (at least for Unix).

E1577

Only a single "%s" item is allowed in the option value.

'shellslash' 'ssl' 'noshellslash' 'nossl'
'shellslash' 'ssl'	boolean (default on; Windows: off, except when 'shell'
contains "sh" somewhere)
global
only modifiable in MS-Windows
When set, a forward slash is used when expanding file names. This is
useful when a Unix-like shell is used instead of cmd.exe. Backward
slashes can still be typed, but they are changed to forward slashes by
Vim.
Note that setting or resetting this option has no effect for some
existing file names, thus this option needs to be set before opening
any file for best results. This might change in the future.
'shellslash' only works when a backslash can be used as a path
separator. To test if this is so use:

```
if exists('+shellslash')
```

Also see 'completeslash'.

'shelltemp' 'stmp' 'noshelltemp' 'nostmp'
'shelltemp' 'stmp'	boolean (default off)
global
When on, use temp files for shell commands. When off use a pipe.
When using a pipe is not possible temp files are used anyway.
The advantage of using a pipe is that nobody can read the temp file

and the 'shell' command does not need to support redirection.
The advantage of using a temp file is that the file type and encoding
can be detected.
The FilterReadPre, FilterReadPost and FilterWritePre,
FilterWritePost autocommands event are not triggered when
'shelltemp' is off.
system() does not respect this option, it always uses pipes.

'shellxescape' 'sxe'
'shellxescape' 'sxe'	string (default "")
global
Disallowed in modeline. no-modeline-option
When 'shellxquote' is set to "(" then the characters listed in this
option will be escaped with a '^' character. This makes it possible
to execute most external commands with cmd.exe.

'shellxquote' 'sxq'
'shellxquote' 'sxq'	string (default ""; Windows, when 'shell'
contains "cmd" somewhere: "\"")
global
Disallowed in modeline. no-modeline-option
Quoting character(s), put around the command passed to the shell, for
the "!" and ":!" commands. Includes the redirection. See
'shellquote' to exclude the redirection. It's probably not useful
to set both options.
When the value is '(' then ')' is appended. When the value is '"('
then ')"' is appended.
When the value is '(' then also see 'shellxescape'.

'shiftround' 'sr' 'noshiftround' 'nosr'
'shiftround' 'sr'	boolean (default off)
global
Round indent to multiple of 'shiftwidth'. Applies to > and <
commands. CTRL-T and CTRL-D in Insert mode always round the indent to
a multiple of 'shiftwidth' (this is Vi compatible).

'shiftwidth' 'sw'
'shiftwidth' 'sw'	number (default 8)
local to buffer
Number of columns that make up one level of (auto)indentation. Used
by 'cindent', <<, >>, etc.
If set to 0, Vim uses the current 'tabstop' value. Use shiftwidth()
to obtain the effective value in scripts.

'shortmess' 'shm' E1336
'shortmess' 'shm'	string (default "ltToOCF")
global
Controls display of file messages (e.g. CTRL-G) and various other
messages.

It is a list of flags:

flag	meaning when present	
l	use "999L, 888B" instead of "999 lines, 888 bytes"	shm-l
m	use "[+]" instead of "[Modified]"	shm-m
r	use "[RO]" instead of "[readonly]"	shm-r
w	use "[w]" instead of "written" for file write message and "[a]" instead of "appended" for ':w >> file' command	shm-w
a	all of the above abbreviations	shm-a
o	overwrite message for writing a file with subsequent message for reading a file (useful for ":wn" or when 'autowrite' on)	shm-o
O	message for reading a file overwrites any previous message; also for quickfix message (e.g., ":cn")	shm-O
s	don't give "search hit BOTTOM, continuing at TOP" or "search hit TOP, continuing at BOTTOM" messages; when using the search count do not show "W" before the count message (see shm-S below)	shm-s
t	truncate file message at the start if it is too long to fit on the command-line, "<" will appear in the left most column; ignored in Ex mode	shm-t
T	truncate other messages in the middle if they are too long to fit on the command line; "..." will appear in the middle; ignored in Ex mode	shm-T
W	don't give "written" or "[w]" when writing a file	shm-W
A	don't give the "ATTENTION" message when an existing swap file is found	shm-A
I	don't give the intro message when starting Vim, see :intro	shm-I
c	don't give ins-completion-menu messages; for example, "-- XXX completion (YYY)", "match 1 of 2", "The only match", "Pattern not found", "Back at original", etc.	shm-c
C	don't give messages while scanning for ins-completion items, for instance "scanning tags"	shm-C
q	do not show "recording @a" when recording a macro	shm-q
F	don't give the file info when editing a file, like :silent was used for the command; note that this also affects messages from 'autoread' reloading	shm-F
S	do not show search count message when searching, e.g. "[1/5]". When the "S" flag is not present (e.g. search count	shm-S

is shown), the "search hit BOTTOM, continuing at TOP" and
"search hit TOP, continuing at BOTTOM" messages are only
indicated by a "W" (Mnemonic: Wrapped) letter before the
search count statistics. The maximum limit can be set with
the 'maxsearchcount' option, see also searchcount()
function.
u don't give undo and redo messages like shm-u

"1 line less; before #1 1 second ago", "Already at oldest
change" or "Already at newest change"

This gives you the opportunity to avoid that a change between buffers
requires you to hit <Enter>, but still gives as useful a message as
possible for the space available. To get the whole message that you
would have got with 'shm' empty, use ":file!"
Useful values:
shm= No abbreviation of message.
shm=a Abbreviation, but no loss of information.
shm=at Abbreviation, and truncate message when necessary.

'showbreak' 'sbr' E595
'showbreak' 'sbr' string (default "")
global or local to window global-local
String to put at the start of lines that have been wrapped. Useful
values are "> " or "+++ ":

```
let &showbreak = "> "
let &showbreak = '+++ '
```

Only printable single-cell characters are allowed, excluding <Tab> and
comma (in a future version the comma might be used to separate the
part that is shown at the end and at the start of a line).
The hl-NonText highlight group determines the highlighting.
Note that tabs after the showbreak will be displayed differently.
If you want the 'showbreak' to appear in between line numbers, add the
"n" flag to 'cpoptions'.
A window-local value overrules a global value. If the global value is
set and you want no value in the current window use NONE:

```
setlocal showbreak=NONE
```

'showcmd' 'sc' 'noshowcmd' 'nosc'
'showcmd' 'sc' boolean (default on)
global
Show (partial) command in the last line of the screen. Set this
option off if your terminal is slow.
In Visual mode the size of the selected area is shown:

- When selecting characters within a line, the number of characters.

  If the number of bytes is different it is also displayed: "2-6"
  means two characters and six bytes.
- When selecting more than one line, the number of lines.

- When selecting a block, the size in screen characters:

  {lines}x{columns}.
This information can be displayed in an alternative location using the
'showcmdloc' option, useful when 'cmdheight' is 0.

'showcmdloc' 'sloc'
'showcmdloc' 'sloc' string (default "last")
global
This option can be used to display the (partially) entered command in
another location. Possible values are:
last Last line of the screen (default).
statusline Status line of the current window.
tabline First line of the screen if 'showtabline' is enabled.
Setting this option to "statusline" or "tabline" means that these will
be redrawn whenever the command changes, which can be on every key
pressed.
The %S 'statusline' item can be used in 'statusline' or 'tabline' to
place the text. Without a custom 'statusline' or 'tabline' it will be
displayed in a convenient location.

'showfulltag' 'sft' 'noshowfulltag' 'nosft'
'showfulltag' 'sft' boolean (default off)
global
When completing a word in insert mode (see ins-completion) from the
tags file, show both the tag name and a tidied-up form of the search
pattern (if there is one) as possible matches. Thus, if you have
matched a C function, you can see a template for what arguments are
required (coding style permitting).
Note that this doesn't work well together with having "longest" in
'completeopt', because the completion from the search pattern may not
match the typed text.

'showmatch' 'sm' 'noshowmatch' 'nosm'
'showmatch' 'sm' boolean (default off)
global

When a bracket is inserted, briefly jump to the matching one. The jump is only done if the match can be seen on the screen. The time to show the match can be set with 'matchtime'.
A Beep is given if there is no match (no matter if the match can be seen or not).
When the 'm' flag is not included in 'cpoptions', typing a character will immediately move the cursor back to where it belongs.
See the "sm" field in 'guicursor' for setting the cursor shape and blinking when showing the match.
The 'matchpairs' option can be used to specify the characters to show matches for. 'rightleft' and 'revins' are used to look for opposite matches.
Also see the matchparen plugin for highlighting the match when moving around pi_paren.txt.
Note: Use of the short form is rated PG.

'showmode' 'smd' 'noshowmode' 'nosmd'
'showmode' 'smd' boolean (default on)
global
If in Insert, Replace or Visual mode put a message on the last line.
The hl-ModeMsg highlight group determines the highlighting.
The option has no effect when 'cmdheight' is zero.

'showtabline' 'stal'
'showtabline' 'stal' number (default 1)
global
Specifies when the tabpage labels will be displayed:
0: never
1: only if there are at least two tabpages
2: always

'sidescroll' 'ss'
'sidescroll' 'ss' number (default 1)
global
The minimal number of columns to scroll horizontally. Used only when the 'wrap' option is off and the cursor is moved off of the screen.
When it is zero the cursor will be put in the middle of the screen.
When using a slow terminal set it to a large number or 0. Not used for "zh" and "zl" commands.

'sidescrolloff' 'siso'
'sidescrolloff' 'siso' number (default 0)
global or local to window global-local
The minimal number of screen columns to keep to the left and to the right of the cursor if 'nowrap' is set. Setting this option to a value greater than 0 while having 'sidescroll' also at a non-zero value makes some context visible in the line you are scrolling in horizontally (except at beginning of the line). Setting this option to a large value (like 999) has the effect of keeping the cursor horizontally centered in the window, as long as one does not come too close to the beginning of the line.
After using the local value, go back the global value with one of these two:

```
setlocal sidescrolloff<
setlocal sidescrolloff=-1
```

Example: Try this together with 'sidescroll' and 'listchars' as in the following example to never allow the cursor to move onto the "extends" character:

```
set nowrap sidescroll=1 listchars=extends:>,precedes:<
set sidescrolloff=1
```

'signcolumn' 'scl'
'signcolumn' 'scl' string (default "auto")
local to window
When and how to draw the signcolumn. Valid values are:
"auto" only when there is a sign to display
"auto:[1-9]" resize to accommodate multiple signs up to the given number (maximum 9), e.g. "auto:4"
"auto:[1-8]-[2-9]" resize to accommodate multiple signs up to the given maximum number (maximum 9) while keeping at least the given minimum (maximum 8) fixed space. The minimum number should always be less than the maximum number, e.g. "auto:2-5"
"no" never
"yes" always
"yes:[1-9]" always, with fixed space for signs up to the given number (maximum 9), e.g. "yes:3"
"number" display signs in the 'number' column. If the number column is not present, then behaves like "auto".

'smartcase' 'scs' 'nosmartcase' 'noscs'
'smartcase' 'scs' boolean (default off)
global
Override the 'ignorecase' option if the search pattern contains upper case characters. Only used when the search pattern is typed and 'ignorecase' option is on. Used for the commands "/", "?", "n", "N", ":g" and ":s" and when filtering matches for the completion menu

compl-states.
Not used for "*", "#", "gd", tag search, etc. After "*" and "#" you can make 'smartcase' used by doing a "/" command, recalling the search pattern from history and hitting <Enter>.

'smartindent' 'si' 'nosmartindent' 'nosi'
'smartindent' 'si'	boolean (default off)
local to buffer

Do smart autoindenting when starting a new line. Works for C-like programs, but can also be used for other languages. 'cindent' does something like this, works better in most cases, but is more strict, see C-indenting. When 'cindent' is on or 'indentexpr' is set, setting 'si' has no effect. 'indentexpr' is a more advanced alternative.
Normally 'autoindent' should also be on when using 'smartindent'.
An indent is automatically inserted:

- After a line ending in "{".
- After a line starting with a keyword from 'cinwords'.
- Before a line starting with "}" (only with the "O" command).

When typing '}' as the first character in a new line, that line is given the same indent as the matching "{".
When typing '#' as the first character in a new line, the indent for that line is removed, the '#' is put in the first column. The indent is restored for the next line. If you don't want this, use this mapping: ":inoremap # X^H#", where ^H is entered with CTRL-V CTRL-H.
When using the ">>" command, lines starting with '#' are not shifted right.

'smarttab' 'sta' 'nosmarttab' 'nosta'
'smarttab' 'sta'	boolean (default on)
global

When enabled, the <Tab> key will indent by 'shiftwidth' if the cursor is in leading whitespace. The <BS> key has the opposite effect.
In leading whitespace, this has the same effect as setting 'softtabstop' to the value of 'shiftwidth'.
NOTE: in most cases, using 'softtabstop' is a better option. Have a look at section 30.5 of the user guide for detailed explanations on how Vim works with tabs and spaces.

'smoothscroll' 'sms' 'nosmoothscroll' 'nosms'
'smoothscroll' 'sms'	boolean (default off)
local to window

Scrolling works with screen lines. When 'wrap' is set and the first line in the window wraps part of it may not be visible, as if it is above the window. "<<<" is displayed at the start of the first line, highlighted with hl-NonText.
You may also want to add "lastline" to the 'display' option to show as much of the last line as possible.
NOTE: partly implemented, doesn't work yet for gj and gk.

'softtabstop' 'sts'
'softtabstop' 'sts'	number (default 0)
local to buffer

Create soft tab stops, separated by 'softtabstop' number of columns.
In Insert mode, pressing the <Tab> key will move the cursor to the next soft tab stop, instead of inserting a literal tab. <BS> behaves similarly in reverse. Vim inserts a minimal mix of tab and space characters to produce the visual effect.

This setting does not affect the display of existing tab characters.

A value of 0 disables this behaviour. A negative value makes Vim use 'shiftwidth'. If you plan to use 'sts' and 'shiftwidth' with different values, you might consider setting 'smarttab'.

The 'L' flag in 'cpoptions' alters tab behavior when 'list' is enabled. See also ins-expandtab and user manual section 30.5 for in-depth explanations.

The value of 'softtabstop' will be ignored if 'varsofttabstop' is set to anything other than an empty string.

'spell' 'nospell'
'spell'	boolean (default off)
local to window

When on spell checking will be done. See spell.
The languages are specified with 'spelllang'.

'spellcapcheck' 'spc'
'spellcapcheck' 'spc'	string (default "[.?!]_[\])'"\t]\+")
local to buffer

Pattern to locate the end of a sentence. The following word will be checked to start with a capital letter. If not then it is highlighted with SpellCap hl-SpellCap (unless the word is also badly spelled).
When this check is not wanted make this option empty.
Only used when 'spell' is set.
Be careful with special characters, see option-backslash about including spaces and backslashes.

To set this option automatically depending on the language, see
set-spc-auto.

'spellfile' 'spf'

'spellfile' 'spf'	string (default "")
local to buffer
Disallowed in modeline. no-modeline-option
Name of the word list file where words are added for the zg and zw
commands. It must end in ".{encoding}.add". You need to include the
path, otherwise the file is placed in the current directory.
The path may include characters from 'isfname', ' ', ',', '@' and ':'.

E765

It may also be a comma-separated list of names. A count before the
zg and zw commands can be used to access each. This allows using
a personal word list file and a project word list file.
When a word is added while this option is empty Nvim will use
(and auto-create) stdpath('data')/site/spell/. For the file name the
first language name that appears in 'spelllang' is used, ignoring the
region.
The resulting ".spl" file will be used for spell checking, it does not
have to appear in 'spelllang'.
Normally one file is used for all regions, but you can add the region
name if you want to. However, it will then only be used when
'spellfile' is set to it, for entries in 'spelllang' only files
without region name will be found.
Environment variables are expanded :set_env.

'spelllang' 'spl'

'spelllang' 'spl'	string (default "en")
local to buffer
A comma-separated list of word list names. When the 'spell' option is
on spellchecking will be done for these languages. Example:

```
set spelllang=en_us,nl,medical
```

This means US English, Dutch and medical words are recognized. Words
that are not recognized will be highlighted.
The word list name must consist of alphanumeric characters, a dash or
an underscore. It should not include a comma or dot. Using a dash is
recommended to separate the two letter language name from a
specification. Thus "en-rare" is used for rare English words.
A region name must come last and have the form "_xx", where "xx" is
the two-letter, lower case region name. You can use more than one
region by listing them: "en_us,en_ca" supports both US and Canadian
English, but not words specific for Australia, New Zealand or Great
Britain. (**Note:** currently en_au and en_nz dictionaries are older than
en_ca, en_gb and en_us).
If the name "cjk" is included East Asian characters are excluded from
spell checking. This is useful when editing text that also has Asian
words.
Note that the "medical" dictionary does not exist, it is just an
example of a longer name.

E757

As a special case the name of a .spl file can be given as-is. The
first "_xx" in the name is removed and used as the region name
(_xx is an underscore, two letters and followed by a non-letter).
This is mainly for testing purposes. You must make sure the correct
encoding is used, Vim doesn't check it.
How the related spell files are found is explained here: spell-load.

If the package-spellfile plugin is active and you use a language name
for which Vim cannot find the .spl file in 'runtimepath' the plugin
will ask you if you want to download the file.

After this option has been set successfully, Vim will source the files
"spell/LANG.vim" in 'runtimepath'. "LANG" is the value of 'spelllang'
up to the first character that is not an ASCII letter or number and
not a dash. Also see set-spc-auto.

'spelloptions' 'spo'

'spelloptions' 'spo'	string (default "")
local to buffer
Disallowed in modeline. no-modeline-option
A comma-separated list of options for spell checking:
camel	When a word is CamelCased, assume "Cased" is a
separate word: every upper-case character in a word
that comes after a lower case character indicates the
start of a new word.
noplainbuffer	Only spellcheck a buffer when 'syntax' is enabled,
or when extmarks are set within the buffer. Only
designated regions of the buffer are spellchecked in
this case.

'spellsuggest' 'sps' E5700

'spellsuggest' 'sps'	string (default "best")
global
Disallowed in modeline. no-modeline-option
Methods used for spelling suggestions. Both for the z= command and
the spellsuggest() function. This is a comma-separated list of
items:

best Internal method that works best for English. Finds changes like "fast" and uses a bit of sound-a-like scoring to improve the ordering.

double Internal method that uses two methods and mixes the results. The first method is "fast", the other method computes how much the suggestion sounds like the bad word. That only works when the language specifies sound folding. Can be slow and doesn't always give better results.

fast Internal method that only checks for simple changes: character inserts/deletes/swaps. Works well for simple typing mistakes.

{number} The maximum number of suggestions listed for z=. Not used for spellsuggest(). The number of suggestions is never more than the value of 'lines' minus two.

timeout:{millisec} Limit the time searching for suggestions to {millisec} milliseconds. Applies to the following methods. When omitted the limit is 5000. When negative there is no limit.

file:{filename} Read file {filename}, which must have two columns, separated by a slash. The first column contains the bad word, the second column the suggested good word. Example:

```
theribal/terrible
```

Use this for common mistakes that do not appear at the top of the suggestion list with the internal methods. Lines without a slash are ignored, use this for comments.
The word in the second column must be correct, otherwise it will not be used. Add the word to an ".add" file if it is currently flagged as a spelling mistake.
The file is used for all languages.

expr:{expr} Evaluate expression {expr}. Use a function to avoid trouble with spaces. Best is to call a function without arguments, see expr-option-function. v:val holds the badly spelled word. The expression must evaluate to a List of Lists, each with a suggestion and a score.
Example:

```
[['the', 33], ['that', 44]]
```

Set 'verbose' and use z= to see the scores that the internal methods use. A lower score is better.
This may invoke spellsuggest() if you temporarily set 'spellsuggest' to exclude the "expr:" part. Errors are silently ignored, unless you set the 'verbose' option to a non-zero value.

Only one of "best", "double" or "fast" may be used. The others may appear several times in any order. Example:

```
set sps=file:~/.config/nvim/sugg,best,expr:MySuggest()
```

Environment variables are expanded :set_env.

'splitbelow' 'sb' 'nosplitbelow' 'nosb'
'splitbelow' 'sb' boolean (default off)
global
When on, splitting a window will put the new window below the current one. :split

'splitkeep' 'spk'
'splitkeep' 'spk' string (default "cursor")
global
The value of this option determines the scroll behavior when opening, closing or resizing horizontal splits.

Possible values are:
cursor Keep the same relative cursor position.
screen Keep the text on the same screen line.
topline Keep the topline the same.

For the "screen" and "topline" values, the cursor position will be changed when necessary. In this case, the jumplist will be populated with the previous cursor position. For "screen", the text cannot always be kept on the same screen line when 'wrap' is enabled.

'splitright' 'spr' 'nosplitright' 'nospr'
'splitright' 'spr' boolean (default off)
global
When on, splitting a window will put the new window right of the current one. :vsplit

'startofline' 'sol' 'nostartofline' 'nosol'
'startofline' 'sol' boolean (default off)
global
When "on" the commands listed below move the cursor to the first non-blank of the line. When off the cursor is kept in the same column (if possible). This applies to the commands:

- CTRL-D, CTRL-U, CTRL-B, CTRL-F, "G", "H", "M", "L", "gg"

- "d", "<<", "==" and ">>" with a linewise operator

  (operator-resulting-pos)
- "%" with a count

- buffer changing commands (CTRL-^, :bnext, :bNext, etc.)

- Ex commands that only have a line number, e.g., ":25" or ":+".

In case of buffer changing commands the cursor is placed at the column where it was the last time the buffer was edited.

'statuscolumn' 'stc'
'statuscolumn' 'stc'	string (default "")
local to window
Disallowed in modeline. no-modeline-option

When non-empty, this option determines the content of the area to the side of a window, normally containing the fold, sign and number columns. The format of this option is like that of 'statusline'.

Some of the items from the 'statusline' format are different for 'statuscolumn':

```
%l      line number column for currently drawn line
%s      sign column for currently drawn line
%C      fold column for currently drawn line
```

The 'statuscolumn' width follows that of the default columns and adapts to the 'numberwidth', 'signcolumn' and 'foldcolumn' option values (regardless of whether the sign and fold items are present). Additionally, the 'statuscolumn' grows with the size of the evaluated format string, up to a point (following the maximum size of the default fold, sign and number columns). Shrinking only happens when the number of lines in a buffer changes, or the 'statuscolumn' option is set.

```
The v:lnum    variable holds the line number to be drawn.
The v:relnum  variable holds the relative line number to be drawn.
The v:virtnum variable is negative when drawing virtual lines, zero
              when drawing the actual buffer line, and positive when
              drawing the wrapped part of a buffer line.
```

When using v:relnum, keep in mind that cursor movement by itself will not cause the 'statuscolumn' to update unless 'relativenumber' is set.

Examples:

```
" Line number with bar separator and click handlers:
set statuscolumn=%@SignCb@%s%=%T%@NumCb@%l│%T

" Line numbers in hexadecimal for non wrapped part of lines:
let &stc='%=%{v:virtnum>0?"":printf("%x",v:lnum)} '

" Human readable line numbers with thousands separator:
let &stc='%{substitute(v:lnum,"\\d\\zs\\ze\\'
          . '%(\\d\\d\\d\\)\\+$",",","g")}'

" Both relative and absolute line numbers with different
" highlighting for odd and even relative numbers:
let &stc='%#NonText#%{&nu?v:lnum:""}' .
 '%=%{&rnu&&(v:lnum%2)?"\ ".v:relnum:""}' .
 '%#LineNr#%{&rnu&&!(v:lnum%2)?"\ ".v:relnum:""}'
```

WARNING: this expression is evaluated for each screen line so defining an expensive expression can negatively affect render performance.

'statusline' 'stl' E540 E542
'statusline' 'stl'	string (default is very long)
global or local to window global-local

Sets the status-line.

Contains printf-style "%" items interspersed with normal text, where each item has the form:

```
%-0{minwid}.{maxwid}{item}
```

All fields except {item} are optional. Use "%%" to show a literal "%" char. Setting to empty (:set statusline=) sets the global value to the default.

stl-%!

When the option starts with "%!" then it is used as an expression, evaluated and the result is used as the option value. Example:

```
set statusline=%!MyStatusLine()
```

The g:statusline_winid variable will be set to the window-ID of the window that the status line belongs to.

The result can contain %{} items that will be evaluated too.
Note that the "%!" expression is evaluated in the context of the
current window and buffer, while %{} items are evaluated in the
context of the window that the statusline belongs to.

When there is an error while evaluating the option it will be reset to
its default value to avoid further errors. Otherwise screen updating
would loop. When the result contains unprintable characters the
result is unpredictable.

When 'ruler' is on, the default 'statusline' includes 'rulerformat'.
See note below.
Note that if 'statusline' is configured without including the ruler,
the only effect of 'ruler' when this option is set (and 'laststatus'
is 2 or 3) is controlling the output of CTRL-G.

field	meaning
-	Left justify the item. The default is right justified when minwid is larger than the length of the item.
0	Leading zeroes in numeric items. Overridden by "-".
minwid	Minimum width of the item, padding as set by "-" & "0". Value must be 50 or less.
maxwid	Maximum width of the item. Truncation occurs with a "<" on the left for text items. Numeric items will be shifted down to maxwid-2 digits followed by ">"number where number is the amount of missing digits, much like an exponential notation.
item	A one letter code as described below.

Following is a description of the possible statusline items. The
second character in "item" is the type:
        "N" for number
        "S" for string
        "F" for flags as described below
        "-" not applicable

item meaning
f S   Path to the file in the buffer, as typed or relative to current
      directory.
F S   Full path to the file in the buffer.
t S   File name (tail) of file in the buffer.
m F   Modified flag, text is "[+]"; "[-]" if 'modifiable' is off.
M F   Modified flag, text is ",+" or ",-".
r F   Readonly flag, text is "[RO]".
R F   Readonly flag, text is ",RO".
h F   Help buffer flag, text is "[help]".
H F   Help buffer flag, text is ",HLP".
w F   Preview window flag, text is "[Preview]".
W F   Preview window flag, text is ",PRV".
y F   Type of file in the buffer, e.g., "[vim]". See 'filetype'.
Y F   Type of file in the buffer, e.g., ",VIM". See 'filetype'.
q S   "[Quickfix List]", "[Location List]" or empty.
k S   Value of "b:keymap_name" or 'keymap' when :lmap mappings are
      being used: "<keymap>"
n N   Buffer number.
b N   Value of character under cursor.
B N   As above, in hexadecimal.
o N   Byte number in file of byte under cursor, first byte is 1.
      Mnemonic: Offset from start of file (with one added)
O N   As above, in hexadecimal.
l N   Line number.
L N   Number of lines in buffer.
c N   Column number (byte index).
v N   Virtual column number (screen column).
V N   Virtual column number as -{num}. Not displayed if equal to 'c'.
p N   Percentage through file in lines as in CTRL-G.
P S   Percentage through file of displayed window. This is like the
      percentage described for 'ruler'. Always 3 in length, unless
      translated.
S S   'showcmd' content, see 'showcmdloc'.
a S   Argument list status as in default title. ({current} of {max})
      Empty if the argument file count is zero or one.
{ NF Evaluate expression between "%{" and "}" and substitute result.
      Note that there is no "%" before the closing "}". The
      expression cannot contain a "}" character, call a function to
      work around that. See stl-%{ below. Use "%0{" to insert the
      result verbatim.
{% - This is almost same as "{" except the result of the expression is
      re-evaluated as a statusline format string. Thus if the
      return value of expr contains "%" items they will get expanded.
      The expression can contain the "}" character, the end of
      expression is denoted by "%}".
      For example:

```
func! Stl_filename() abort
    return "%t"
endfunc
```

        stl=%{Stl_filename()}   results in "%t"
        stl=%{%Stl_filename()%} results in "Name of current file"
      The default status line uses this to include 'rulerformat', see

note below.
%} - End of "{%" expression
(- Start of item group. Can be used for setting the width and alignment of a section. Must be followed by %) somewhere.
) - End of item group. No width fields allowed.
T N For 'tabline': start of tabpage N label. Use %T or %X to end the label. Clicking this label with left mouse button switches to the specified tabpage, while clicking it with middle mouse button closes the specified tabpage.
X N For 'tabline': start of close tab N label. Use %X or %T to end the label, e.g.: %3Xclose%X. Use %999X for a "close current tab" label. Clicking this label with left mouse button closes the specified tabpage.
@ N Start of execute function label. Use %X or %T to end the label, e.g.: %10@SwitchBuffer@foo.c%X. Clicking this label runs the specified function: in the example when clicking once using left mouse button on "foo.c", a SwitchBuffer(10, 1, 'l', ' ') expression will be run. The specified function receives the following arguments in order:

1. minwid field value or zero if no N was specified

2. number of mouse clicks to detect multiple clicks

3. mouse button used: "l", "r" or "m" for left, right or middle

button respectively; one should not rely on third argument being only "l", "r" or "m": any other non-empty string value that contains only ASCII lower case letters may be expected for other mouse buttons

4. modifiers pressed: string which contains "s" if shift

modifier was pressed, "c" for control, "a" for alt and "m" for meta; currently if modifier is not pressed string contains space instead, but one should not rely on presence of spaces or specific order of modifiers: use stridx() to test whether some modifier is present; string is guaranteed to contain only ASCII letters and spaces, one letter per modifier; "?" modifier may also be present, but its presence is a bug that denotes that new mouse button recognition was added without modifying code that reacts on mouse clicks on this label.

Use getmousepos().winid in the specified function to get the corresponding window-ID of the clicked item.
< - Where to truncate line if too long. Default is at the first item. Truncation markers within item groups apply to the truncation of that group until its maxwid is reached. In case of several competing truncation markers, the first wins. No width fields allowed.
= - Separation point between alignment sections. Each section will be separated by an equal number of spaces. With one %= what comes after it will be right-aligned. With two %= there is a middle part, with white space left and right of it. Alignment sections within item groups will be separated until minwid of the group is reached. No width fields allowed.
- Set highlight group. The name must follow and then a # again. Thus use %#HLname# for highlight group HLname. The same highlighting is used, also for the statusline of non-current windows.
$ - Same as #, except the %$HLname$ group will inherit from preceding highlight attributes.
* - Set highlight group to User{N}, where {N} is taken from the minwid field, e.g. %1*. Restore normal highlight with %* or %0*. The difference between User{N} and StatusLine will be applied to StatusLineNC for the statusline of non-current windows. The number N must be between 1 and 9. See hl-User1..9
#(- Start of a highlight scope. The exact highlighting before the scope is reset at the end. No width fields allowed.
#) - End of highlight scope. No width fields allowed.

When displaying a flag, Vim removes the leading comma, if any, when that flag comes right after plaintext. This will make a nice display when flags are used like in the examples below.

When all items in a group becomes an empty string (i.e. flags that are not set) and a minwid is not set for the group, the whole group will become empty. This will make a group like the following disappear completely from the statusline when none of the flags are set.

```
set statusline=...%(\ [%M%R%H]%)...
```

Beware that an expression is evaluated each and every time the status line is displayed.
stl-%{ g:actual_curbuf g:actual_curwin
While evaluating %{} the current buffer and current window will be set

temporarily to that of the window (and buffer) whose statusline is currently being drawn. The expression will evaluate in this context. The variable "g:actual_curbuf" is set to the bufnr() number of the real current buffer and "g:actual_curwin" to the window-ID of the real current window. These values are strings.

The 'statusline' option will be evaluated in the sandbox if set from a modeline, see sandbox-option.
This option cannot be set in a modeline when 'modelineexpr' is off.

It is not allowed to change text or jump to another window while evaluating 'statusline' textlock.

If the statusline is not updated when you want it (e.g., after setting a variable that's used in an expression), you can force an update by using :redrawstatus.

A result of all digits is regarded a number for display purposes. Otherwise the result is taken as flag text and applied to the rules described above.

stl-%0{

With %0{ neither applies: the result is inserted as a literal string.

Watch out for errors in expressions. They may render Vim unusable! If you are stuck, hold down ':' or 'Q' to get a prompt, then quit and edit your vimrc or whatever with "vim --clean" to get it right.

Examples:
A simple version of the standard status line with 'ruler' set

```
set statusline=%f\ %h%w%m%r%=\ %-14.(%l,%c%V%)\ %P
```

Similar, but add ASCII value of char under the cursor (like "ga")

```
set statusline=%f%h%m%r%=\ %b\ 0x%B\ \ %l,%c%V\ %P
```

Display byte count and byte value, modified flag in red.

```
set statusline=%f%=\ [%1*%M%*%n%R%H]\ %-19(%3l,%02c%03V%)%O'%02b'
hi User1 term=inverse,bold cterm=inverse,bold ctermfg=red
```

Display a ,GZ flag if a compressed file is loaded

```
set statusline=...%r%{VarExists('b:gzflag','\ [GZ]')}%h...
```

In the :autocmd's:

```
let b:gzflag = 1
```

And:

```
unlet b:gzflag
```

And define this function:

```
function VarExists(var, val)
    if exists(a:var) | return a:val | else | return '' | endif
endfunction
```

Note: By default, the status line is truncated from the left, and the ruler from the right. But the status line can include the ruler. To ensure that a top-level (i.e. not inside an item group) %< in 'rulerformat' doesn't change the truncation of the status line,

- 'statusline' can be prepended with an explicit %<, which otherwise

  would not be necessary. Example:

  ```
  set statusline=%<%f%=\ %{%&rulerformat%}
  ```

- Or the ruler can be wrapped in an item group, which also collapses

  any top-level %= in 'rulerformat' unless minwid is specified:

  ```
  set statusline=%f%=\ %(%{%&rulerformat%}%)
  ```

'suffixes' 'su'

'suffixes' 'su' string (default ".bak,~,.o,.h,.info,.swp,.obj")
global
Files with these suffixes get a lower priority when multiple files match a wildcard. See suffixes. Commas can be used to separate the suffixes. Spaces after the comma are ignored. A dot is also seen as the start of a suffix. To avoid a dot or comma being recognized as a separator, precede it with a backslash (see option-backslash about including spaces and backslashes).
See 'wildignore' for completely ignoring files.
The use of :set+= and :set-= is preferred when adding or removing suffixes from the list. This avoids problems when a future version uses another default.

'suffixesadd' 'sua'

'suffixesadd' 'sua'	string (default "")
		local to buffer
	Comma-separated list of suffixes, which are used when searching for a
	file for the "gf", "[I", etc. commands. Example:

```
set suffixesadd=.java
```

'swapfile' 'swf' 'noswapfile' 'noswf'

'swapfile' 'swf'	boolean (default on)
		local to buffer
	Use a swap-file for the buffer (if 'updatecount' is non-zero). The
	'directory' option decides where swapfiles are stored.

	To open a new buffer without creating a swapfile, use :noswapfile.
	To disable for an existing buffer, reset its 'swapfile' option.
	Careful:

- Recovery will be impossible!

- The entire file will be in memory.

	When reset, the swapfile for the current buffer is immediately
	deleted. When re-enabled (and 'updatecount' is non-zero), a swapfile
	is immediately created.

	Used with 'bufhidden' and 'buftype' to specify special-buffers.

'switchbuf' 'swb'

'switchbuf' 'swb'	string (default "uselast")
		global
	This option controls the behavior when switching between buffers.
	This option is checked, when

- jumping to errors with the quickfix commands (:cc, :cn, :cp,

	  etc.).

- jumping to a tag using the :stag command.

- opening a file using the CTRL-W_f or CTRL-W_F command.

- jumping to a buffer using a buffer split command (e.g. :sbuffer,

	  :sbnext, or :sbrewind).
	Possible values (comma-separated list):
	   useopen	If included, jump to the first open window in the
			current tabpage that contains the specified buffer
			(if there is one). Otherwise: Do not examine other
			windows.
	   usetab	Like "useopen", but also consider windows in other
			tabpages.
	   split	If included, split the current window before loading
			a buffer for a quickfix command that display errors.
			Otherwise: do not split, use current window (when used
			in the quickfix window: the previously used window or
			split if there is no other window).
	   vsplit	Just like "split" but split vertically.
	   newtab	Like "split", but open a new tabpage. Overrules
			"split" when both are present.
	   uselast	If included, jump to the previously used window when
			jumping to errors with quickfix commands.
	If a window has 'winfixbuf' enabled, 'switchbuf' is currently not
	applied to the split window.

'synmaxcol' 'smc'

'synmaxcol' 'smc'	number (default 3000)
		local to buffer
	Maximum column in which to search for syntax items. In long lines the
	text after this column is not highlighted and following lines may not
	be highlighted correctly, because the syntax state is cleared.
	This helps to avoid very slow redrawing for an XML file that is one
	long line.
	Set to zero to remove the limit.

'syntax' 'syn'

'syntax' 'syn'	string (default "")
		local to buffer local-noglobal
	When this option is set, the syntax with this name is loaded, unless
	syntax highlighting has been switched off with ":syntax off".
	Otherwise this option does not always reflect the current syntax (the
	b:current_syntax variable does).
	This option is most useful in a modeline, for a file which syntax is
	not automatically recognized. Example, in an IDL file:

```
/* vim: set syntax=idl : */
```

	When a dot appears in the value then this separates two filetype
	names. Example:

```
/* vim: set syntax=c.doxygen : */
```

This will use the "c" syntax first, then the "doxygen" syntax.
Note that the second one must be prepared to be loaded as an addition,
otherwise it will be skipped. More than one dot may appear.
To switch off syntax highlighting for the current file, use:

```
set syntax=OFF
```

To switch syntax highlighting on according to the current value of the
'filetype' option:

```
set syntax=ON
```

What actually happens when setting the 'syntax' option is that the
Syntax autocommand event is triggered with the value as argument.
This option is not copied to another buffer, independent of the 's' or
'S' flag in 'cpoptions'.
Only alphanumeric characters, '.', '-' and '_' can be used.

'tabclose' 'tcl'
'tabclose' 'tcl'	string (default "")
global
This option controls the behavior when closing tabpages (e.g., using
:tabclose). When empty Vim goes to the next (right) tabpage.

Possible values (comma-separated list):
left	If included, go to the previous tabpage instead of
the next one.
uselast	If included, go to the previously used tabpage if
possible. This option takes precedence over the
others.

'tabline' 'tal'
'tabline' 'tal'	string (default "")
global
When non-empty, this option determines the content of the tabpages
line at the top of the Vim window. When empty Vim will use a default
tabpages line. See setting-tabline for more info.

The tabpages line only appears as specified with the 'showtabline'
option and only when there is no GUI tab line. When 'e' is in
'guioptions' and the GUI supports a tab line 'guitablabel' is used
instead. Note that the two tabpages lines are very different.

The value is evaluated like with 'statusline'. You can use
tabpagenr(), tabpagewinnr() and tabpagebuflist() to figure out
the text to be displayed. Use "%1T" for the first label, "%2T" for
the second one, etc. Use "%X" items for closing labels.

When changing something that is used in 'tabline' that does not
trigger it to be updated, use :redrawtabline.
This option cannot be set in a modeline when 'modelineexpr' is off.

Keep in mind that only one of the tabpages is the current one, others
are invisible and you can't jump to their windows.

'tabpagemax' 'tpm'
'tabpagemax' 'tpm'	number (default 50)
global
Maximum number of tabpages to be opened by the -p command line
argument or the ":tab all" command. tabpage

'tabstop' 'ts'
'tabstop' 'ts'	number (default 8)
local to buffer
Defines the column multiple used to display the Horizontal Tab
character (ASCII 9); a Horizontal Tab always advances to the next tab
stop.
The value must be at least 1 and at most 9999.
If 'vartabstop' is set, this option is ignored.
Leave it at 8 unless you have a strong reason (see usr 30.5).

'tagbsearch' 'tbs' 'notagbsearch' 'notbs'
'tagbsearch' 'tbs'	boolean (default on)
global
When searching for a tag (e.g., for the :ta command), Vim can either
use a binary search or a linear search in a tags file. Binary
searching makes searching for a tag a LOT faster, but a linear search
will find more tags if the tags file wasn't properly sorted.
Vim normally assumes that your tags files are sorted, or indicate that
they are not sorted. Only when this is not the case does the
'tagbsearch' option need to be switched off.

When 'tagbsearch' is on, binary searching is first used in the tags
files. In certain situations, Vim will do a linear search instead for
certain files, or retry all files with a linear search. When
'tagbsearch' is off, only a linear search is done.

Linear searching is done anyway, for one file, when Vim finds a line
at the start of the file indicating that it's not sorted:

```
!_TAG_FILE_SORTED	0	/some comment/
```

[The whitespace before and after the '0' must be a single <Tab>]

When a binary search was done and no match was found in any of the files listed in 'tags', and case is ignored or a pattern is used instead of a normal tag name, a retry is done with a linear search. Tags in unsorted tags files, and matches with different case will only be found in the retry.

If a tag file indicates that it is case-fold sorted, the second, linear search can be avoided when case is ignored. Use a value of '2' in the "!_TAG_FILE_SORTED" line for this. A tag file can be case-fold sorted with the -f switch to "sort" in most unices, as in the command: "sort -f -o tags tags". For Universal ctags and Exuberant ctags version 5.x or higher (at least 5.5) the --sort=foldcase switch can be used for this as well. Note that case must be folded to uppercase for this to work.

By default, tag searches are case-sensitive. Case is ignored when 'ignorecase' is set and 'tagcase' is "followic", or when 'tagcase' is "ignore".
Also when 'tagcase' is "followscs" and 'smartcase' is set, or 'tagcase' is "smart", and the pattern contains only lowercase characters.

When 'tagbsearch' is off, tags searching is slower when a full match exists, but faster when no full match exists. Tags in unsorted tags files may only be found with 'tagbsearch' off.
When the tags file is not sorted, or sorted in a wrong way (not on ASCII byte value), 'tagbsearch' should be off, or the line given above must be included in the tags file.
This option doesn't affect commands that find all matching tags (e.g., command-line completion and ":help").

'tagcase' 'tc'

'tagcase' 'tc' string (default "followic")
global or local to buffer global-local

This option specifies how case is handled when searching the tags file:

followic	Follow the 'ignorecase' option
followscs	Follow the 'smartcase' and 'ignorecase' options
ignore	Ignore case
match	Match case
smart	Ignore case unless an upper case letter is used

'tagfunc' 'tfu'

'tagfunc' 'tfu' string (default "")
local to buffer
Disallowed in modeline. no-modeline-option

This option specifies a function to be used to perform tag searches (including taglist()).
The function gets the tag pattern and should return a List of matching tags. See tag-function for an explanation of how to write the function and an example. The value can be the name of a function, a lambda or a Funcref. See option-value-function for more information.

'taglength' 'tl'

'taglength' 'tl' number (default 0)
global

If non-zero, tags are significant up to this number of characters.

'tagrelative' 'tr' 'notagrelative' 'notr'

'tagrelative' 'tr' boolean (default on)
global

If on and using a tags file in another directory, file names in that tags file are relative to the directory where the tags file is.

'tags' 'tag' E433

'tags' 'tag' string (default "./tags;,tags")
global or local to buffer global-local

Filenames for the tag command, separated by spaces or commas. To include a space or comma in a file name, precede it with backslashes (see option-backslash about including spaces/commas and backslashes). When a file name starts with "./", the '.' is replaced with the path of the current file. But only when the 'd' flag is not included in 'cpoptions'. Environment variables are expanded :set_env. Also see tags-option.
"*", "**" and other wildcards can be used to search for tags files in a directory tree. See file-searching. E.g., "/lib/**/tags" will find all files named "tags" below "/lib". The filename itself cannot contain wildcards, it is used as-is. E.g., "/lib/**/tags?" will find files called "tags?".
The tagfiles() function can be used to get a list of the file names actually used.
The use of :set+= and :set-= is preferred when adding or removing file names from the list. This avoids problems when a future version uses another default.

'tagstack' 'tgst' 'notagstack' 'notgst'

'tagstack' 'tgst' boolean (default on)
global

When on, the tagstack is used normally. When off, a ":tag" or ":tselect" command with an argument will not push the tag onto the tagstack. A following ":tag" without an argument, a ":pop" command or any other command that uses the tagstack will use the unmodified tagstack, but does change the pointer to the active entry.

Resetting this option is useful when using a ":tag" command in a
mapping which should not change the tagstack.

'termbidi' 'tbidi' 'notermbidi' 'notbidi'
'termbidi' 'tbidi' boolean (default off)
global
The terminal is in charge of Bi-directionality of text (as specified
by Unicode). The terminal is also expected to do the required shaping
that some languages (such as Arabic) require.
Setting this option implies that 'rightleft' will not be set when
'arabic' is set and the value of 'arabicshape' will be ignored.
Note that setting 'termbidi' has the immediate effect that
'arabicshape' is ignored, but 'rightleft' isn't changed automatically.
For further details see l10n-arabic.txt.

'termguicolors' 'tgc' 'notermguicolors' 'notgc'
'termguicolors' 'tgc' boolean (default off)
global
Enables 24-bit RGB color in the TUI. Uses "gui" :highlight
attributes instead of "cterm" attributes. guifg
Requires an ISO-8613-3 compatible terminal.

Nvim will automatically attempt to determine if the host terminal
supports 24-bit color and will enable this option if it does
(unless explicitly disabled by the user).

'termpastefilter' 'tpf'
'termpastefilter' 'tpf' string (default "BS,HT,ESC,DEL")
global
A comma-separated list of options for specifying control characters
to be removed from the text pasted into the terminal window. The
supported values are:

BS Backspace

HT TAB

FF Form feed

ESC Escape

DEL DEL

C0 Other control characters, excluding Line feed and
Carriage return < ' '

C1 Control characters 0x80...0x9F

'termsync' 'notermsync'
'termsync' boolean (default on)
global
If the host terminal supports it, buffer all screen updates
made during a redraw cycle so that each screen is displayed in
the terminal all at once. This can prevent tearing or flickering
when the terminal updates faster than Nvim can redraw.

'textwidth' 'tw'
'textwidth' 'tw' number (default 0)
local to buffer
Maximum width of text that is being inserted. A longer line will be
broken after white space to get this width. A zero value disables
this.
When 'textwidth' is zero, 'wrapmargin' may be used. See also
'formatoptions' and ins-textwidth.
When 'formatexpr' is set it will be used to break the line.

'thesaurus' 'tsr'
'thesaurus' 'tsr' string (default "")
global or local to buffer global-local
List of file names, separated by commas, that are used to lookup words
for thesaurus completion commands i_CTRL-X_CTRL-T. See
compl-thesaurus.

This option is not used if 'thesaurusfunc' is set, either for the
buffer or globally.

To include a comma in a file name precede it with a backslash. Spaces
after a comma are ignored, otherwise spaces are included in the file
name. See option-backslash about using backslashes. The use of
:set+= and :set-= is preferred when adding or removing directories
from the list. This avoids problems when a future version uses
another default.
Environment variables are expanded :set_env.
Backticks cannot be used in this option for security reasons.

'thesaurusfunc' 'tsrfu'
'thesaurusfunc' 'tsrfu' string (default "")
global or local to buffer global-local
Disallowed in modeline. no-modeline-option
This option specifies a function to be used for thesaurus completion
with CTRL-X CTRL-T. i_CTRL-X_CTRL-T See compl-thesaurusfunc.
The value can be the name of a function, a lambda or a Funcref.
See option-value-function for more information.

'tildeop' 'top' 'notildeop' 'notop'
'tildeop' 'top' boolean (default off)
global
When on: The tilde command "~" behaves like an operator.

'timeout' 'to' 'notimeout' 'noto'
'timeout' 'to' boolean (default on)

global
This option and 'timeoutlen' determine the behavior when part of a mapped key sequence has been received. For example, if <c-f> is pressed and 'timeout' is set, Nvim will wait 'timeoutlen' milliseconds for any key that can follow <c-f> in a mapping.

'timeoutlen' 'tm'

'timeoutlen' 'tm' number (default 1000)
global
Time in milliseconds to wait for a mapped sequence to complete.

'title' 'notitle'

'title' boolean (default off)
global
If enabled, Nvim will update the (GUI or terminal) window title. The format is configured by 'titlestring'. By default it looks like:

```
filename [+=-] (path) - Nvim
```

where:

```
filename        the name of the file being edited
-               indicates the file cannot be modified, 'ma' off
+               indicates the file was modified
=               indicates the file is read-only
=+              indicates the file is read-only and modified
(path)          is the path of the file being edited
- Nvim          the server name |v:servername| or "Nvim"
```

'titlelen'

'titlelen' number (default 85)
global
Gives the percentage of 'columns' to use for the length of the window title. When the title is longer, only the end of the path name is shown. A '<' character before the path name is used to indicate this. Using a percentage makes this adapt to the width of the window. But it won't work perfectly, because the actual number of characters available also depends on the font used and other things in the title bar. When 'titlelen' is zero the full path is used. Otherwise, values from 1 to 30000 percent can be used.
'titlelen' is also used for the 'titlestring' option.

'titleold'

'titleold' string (default "")
global
Disallowed in modeline. no-modeline-option
If not empty, this option will be used to set the window title when exiting. Only if 'title' is enabled.

'titlestring'

'titlestring' string (default "")
global
Formats the window title, enabled by the 'title' option.

Contains printf-style "%" items, expanded according to the rules of 'statusline'. If a "%" format is invalid, it is used as-is and no error will be given.

The default (empty) behaviour is equivalent to:

```
set titlestring=%t%(\ %M%)%(\ \(%{expand('%:p:~:h')}\)%)%a\ -\ Nvim
```

Example:

```
auto BufEnter * let &titlestring = hostname() .. "/" .. expand("%:p")
set title titlestring=%<%F%=%l/%L-%P titlelen=70
```

The value of 'titlelen' is used to align items in the middle or right of the available space.

Example: to have the file name first:

```
set titlestring=%t%(\ %M%)%(\ (%{expand(\"%:~:.:h\")})%)%(\ %a%)
```

Note the use of "%{ }" and an expression to get the path of the file, without the file name. The "%(%)" constructs add a separating space only when needed.

NOTE: Use of special characters in 'titlestring' may cause the display to be garbled (e.g., when it contains a CR or NL character).

This option cannot be set in a modeline when 'modelineexpr' is off.

'ttimeout' 'nottimeout'

'ttimeout' boolean (default on)
global
This option and 'ttimeoutlen' determine the behavior when part of a key code sequence has been received by the TUI.

For example if <Esc> (the \x1b byte) is received and 'ttimeout' is set, Nvim waits 'ttimeoutlen' milliseconds for the terminal to complete a key code sequence. If no input arrives before the timeout, a single <Esc> is assumed. Many TUI cursor key codes start with <Esc>.

On very slow systems this may fail, causing cursor keys not to work
sometimes. If you discover this problem you can ":set ttimeoutlen=9999".
Nvim will wait for the next character to arrive after an <Esc>.

'ttimeoutlen' 'ttm'
'ttimeoutlen' 'ttm'	number (default 50)
global
Time in milliseconds to wait for a key code sequence to complete. Also
used for CTRL-\ CTRL-N and CTRL-\ CTRL-G when part of a command has
been typed.

'ttyfast' 'tf' 'nottyfast' 'notf' E1568 $NVIM_NOTTYFAST
'ttyfast' 'tf'	boolean (default on)
global
Enables Nvim TUI features which assume a fast (usually local) host
terminal. During startup, Nvim queries the terminal (for 'background'
detection, etc.) and must wait for a response (or timeout).

If your terminal environment is slow (e.g. remote SSH), or broken
(doesn't respond to queries), Nvim startup may be slower. Therefore
you can disable this option by setting the $NVIM_NOTTYFAST
environment variable before starting Nvim:

```
NVIM_NOTTYFAST=1 nvim
```

The queries are performed early, before --cmd and user config, so
:set nottyfast in your config happens too late.

'undodir' 'udir' E5003
'undodir' 'udir'	string (default "$XDG_STATE_HOME/nvim/undo//")
global
Disallowed in modeline. no-modeline-option
List of directory names for undo files, separated with commas.
See 'backupdir' for details of the format.
"." means using the directory of the file. The undo file name for
"file.txt" is ".file.txt.un~".
For other directories the file name is the full path of the edited
file, with path separators replaced with "%".
When writing: The first directory that exists is used. "." always
works, no directories after "." will be used for writing. If none of
the directories exist Nvim will attempt to create the last directory in
the list.
When reading all entries are tried to find an undo file. The first
undo file that exists is used. When it cannot be read an error is
given, no further entry is used.
See undo-persistence.
Environment variables are expanded :set_env.

Note that unlike 'directory' and 'backupdir', 'undodir' always acts as
though the trailing slashes are present (see 'backupdir' for what this
means).

'undofile' 'udf' 'noundofile' 'noudf'
'undofile' 'udf'	boolean (default off)
local to buffer
When on, Vim automatically saves undo history to an undo file when
writing a buffer to a file, and restores undo history from the same
file on buffer read.
The directory where the undo file is stored is specified by 'undodir'.
For more information about this feature see undo-persistence.
The undo file is not read when 'undoreload' causes the buffer from
before a reload to be saved for undo.
When 'undofile' is turned off the undo file is NOT deleted.

'undolevels' 'ul'
'undolevels' 'ul'	number (default 1000)
global or local to buffer global-local
Maximum number of changes that can be undone. Since undo information
is kept in memory, higher numbers will cause more memory to be used.
Nevertheless, a single change can already use a large amount of
memory. Set to 0 for Vi compatibility: One level of undo and "u"
undoes itself:

```
set ul=0
```

But you can also get Vi compatibility by including the 'u' flag in
'cpoptions', and still be able to use CTRL-R to repeat undo.
Also see undo-two-ways.
Set to -1 for no undo at all. You might want to do this only for the
current buffer:

```
setlocal ul=-1
```

This helps when you run out of memory for a single change.

The local value is set to -123456 when the global value is to be used.

Also see clear-undo.

'undoreload' 'ur'
'undoreload' 'ur'	number (default 10000)
global
Save the whole buffer for undo when reloading it. This applies to the
":e!" command and reloading for when the buffer changed outside of
Vim. FileChangedShell

The save only happens when this option is negative or when the number of lines is smaller than the value of this option.
Set this option to zero to disable undo for a reload.

When saving undo for a reload, any undo file is not read.

Note that this causes the whole buffer to be stored in memory. Set this option to a lower value if you run out of memory.

'updatecount' 'uc'
'updatecount' 'uc' number (default 200)
global
The swap-file will be written after typing this many characters.

- Ignored in buffers where 'buftype' is "nofile" or "nowrite".

- Initialized to 10000 when editing in readonly -R mode.

- To disable swapfiles per-buffer, unset the 'swapfile' option.

- To disable swapfiles globally, set this option to zero (or start

with -n). See crash-recovery. Existing swapfiles are not deleted.
- When re-enabled (from zero to non-zero), swapfiles are created for

all buffers that have 'swapfile' set.

'updatetime' 'ut'
'updatetime' 'ut' number (default 4000)
global
If this many milliseconds nothing is typed the swap file will be written to disk (see crash-recovery). Also used for the CursorHold autocommand event.

'varsofttabstop' 'vsts'
'varsofttabstop' 'vsts' string (default "")
local to buffer
Defines variable-width soft tab stops. The value is a comma-separated list of widths in columns. Each width defines the number of columns before the next soft tab stop. The last value repeats indefinitely.

For example, when editing assembly language files where statements start in the 9th column and comments in the 41st, it may be useful to use the following:

```
set varsofttabstop=8,32,8
```

This sets soft tab stops at column 8, then at column 40 (8 + 32), and every 8 columns thereafter.

Note: this setting overrides 'softtabstop'.
See section 30.5 of the user manual for detailed explanations on how Vim works with tabs and spaces.

'vartabstop' 'vts'
'vartabstop' 'vts' string (default "")
local to buffer
Defines variable-width tab stops. The value is a comma-separated list of widths in columns. Each width defines the number of columns before the next tab stop; the last value repeats indefinitely.

For example:

```
:set vartabstop=4,8
```

This places the first tab stop 4 columns from the start of the line and each subsequent tab stop 8 columns apart.

Note: this setting overrides 'tabstop'.
On UNIX, it is recommended to keep the default tabstop value of 8.
Consider setting 'varsofttabstop' instead.
See section 30.5 of the user manual for detailed explanations on how Vim works with tabs and spaces.

'verbose' 'vbs'
'verbose' 'vbs' number (default 0)
global
Sets the verbosity level. Also set by -V and :verbose.

Tracing of assignments to options, mappings, etc. in Lua scripts is enabled at level 1; Lua scripts are not traced when 'verbose' is 0, for performance.

If greater than or equal to a given level, Nvim produces the following messages:

Level	Messages
1	Enables Lua tracing (see above). Does not produce messages.
2	When a file is ":source"'ed, or shada file is read or written.
3	UI info, terminal capabilities.
4	Shell commands.
5	Every searched tags file and include file.

```
        8       Files for which a group of autocommands is executed.
        9       Executed autocommands.
        11      Finding items in a path.
        12      Vimscript function calls.
        13      When an exception is thrown, caught, finished, or discarded.
        14      Anything pending in a ":finally" clause.
        15      Ex commands from a script (truncated at 200 characters).
        16      Ex commands.
```

If 'verbosefile' is set then the verbose messages are not displayed.

'verbosefile' 'vfile'

'verbosefile' 'vfile' string (default "")
                       global
                       Disallowed in modeline. no-modeline-option
When not empty all messages are written in a file with this name.
When the file exists messages are appended.
Writing to the file ends when Vim exits or when 'verbosefile' is made
empty. Writes are buffered, thus may not show up for some time.
Setting 'verbosefile' to a new value is like making it empty first.
The difference with :redir is that verbose messages are not
displayed when 'verbosefile' is set.
Environment variables are expanded :set_env.

'viewdir' 'vdir'

'viewdir' 'vdir'   string (default "$XDG_STATE_HOME/nvim/view//")
                       global
                       Disallowed in modeline. no-modeline-option
Name of the directory where to store files for :mkview.
Environment variables are expanded :set_env.

'viewoptions' 'vop'

'viewoptions' 'vop'   string (default "folds,cursor,curdir")
                       global
Changes the effect of the :mkview command. It is a comma-separated
list of words. Each word enables saving and restoring something:
word   **save and restore**
   cursor   cursor position in file and in window
   curdir   local current directory, if set with :lcd
   folds   manually created folds, opened/closed folds and local
               fold options
   options   options and mappings local to a window or buffer (not
               global values for local options), except Lua functions
               option-value-function.
   localoptions same as "options"
   slash   deprecated Always enabled. Uses "/" in filenames.
   unix   deprecated Always enabled. Uses "\n" line endings.

'virtualedit' 've'

'virtualedit' 've'   string (default "")
                       global or local to window global-local
A comma-separated list of these words:
    block   Allow virtual editing in Visual block mode.
    insert   Allow virtual editing in Insert mode.
    all   Allow virtual editing in all modes.
    onemore   Allow the cursor to move just past the end of the line
    none   When used as the local value, do not allow virtual
               editing even when the global value is set. When used
               as the global value, "none" is the same as "".
    NONE   Alternative spelling of "none".

Virtual editing means that the cursor can be positioned where there is
no actual character. This can be halfway into a tab or beyond the end
of the line. Useful for selecting a rectangle in Visual mode and
editing a table.
"onemore" is not the same, it will only allow moving the cursor just
after the last character of the line. This makes some commands more
consistent. Previously the cursor was always past the end of the line
if the line was empty. But it is far from Vi compatible. It may also
break some plugins or Vim scripts. For example because l can move
the cursor after the last character. Use with care!
Using the $ command will move to the last character in the line, not
past it. This may actually move the cursor to the left!
The g$ command will move to the end of the screen line.
It doesn't make sense to combine "all" with "onemore", but you will
not get a warning for it.
When combined with other words, "none" is ignored.

'visualbell' 'vb' 'novisualbell' 'novb'

'visualbell' 'vb'   boolean (default off)
                       global
Use visual bell instead of beeping. Also see 'errorbells'.

'warn' 'nowarn'

'warn'   boolean (default on)
                       global
Give a warning message when a shell command is used while the buffer
has been changed.

'whichwrap' 'ww'

'whichwrap' 'ww'   string (default "b,s")
                       global
Allow specified keys that move the cursor left/right to move to the
previous/next line when the cursor is on the first/last character in
the line. Concatenate characters to allow this for these keys:
```
```

```
char   key        mode
                b    <BS>       Normal and Visual
                s    <Space>    Normal and Visual
                h    "h"        Normal and Visual (not recommended)
                l    "l"        Normal and Visual (not recommended)
                <    <Left>     Normal and Visual
                >    <Right>    Normal and Visual
                ~    "~"        Normal
                [    <Left>     Insert and Replace
                ]    <Right>    Insert and Replace
        For example:
```

```
set ww=<,>,[,]
```

```
        allows wrap only when cursor keys are used.
        When the movement keys are used in combination with a delete or change
        operator, the <EOL> also counts for a character.  This makes "3h"
        different from "3dh" when the cursor crosses the end of a line.  This
        is also true for "x" and "X", because they do the same as "dl" and
        "dh".  If you use this, you may also want to use the mapping
        ":map <BS> X" to make backspace delete the character in front of the
        cursor.
        When 'l' is included and it is used after an operator at the end of a
        line (not an empty line) then it will not move to the next line.  This
        makes "dl", "cl", "yl" etc. work normally.

                                                'wildchar' 'wc'
'wildchar' 'wc'         number  (default <Tab>)
                        global
        Character you have to type to start wildcard expansion in the
        command-line, as specified with 'wildmode'.
        More info here: cmdline-completion.
        The character is not recognized when used inside a macro.  See
        'wildcharm' for that.
        Some keys will not work, such as CTRL-C, <CR> and Enter.
        <Esc> can be used, but hitting it twice in a row will still exit
        command-line as a failsafe measure.
        Although 'wc' is a number option, it can be specified as a number, a
        single character, a key-notation (e.g. <Up>, <C-F>) or a letter
        preceded with a caret (e.g. ^F is CTRL-F):
```

```
:set wc=27
:set wc=X
:set wc=^I
set wc=<Tab>
```

```
        'wildchar' also enables completion in search pattern contexts such as
        /, ?, :s, :g, :v, and :vim.  To insert a literal <Tab>
        instead of triggering completion, type <C-V><Tab> or "\t".
        See also 'wildoptions' and wildtrigger().

                                                'wildcharm' 'wcm'
'wildcharm' 'wcm'       number  (default 0)
                        global
        'wildcharm' works exactly like 'wildchar', except that it is
        recognized when used inside a macro.  You can find "spare"
        command-line keys suitable for this option by looking at
        ex-edit-index.  Normally you'll never actually type 'wildcharm',
        just use it in mappings that automatically invoke completion mode,
        e.g.:
```

```
set wcm=<C-Z>
cnoremap ss so $vim/sessions/*.vim<C-Z>
```

```
        Then after typing :ss you can use CTRL-P & CTRL-N.

                                                'wildignore' 'wig'
'wildignore' 'wig'      string  (default "")
                        global
        A list of file patterns.  A file that matches with one of these
        patterns is ignored when expanding wildcards, completing file or
        directory names, and influences the result of expand(), glob() and
        globpath() unless a flag is passed to disable this.
        The pattern is used like with :autocmd, see autocmd-pattern.
        Also see 'suffixes'.
        Example:
```

```
set wildignore=*.o,*.obj
```

```
        The use of :set+= and :set-= is preferred when adding or removing
        a pattern from the list.  This avoids problems when a future version
        uses another default.

                'wildignorecase' 'wic' 'nowildignorecase' 'nowic'
'wildignorecase' 'wic'  boolean (default off)
                        global
        When set case is ignored when completing file names and directories.
        Has no effect when 'fileignorecase' is set.
        Does not apply when the shell is used to expand wildcards, which
        happens when there are special characters.
```

'wildmenu' 'wmnu' 'nowildmenu' 'nowmnu'
'wildmenu' 'wmnu'	boolean (default on)
		global
	When 'wildmenu' is on, command-line completion operates in an enhanced
	mode. On pressing 'wildchar' (usually <Tab>) to invoke completion,
	the possible matches are shown.
	When 'wildoptions' contains "pum", then the completion matches are
	shown in a popup menu. Otherwise they are displayed just above the
	command line, with the first match highlighted (overwriting the status
	line, if there is one).
	Keys that show the previous/next match, such as <Tab> or
	CTRL-P/CTRL-N, cause the highlight to move to the appropriate match.
	'wildmode' must specify "full": "longest" and "list" do not start
	'wildmenu' mode. You can check the current mode with wildmenumode().
	The menu is cancelled when a key is hit that is not used for selecting
	a completion.

	While the menu is active these keys have special meanings:
	CTRL-P		- go to the previous entry
	CTRL-N		- go to the next entry
	<Left> <Right>	- select previous/next match (like CTRL-P/CTRL-N)
	<PageUp>	- select a match several entries back
	<PageDown>	- select a match several entries further
	<Up>		- in filename/menu name completion: move up into
			  parent directory or parent menu.
	<Down>		- in filename/menu name completion: move into a
			  subdirectory or submenu.
	<CR>		- in menu completion, when the cursor is just after a
			  dot: move into a submenu.
	CTRL-E		- end completion, go back to what was there before
			  selecting a match.
	CTRL-Y		- accept the currently selected match and stop
			  completion.

	If you want <Left> and <Right> to move the cursor instead of selecting
	a different match, use this:

```
cnoremap <Left> <Space><BS><Left>
cnoremap <Right> <Space><BS><Right>
```

	hl-WildMenu highlights the current match.

'wildmode' 'wim'
'wildmode' 'wim'	string (default "full")
		global
	Completion mode used for the character specified with 'wildchar'.
	This option is a comma-separated list of up to four parts,
	corresponding to the first, second, third, and fourth presses of
	'wildchar'. Each part is a colon-separated list of completion
	behaviors, which are applied simultaneously during that phase.

	The possible behavior values are:
	""		Only complete (insert) the first match. No further
			matches are cycled or listed.
	"full"		Complete the next full match. Cycles through all
			matches, returning to the original input after the
			last match. If 'wildmenu' is enabled, it will be
			shown.
	"longest"	Complete to the longest common substring. If this
			doesn't extend the input, the next 'wildmode' part is
			used.
	"list"		If multiple matches are found, list all of them.
	"lastused"	When completing buffer names, sort them by most
			recently used (excluding the current buffer). Only
			applies to buffer name completion.
	"noselect"	If 'wildmenu' is enabled, show the menu but do not
			preselect the first item.
	"noinsert"	If 'wildmenu' is enabled, show the menu and preselect
			the first match, but do not insert it in the command
			line. If both "noinsert" and "noselect" are present,
			"noselect" takes precedence.
	If only one match exists, it is completed fully, unless "noselect" or
	"noinsert" is specified.

	Some useful combinations of colon-separated values:
	"longest:full"		Start with the longest common string and show
				'wildmenu' (if enabled). Does not cycle
				through full matches.
	"list:full"		List all matches and complete first match.
	"list:longest"		List all matches and complete till the longest
				common prefix.
	"list:lastused"		List all matches. When completing buffers,
				sort them by most recently used (excluding the
				current buffer).
	"noselect:lastused"	Do not preselect the first item in 'wildmenu'
				if it is active. When completing buffers,
				sort them by most recently used (excluding the
				current buffer).

	Examples:

```
set wildmode=full
```

Complete full match on every press (default behavior)

```
set wildmode=longest,full
```

First press: longest common substring
Second press: cycle through full matches

```
set wildmode=list:full
```

First press: list all matches and complete the first one

```
set wildmode=list,full
```

First press: list matches only
Second press: complete full matches

```
set wildmode=longest,list
```

First press: longest common substring
Second press: list all matches

```
set wildmode=noselect:full
```

First press: show 'wildmenu' without completing or selecting
Second press: cycle full matches

```
set wildmode=noselect:lastused,full
```

Same as above, but buffer matches are sorted by time last used
More info here: cmdline-completion.

'wildoptions' 'wop'
'wildoptions' 'wop'	string (default "pum,tagfile")
global
A list of words that change how cmdline-completion is done.
The following values are supported:
  exacttext	When this flag is present, search pattern completion
(e.g., in /, ?, :s, :g, :v, and :vim)
shows exact buffer text as menu items, without
preserving regex artifacts like position
anchors (e.g., /\<). This provides more intuitive
menu items that match the actual buffer text.
However, searches may be less accurate since the
pattern is not preserved exactly.
By default, Vim preserves the typed pattern (with
anchors) and appends the matched word. This preserves
search correctness, especially when using regular
expressions or with 'smartcase' enabled. However, the
case of the appended matched word may not exactly
match the case of the word in the buffer.
  fuzzy	Use fuzzy-matching to find completion matches. When
this value is specified, wildcard expansion will not
be used for completion. The matches will be sorted by
the "best match" rather than alphabetically sorted.
This will find more matches than the wildcard
expansion. Currently fuzzy matching based completion
is not supported for file and directory names and
instead wildcard expansion is used.
  pum	Display the completion matches using the popup menu in
the same style as the ins-completion-menu. When an
info popup is shown next to the menu, it can be
scrolled by moving the mouse pointer on top of it and
using the scroll wheel.
  tagfile	When using CTRL-D to list matching tags, the kind of
tag and the file of the tag is listed. Only one match
is displayed per line. Often used tag kinds are:
d	#define
f	function

This option does not apply to ins-completion. See 'completeopt' for
that.

'winaltkeys' 'wak'
'winaltkeys' 'wak'	string (default "menu")
global
only used in Win32
Some GUI versions allow the access to menu entries by using the ALT
key in combination with a character that appears underlined in the
menu. This conflicts with the use of the ALT key for mappings and
entering special characters. This option tells what to do:
  no	Don't use ALT keys for menus. ALT key combinations can be
mapped, but there is no automatic handling.
  yes	ALT key handling is done by the windowing system. ALT key
combinations cannot be mapped.
  menu	Using ALT in combination with a character that is a menu
shortcut key, will be handled by the windowing system. Other
keys can be mapped.
If the menu is disabled by excluding 'm' from 'guioptions', the ALT
key is never used for the menu.
This option is not used for <F10>; on Win32.

'winbar' 'wbr'

'winbar' 'wbr' string (default "")
global or local to window global-local

When non-empty, this option enables the window bar and determines its contents. The window bar is a bar that's shown at the top of every window with it enabled. The value of 'winbar' is evaluated like with 'statusline'.

When changing something that is used in 'winbar' that does not trigger it to be updated, use :redrawstatus.

Floating windows do not use the global value of 'winbar'. The window-local value of 'winbar' must be set for a floating window to have a window bar.

This option cannot be set in a modeline when 'modelineexpr' is off.

'winblend' 'winbl'

'winblend' 'winbl' number (default 0)
local to window

Enables pseudo-transparency for a floating window. Valid values are in the range of 0 for fully opaque window (disabled) to 100 for fully transparent background. Values between 0-30 are typically most useful.

UI-dependent. Works best with RGB colors. 'termguicolors'

'winborder'

'winborder' string (default "")
global

Defines the default border style of floating windows. The default value is empty, which is equivalent to "none". Valid values include:

- "bold": Bold line box.
- "double": Double-line box.
- "none": No border.
- "rounded": Like "single", but with rounded corners ("╭" etc.).
- "shadow": Drop shadow effect, by blending with the background.
- "single": Single-line box.
- "solid": Adds padding by a single whitespace cell.
- custom: comma-separated list of exactly 8 entries in clockwise

  order starting from topleft. Each entry may be a single char, a single space (filled with the background), or empty (no border on that side). Example:

```
vim.o.winborder = '+,-,+,|,+,-,+,|'
vim.o.winborder = ',,, ,,,, '  -- left/right padding only
```

'window' 'wi'

'window' 'wi' number (default screen height - 1)
global

Window height used for CTRL-F and CTRL-B when there is only one window and the value is smaller than 'lines' minus one. The screen will scroll 'window' minus two lines, with a minimum of one.
When 'window' is equal to 'lines' minus one CTRL-F and CTRL-B scroll in a much smarter way, taking care of wrapping lines.
When resizing the Vim window, and the value is smaller than 1 or more than or equal to 'lines' it will be set to 'lines' minus 1.
Note: Do not confuse this with the height of the Vim window, use 'lines' for that.

'winfixbuf' 'wfb' 'nowinfixbuf' 'nowfb'

'winfixbuf' 'wfb' boolean (default off)
local to window

If enabled, the window and the buffer it is displaying are paired. For example, attempting to change the buffer with :edit will fail. Other commands which change a window's buffer such as :cnext will also skip any window with 'winfixbuf' enabled. However if an Ex command has a "!" modifier, it can force switching buffers.

'winfixheight' 'wfh' 'nowinfixheight' 'nowfh'

'winfixheight' 'wfh' boolean (default off)
local to window local-noglobal

Keep the window height when windows are opened or closed and 'equalalways' is set. Also for CTRL-W =. Set by default for the preview-window and quickfix-window.
The height may be changed anyway when running out of room.

'winfixwidth' 'wfw' 'nowinfixwidth' 'nowfw'

'winfixwidth' 'wfw'	boolean (default off)
local to window local-noglobal

Keep the window width when windows are opened or closed and 'equalalways' is set. Also for CTRL-W =.
The width may be changed anyway when running out of room.

'winheight' 'wh' E591

'winheight' 'wh'	number (default 1)
global

Minimal number of lines for the current window. This is not a hard minimum, Vim will use fewer lines if there is not enough room. If the focus goes to a window that is smaller, its size is increased, at the cost of the height of other windows.
Set 'winheight' to a small number for normal editing.
Set it to 999 to make the current window fill most of the screen.
Other windows will be only 'winminheight' high. This has the drawback that ":all" will create only two windows. To avoid "vim -o 1 2 3 4" to create only two windows, set the option after startup is done, using the VimEnter event:

```
au VimEnter * set winheight=999
```

Minimum value is 1.
The height is not adjusted after one of the commands that change the height of the current window.
'winheight' applies to the current window. Use 'winminheight' to set the minimal height for other windows.

'winhighlight' 'winhl'

'winhighlight' 'winhl'	string (default "")
local to window

Window-local highlights. Comma-delimited list of highlight group-name pairs "{hl-from}:{hl-to},..." where each {hl-from} is a highlight-groups item to be overridden by {hl-to} group in the window.

Note: highlight namespaces take precedence over 'winhighlight'.
See nvim_win_set_hl_ns() and nvim_set_hl().

Highlights of vertical separators are determined by the window to the left of the separator. The 'tabline' highlight of a tabpage is decided by the last-focused window of the tabpage. Highlights of the popupmenu are determined by the current window. Highlights in the message area cannot be overridden.

Example: show a different color for non-current windows:

```
set winhighlight=Normal:MyNormal,NormalNC:MyNormalNC
```

'winminheight' 'wmh'

'winminheight' 'wmh'	number (default 1)
global

The minimal height of a window, when it's not the current window.
This is a hard minimum, windows will never become smaller.
When set to zero, windows may be "squashed" to zero lines (i.e. just a status bar) if necessary. They will return to at least one line when they become active (since the cursor has to have somewhere to go.)
Use 'winheight' to set the minimal height of the current window.
This option is only checked when making a window smaller. Don't use a large number, it will cause errors when opening more than a few windows. A value of 0 to 3 is reasonable.

'winminwidth' 'wmw'

'winminwidth' 'wmw'	number (default 1)
global

The minimal width of a window, when it's not the current window.
This is a hard minimum, windows will never become smaller.
When set to zero, windows may be "squashed" to zero columns (i.e. just a vertical separator) if necessary. They will return to at least one line when they become active (since the cursor has to have somewhere to go.)
Use 'winwidth' to set the minimal width of the current window.
This option is only checked when making a window smaller. Don't use a large number, it will cause errors when opening more than a few windows. A value of 0 to 12 is reasonable.

'winpinned' 'wp' 'nowinpinned' 'nowp'

'winpinned' 'wp'	boolean (default off)
local to window local-noglobal

If enabled, the window is pinned and will not be closed by :only and :fclose. Only commands specifically targeting the window can close it.

'winwidth' 'wiw' E592

'winwidth' 'wiw'	number (default 20)
global

Minimal number of columns for the current window. This is not a hard minimum, Vim will use fewer columns if there is not enough room. If the current window is smaller, its size is increased, at the cost of the width of other windows. Set it to 999 to make the current window always fill the screen. Set it to a small number for normal editing.
The width is not adjusted after one of the commands to change the width of the current window.

'winwidth' applies to the current window. Use 'winminwidth' to set
the minimal width for other windows.

'wrap' 'nowrap'

'wrap' boolean (default on)
local to window
This option changes how text is displayed. It doesn't change the text
in the buffer, see 'textwidth' for that.
When on, lines longer than the width of the window will wrap and
displaying continues on the next line. When off lines will not wrap
and only part of long lines will be displayed. When the cursor is
moved to a part that is not shown, the screen will scroll
horizontally.
The line will be broken in the middle of a word if necessary. See
'linebreak' to get the break at a word boundary.
To make scrolling horizontally a bit more useful, try this:

```
set sidescroll=5
set listchars+=precedes:<,extends:>
```

See 'sidescroll', 'listchars' and wrap-off.
This option can't be set from a modeline when the 'diff' option is
on.
If 'nowrap' was set from a modeline or in the sandbox, '>' is used
as the lcs-extends character regardless of the value of the 'list'
and 'listchars' options. This is to prevent malicious code outside
the viewport from going unnoticed. Use :setlocal nowrap manually
afterwards to disable this behavior.

'wrapmargin' 'wm'

'wrapmargin' 'wm' number (default 0)
local to buffer
Number of characters from the right window border where wrapping
starts. When typing text beyond this limit, an <EOL> will be inserted
and inserting continues on the next line.
Options that add a margin, such as 'number' and 'foldcolumn', cause
the text width to be further reduced.
When 'textwidth' is non-zero, this option is not used.
See also 'formatoptions' and ins-textwidth.

'wrapscan' 'ws' 'nowrapscan' 'nows' E384 E385

'wrapscan' 'ws' boolean (default on)
global
Searches wrap around the end of the file. Also applies to]s and
[s, searching for spelling mistakes.

'write' 'nowrite'

'write' boolean (default on)
global
Allows writing files. When not set, writing a file is not allowed.
Can be used for a view-only mode, where modifications to the text are
still allowed. Can be reset with the -m or -M command line
argument. Filtering text is still possible, even though this requires
writing a temporary file.

'writeany' 'wa' 'nowriteany' 'nowa'

'writeany' 'wa' boolean (default off)
global
Allows writing to any file with no need for "!" override.

'writebackup' 'wb' 'nowritebackup' 'nowb'

'writebackup' 'wb' boolean (default on)
global
Make a backup before overwriting a file. The backup is removed after
the file was successfully written, unless the 'backup' option is
also on.
WARNING: Switching this option off means that when Vim fails to write
your buffer correctly and then, for whatever reason, Vim exits, you
lose both the original file and what you were writing. Only reset
this option if your file system is almost full and it makes the write
fail (and make sure not to exit Vim until the write was successful).
See backup-table for another explanation.
When the 'backupskip' pattern matches, a backup is not made anyway.
Depending on 'backupcopy' the backup is a new file or the original
file renamed (and a new file is written).

'writedelay' 'wd'

'writedelay' 'wd' number (default 0)
global
Only takes effect together with 'redrawdebug'.
The number of milliseconds to wait after each line or each flush

Using Vim packages

A Vim "package" is a directory that contains plugins. Compared to normal plugins, a package can...
- be downloaded as an archive and unpacked in its own directory, so the files are not mixed with files of other plugins.
- be a git, mercurial, etc. repository, thus easy to update.
- contain multiple plugins that depend on each other.
- contain plugins that are automatically loaded on startup ("start" packages, located in "pack/*/start/*") and ones that are only loaded when needed with :packadd ("opt" packages, located in "pack/*/opt/*").

runtime-search-path

Nvim searches for :runtime files in:
- 1. all paths in 'runtimepath'
- 2. all "pack/*/start/*" dirs

Note that the "pack/*/start/*" paths are not explicitly included in 'runtimepath', so they will not be reported by ":set rtp" or "echo &rtp". Scripts can use nvim_list_runtime_paths() to list all used directories, and nvim_get_runtime_file() to query for specific files or sub-folders within the runtime path. Example:

```
" List all runtime dirs and packages with Lua paths.
:echo nvim_get_runtime_file("lua/", v:true)
```

Using a package and loading automatically

Let's assume your Nvim files are in "~/.local/share/nvim/site" and you want to add a package from a zip archive "/tmp/foopack.zip":

```
% mkdir -p ~/.local/share/nvim/site/pack/foo
% cd ~/.local/share/nvim/site/pack/foo
% unzip /tmp/foopack.zip
```

The directory name "foo" is arbitrary, you can pick anything you like.

You would now have these files under ~/.local/share/nvim/site:

```
pack/foo/README.txt
pack/foo/start/foobar/plugin/foo.vim
pack/foo/start/foobar/syntax/some.vim
pack/foo/opt/foodebug/plugin/debugger.vim
```

On startup after processing your config, Nvim scans all directories in 'packpath' for plugins in "pack/*/start/*", then loads the plugins.

To allow for calling into package functionality while parsing your vimrc, :colorscheme and autoload will both automatically search under 'packpath' as well in addition to 'runtimepath'. See the documentation for each for details.

In the example Nvim will find "pack/foo/start/foobar/plugin/foo.vim" and load it.

If the "foobar" plugin kicks in and sets the 'filetype' to "some", Nvim will find the syntax/some.vim file, because its directory is in the runtime search path.

Nvim will also load ftdetect files, if there are any.

Note that the files under "pack/foo/opt" are not loaded automatically, only the ones under "pack/foo/start". See pack-add below for how the "opt" directory is used.

Loading packages automatically will not happen if loading plugins is disabled, see load-plugins.

To load packages earlier, so that plugin/ files are sourced: :packloadall This also works when loading plugins is disabled. The automatic loading will only happen once.

If the package has an "after" directory, that directory is added to the end of 'runtimepath', so that anything there will be loaded later.

Using a single plugin and loading it automatically

If you don't have a package but a single plugin, you need to create the extra directory level:

```
% mkdir -p ~/.local/share/nvim/site/pack/foo/start/foobar
% cd ~/.local/share/nvim/site/pack/foo/start/foobar
% unzip /tmp/someplugin.zip
```

You would now have these files:

```
pack/foo/start/foobar/plugin/foo.vim
pack/foo/start/foobar/syntax/some.vim
```

From here it works like above.

Optional plugins

pack-add

To load an optional plugin from a pack use the `:packadd` command:

```
:packadd foodebug
```

This searches for "pack/*/opt/foodebug" in 'packpath' and will find ~/.local/share/nvim/site/pack/foo/opt/foodebug/plugin/debugger.vim and source it.

This could be done if some conditions are met. For example, depending on whether Nvim supports a feature or a dependency is missing.

You can also load an optional plugin at startup, by putting this command in your config:

```
:packadd! foodebug
```

The extra "!" is so that the plugin isn't loaded if Nvim was started with --noplugin.

It is perfectly normal for a package to only have files in the "opt" directory. You then need to load each plugin when you want to use it.

Where to put what

Since color schemes, loaded with `:colorscheme`, are found below "pack/*/start" and "pack/*/opt", you could put them anywhere. We recommend you put them below "pack/*/opt", for example "~/.config/nvim/pack/mycolors/opt/dark/colors/very_dark.vim".

Filetype plugins should go under "pack/*/start", so that they are always found. Unless you have more than one plugin for a file type and want to select which one to load with `:packadd`. E.g. depending on the compiler version:

```
if foo_compiler_version > 34
  packadd foo_new
else
  packadd foo_old
endif
```

The "after" directory is most likely not useful in a package. It's not disallowed though.

Creating Vim packages

package-create

This assumes you write one or more plugins that you distribute as a package.

If you have two unrelated plugins you would use two packages, so that Vim users can choose what they include or not. Or you can decide to use one package with optional plugins, and tell the user to add the preferred ones with `:packadd`.

Decide how you want to distribute the package. You can create an archive or you could use a repository. An archive can be used by more users, but is a bit harder to update to a new version. A repository can usually be kept up-to-date easily, but it requires a program like "git" to be available. You can do both, github can automatically create an archive for a release.

Your directory layout would be like this:

```
start/foobar/plugin/foo.vim          " always loaded, defines commands
start/foobar/plugin/bar.vim          " always loaded, defines commands
start/foobar/autoload/foo.vim        " loaded when foo command used
start/foobar/doc/foo.txt             " help for foo.vim
start/foobar/doc/tags                " help tags
opt/fooextra/plugin/extra.vim        " optional plugin, defines commands
opt/fooextra/autoload/extra.vim      " loaded when extra command used
opt/fooextra/doc/extra.txt           " help for extra.vim
opt/fooextra/doc/tags                " help tags
```

This allows for the user to do:

```
mkdir ~/.local/share/nvim/site/pack
cd ~/.local/share/nvim/site/pack
git clone https://github.com/you/foobar.git myfoobar
```

Here "myfoobar" is a name that the user can choose, the only condition is that it differs from other packages.

In your documentation you explain what the plugins do, and tell the user how to load the optional plugin:

```
:packadd! fooextra
```

You could add this packadd command in one of your plugins, to be executed when the optional plugin is needed.

Run the `:helptags` command to generate the doc/tags file. Including this generated file in the package means that the user can drop the package in the pack directory and the help command works right away. Don't forget to re-run the command after changing the plugin help:

```
:helptags path/start/foobar/doc
:helptags path/opt/fooextra/doc
```

Dependencies between plugins

packload-two-steps

Suppose you have two plugins that depend on the same functionality. You can put the common functionality in an autoload directory, so that it will be found automatically. Your package would have these files:

pack/foo/start/one/plugin/one.vim

```
call foolib#getit()
```

pack/foo/start/two/plugin/two.vim

```
call foolib#getit()
```

pack/foo/start/lib/autoload/foolib.vim

```
func foolib#getit()
```

This works, because start packages will be searched for autoload files, when sourcing the plugins.

Plugin manager

vim.pack

Install, update, and delete external plugins. **WARNING:** It is still considered experimental, yet should be stable enough for daily use.

Manages plugins only in a dedicated vim.pack-directory (see packages): `site/pack/core/opt` subdirectory of "data" standard-path. Subdirectory `site` of "data" standard path needs to be part of 'packpath'. It usually is, but might not be in cases like --clean or setting $XDG_DATA_HOME during startup. Plugin's subdirectory name matches plugin's name in specification. It is assumed that all plugins in the directory are managed exclusively by `vim.pack`.

Uses Git to manage plugins and requires present `git` executable. Target plugins should be Git repositories with versions as named tags following semver convention `v<major>.<minor>.<patch>` (with or without `v` prefix). Like `v1.2.0` or `1.2.0`, but not `1.2` or `v1`.

The latest state of all managed plugins is stored inside a vim.pack-lockfile located at 'packlockfile'. It is a JSON file that is used to persistently track data about plugins. For a more robust config treat lockfile like its part: put under version control, etc. In this case all plugins from the lockfile will be installed at once (in alphabetical order) and at lockfile's revision (instead of inferring from `version`). This is done on the very first `vim.pack` function call to ensure that lockfile is aligned with what is actually on the disk. Lockfile should not be edited by hand. Corrupted data for installed plugins is repaired (including after deleting whole file), but `version` fields will be missing for not yet added plugins.

vim.pack-examples

Basic install and management

- Add vim.pack.add() call(s) to 'init.lua':

```
vim.pack.add({
  -- Install "plugin1" and use default branch (usually `main` or `master`)
  'https://github.com/user/plugin1',

  -- Same as above, but using a table (allows setting other options)
  { src = 'https://github.com/user/plugin1' },

  -- Specify plugin's name (here the plugin will be called "plugin2"
  -- instead of "generic-name")
  { src = 'https://github.com/user/generic-name', name = 'plugin2' },

  -- Specify version to follow during install and update
  {
    src = 'https://github.com/user/plugin3',
    -- Version constraint, see |vim.version.range()|
    version = vim.version.range('1.0'),
  },
  {
    src = 'https://github.com/user/plugin4',
    -- Git branch, tag, or commit hash
    version = 'main',
  },
})

-- Plugin's code can be used directly after `add()`
plugin1 = require('plugin1')
```

- Restart Nvim (for example, with :restart). Plugins that were not yet installed will be available on disk after `add()` call. Their revision is taken from vim.pack-lockfile (if present) or inferred from the `version`.
- To update all plugins with new changes:
  - Execute :packupdate. This will download updates from source and show confirmation buffer in a separate tabpage.
  - Review changes. To confirm all updates execute :write. To discard updates execute :quit.
  - (Optionally) :restart to start using code from updated plugins.

Use shorter source

Create custom Lua helpers:

```
local gh = function(x) return 'https://github.com/' .. x end
local cb = function(x) return 'https://codeberg.org/' .. x end
vim.pack.add({ gh('user/plugin1'), cb('user/plugin2') })
```

Another approach is to utilize Git's `insteadOf` configuration:

- `git config --global url."https://github.com/".insteadOf "gh:"`
- `git config --global url."https://codeberg.org/".insteadOf "cb:"`
- In 'init.lua': `vim.pack.add({ 'gh:user/plugin1', 'cb:user/plugin2' })`. These sources will be used verbatim in vim.pack-lockfile, so reusing the config on different machine will require the same Git configuration.

Explore installed plugins

- `:packupdate ++offline`
- Navigate between plugins with `[[` and `]]`. List them with g0 (vim.lsp.buf.document_symbol()).

Switch plugin's version and/or source

- Update 'init.lua' for plugin to have desired `version` and/or `src`. Let's say, the switch is for plugin named 'plugin1'.
- :restart. The plugin's state on disk (revision and/or tracked source) is not yet changed. Only plugin's `version` in vim.pack-lockfile is updated.
- Execute `:packupdate plugin1`. The plugin's source is updated. If only switching version, also pass the `++offline` argument.
- Review changes and either confirm or discard them. If discarded, revert `version` change in 'init.lua' as well or you will be prompted again next time you run `:packupdate`.

Freeze plugin from being updated

- Update 'init.lua' for plugin to have `version` set to current revision. Get it from vim.pack-lockfile (plugin's field `rev`; looks like `abc12345`).
- :restart.

Unfreeze plugin to start receiving updates

- Update 'init.lua' for plugin to have `version` set to whichever version you want it to be updated.

- :restart.

Revert plugin after an update

- Revert the vim.pack-lockfile to the state before the update:
  - If Git tracked: `git checkout HEAD -- nvim-pack-lock.json`
  - If not tracked: examine log file ("nvim-pack.log" at "log" standard-path), locate the revisions before the latest update, and (carefully) adjust current lockfile to have those revisions.
- :restart.
- `:packupdate ++offline ++lockfile plugin`. Read and confirm.

Synchronize config across machines

- On main machine:
  - Add vim.pack-lockfile to VCS.
  - Push to the remote server.
- On secondary machine:
  - Pull from the server.
  - :restart. New plugins (not present locally, but present in the lockfile) are installed at proper revision. If some installation has failed but you know it should not (like due to bad Internet connection), revert vim.pack-lockfile and :restart again.
  - `:packupdate ++lockfile`. Read and confirm.
  - Manually delete outdated plugins (present locally, but were not present in the lockfile prior to restart) with `:packdel plugin`. They can be located by examining the VCS difference of the lockfile (`git diff -- nvim-pack-lock.json` for Git).

Remove plugins from disk

- Remove plugin specs from vim.pack.add() calls in 'init.lua' or they will be reinstalled later.
- :restart.
- Use :packdel with plugin names to remove. Use `:packdel ++all` to delete all inactive plugins.

Check for pending updates

- Run `vim.pack.get(nil, { offline = false })` and check the output for items with different `rev` and `rev_to` fields. To not download new updates from source, use plain `vim.pack.get()`.

Check for issues

- Run `:checkhealth vim.pack` and follow recommendations in case of detected issues.

Commands vim.pack-commands E5807

:packu :packupdate E5808 :packu[pdate][!] [++offline] [++lockfile] [name]

Interactively update the specified plugins. Skips confirmation when `!` is given. If no plugin names are provided, update all plugins.

When `++offline` is given, skip downloading new updates.

When `++lockfile` is given, use revisions from the lockfile.

:packd :packdel E5809 E5810 E5811 :packd[el][!] {name}

Remove the specified plugins. Can only remove inactive plugins unless `!` is given.

:packd[el][!] ++all

Remove all inactive plugins. When `!` is given, instead remove all plugins.

vim.pack-events

Performing actions via `vim.pack` functions can trigger these events:

- PackChangedPre - before trying to change plugin's state.
- PackChanged - after plugin's state has changed.

Events are triggered in bulk respecting order of plugins in which they are supplied. First all `PackChangedPre`, then perform all actions, and only after

- all `PackChanged` for successful actions. This provides more control for connected plugins, like by specifying dependencies before the plugin itself.

The event-data has these keys (type: `vim.event.packchanged.data`):

- `active` - whether plugin was added via vim.pack.add() to current session.
- `kind` - one of "install" (install on disk; before loading), "update" (update already installed plugin; might be not loaded), "delete" (delete from disk).
- `spec` - plugin's specification with defaults made explicit.
- `path` - full path to plugin's directory.

These events can be used to execute plugin hooks. For example:

```
local hooks = function(ev)
  -- Use available |event-data|
  local name, kind = ev.data.spec.name, ev.data.kind

  -- Run build script after plugin's code has changed
  if name == 'plug-1' and (kind == 'install' or kind == 'update') then
    -- Append `:wait()` if you need synchronous execution
    vim.system({ 'make' }, { cwd = ev.data.path })
  end

  -- If action relies on code from the plugin (like user command or
  -- Lua code), make sure to explicitly load it first
  if name == 'plug-2' and kind == 'update' then
    if not ev.data.active then
      vim.cmd.packadd('plug-2')
    end
    vim.cmd('PlugTwoUpdate')
    require('plug2').after_update()
  end
end

-- If hooks need to run on install, run this before `vim.pack.add()`
-- To act on install from lockfile, run before very first `vim.pack.add()`
vim.api.nvim_create_autocmd('PackChanged', { callback = hooks })
```

vim.pack-manifest

Plugins can come with a special top level `pkg.json` manifest file with extra information. If present, `vim.pack` uses it for improved user experience:

- Apply :source for scripts after triggering corresponding vim.pack-events. This allows plugins to define hooks that will be executed during plugin's lifetime. Sourcing is done with special context:
  - The current-directory is temporarily set to plugin's root (to make it easier to run vim.system() commands).
  - Plugin's path is temporarily ensured to be inside 'runtimepath' (so script can use require() with plugin's module, possibly with explicit package.loaded reset inside `"update"` scripts).
- Running :checkhealth for `vim.pack` will perform extra checks to ensure healthy plugin installation.

Full specification see at https://packspec.org/. See also vim.pack.Manifest. A simple example:

```
{
 "name": "best-plugin.nvim",
 "description": "The best plugin for Neovim",
 "engines": {
     "nvim": ">=0.13.0",
     "vim": ">=9.1.0"
 },
 "scripts": {
   "install": "scripts/install.lua",
   "preupdate": "scripts/preupdate.vim",
   "update": "scripts/update.vim",
   "preuninstall": "scripts/preuninstall.lua"
 }
}
```

vim.pack.Manifest

Fields:

- `{description}?` (`string`) Plugin description
- `{engines}?` (`table`) Supported engine versions. Values should be vim.version.range() compatible specs.
  - `{nvim}?` (`string`) Version range for Nvim.
  - `{vim}?` (`string`) Version range for Vim.
- `{name}?` (`string`) Plugin name
- `{scripts}?` (`table`) Script locations (relative to plugin's root) to :source after triggering corresponding vim.pack-events.
  - `{install}?` (`string`) Post install script.
  - `{preuninstall}?` (`string`) Pre delete script.
  - `{preupdate}?` (`string`) Pre update script.
  - `{update}?` (`string`) Post update script.

vim.pack.Spec

Fields:

- `{data}?` (any) Arbitrary data associated with a plugin.
- `{name}?` (`string`) Name of plugin. Will be used as directory name. Default: `src` repository name.
- `{src}` (`string`) URI from which to install and pull updates. Any format supported by `git clone` is allowed.
- `{version}?` (`string|vim.VersionRange`) Version to use for install and updates. Can be:
  - `nil` (no value, default) to use repository's default branch (usually `main` or `master`).
  - String to use specific branch, tag, or commit hash.
  - Output of vim.version.range() to install the greatest/last semver tag inside the version constraint.

add({specs}, {opts}) vim.pack.add()

Add plugin to current session

- For each specification check that plugin exists on disk in vim.pack-directory:
  - If exists, check if its `src` is the same as input. If not - delete immediately to clean install from the new source. Otherwise do nothing.
  - If doesn't exist, install it by downloading from `src` into `name` subdirectory (via partial blobless `git clone`) and update revision to match `version` (via `git checkout`). Plugin will not be on disk if any step resulted in an error.
- For each plugin execute :packadd (or customizable `load` function) making it reachable by Nvim.

Notes:
- Installation is done in parallel, but waits for all to finish before continuing next code execution.
- If plugin is already present on disk, there are no checks about its current revision. The specified `version` can be not the one actually present on disk. Execute vim.pack.update() to synchronize.
- Adding plugin second and more times during single session does nothing: only the data from the first adding is registered.

Parameters:
- `{specs}` (`(string|vim.pack.Spec)[]`) List of plugin specifications. String item is treated as `src`.
- `{opts}` (`table?`) A table with the following fields:
  - `{confirm}?` (`boolean`) Whether to ask user to confirm initial install. Default `true`.
  - `{load}?` (`boolean|fun(plug_data: {spec: vim.pack.Spec, path: string})`) Load `plugin/` files and `ftdetect/` scripts. If `false`, works like `:packadd!`. If function, called with plugin data and is fully responsible for loading plugin. Default `false` during init.lua sourcing and `true` afterwards.

del({names}, {opts}) vim.pack.del()
Remove plugins from disk

Parameters:
- `{names}` (`string[]`) List of plugin names to remove from disk. Must be managed by vim.pack, not necessarily already added to current session.
- `{opts}` (`table?`) A table with the following fields:
  - `{force}?` (`boolean`) Whether to allow deleting an active plugin. Default `false`.

get({names}, {opts}) vim.pack.get()
Gets vim.pack plugin info, optionally filtered by `names`.

Parameters:
- `{names}` (`string[]?`) List of plugin names. Default: all plugins managed by vim.pack.
- `{opts}` (`table?`) A table with the following fields:
  - `{info}?` (`boolean`) Whether to include extra plugin info. Default `true`.
  - `{offline}?` (`boolean`) Whether to skip downloading new updates. Requires `info=true`. Default: `true`.

Return:
(`table[]`) A list of objects with the following fields:
- `{active}` (`boolean`) Whether plugin was added via vim.pack.add() to current session.
- `{branches}?` (`string[]`) Available Git branches (first is default). Missing if `info=false`.
- `{manifest}?` (`vim.pack.Manifest`) Data from the vim.pack-manifest. Empty in case of reading error. Missing if `info=false`.
- `{path}` (`string`) Plugin's path on disk.
- `{rev}` (`string`) Current Git revision. Taken from vim.pack-lockfile if `info=false`.
- `{rev_to}?` (`string`) Git revision of a pending update. The same as used during vim.pack.update() and which points to a resolved `spec.version`. Missing if `info=false`.
- `{spec}` (`vim.pack.SpecResolved`) A vim.pack.Spec with resolved `name`.
- `{tags}?` (`string[]`) Available Git tags. Missing if `info=false`.

update({names}, {opts}) vim.pack.update()
Update plugins
- Download new changes from source.
- Infer update info (current/target revisions, changelog, etc.).
- If `force` is `false` (default), show confirmation buffer. If `force` is `true`, make updates right away.

Notes:
- Every actual update is logged in "nvim-pack.log" file inside "log" standard-path.
- It doesn't update source's default branch if it has changed (like from `master` to `main`). To have `version = nil` point to a new default branch, re-install the plugin (vim.pack.del() + vim.pack.add()).

Confirmation buffer

The goal of the confirmation buffer is to show update details for the user to read, confirm (execute :write) or deny (execute :quit) the update.

Pending changes starting with > will be applied while the ones starting with < will be reverted.

There are convenience buffer-local mappings:
-]] and [[to navigate through plugin sections.

Some features are provided via LSP:
- 'textDocument/documentLink' - compute links for plugin paths, sources, commits, and tags. Makes a best effort educated guess about a link structure. Use gx to open a link to an object at cursor.
- 'textDocument/documentSymbol' (g0 via lsp-defaults or vim.lsp.buf.document_symbol()) - show structure of the buffer.
- 'textDocument/hover' (K via lsp-defaults or vim.lsp.buf.hover()) - show more information at cursor. Like details of particular pending change or newer tag.
- 'textDocument/codeAction' (`gra` via lsp-defaults or vim.lsp.buf.code_action()) - show code actions relevant for "plugin at cursor". Like "delete" (after extra confirmation for active plugins), "update" or "skip updating" (if there are pending updates).

Parameters:
- `{names}` (`string[]?`) List of plugin names to update. Must be managed by vim.pack, not necessarily already added to current session. Default: names of all plugins managed by vim.pack.
- `{opts}` (`table?`) A table with the following fields:
  - `{force}?` (`boolean`) Whether to skip confirmation and make updates immediately. Default `false`.
  - `{offline}?` (`boolean`) Whether to skip downloading new updates. Default: `false`.
  - `{target}?` (`string`) How to compute a new plugin revision. One of:
    - "version" (default): use latest revision matching `version` from plugin specification.
    - "lockfile": use revision from the lockfile. For reverting or performing controlled update.

Patterns and search commands

The very basics can be found in section 03.9 of the user manual. A few more explanations are in chapter 27 usr_27.txt.

1. Search commands search-commands

/

/{pattern}[/]<CR> Search forward for the [count]'th occurrence of {pattern} exclusive.

/{pattern}/{offset}<CR> Search forward for the [count]'th occurrence of {pattern} and go {offset} lines up or down. linewise.

/<CR>

/<CR> Search forward for the [count]'th occurrence of the latest used pattern last-pattern with latest used {offset}.

//{offset}<CR> Search forward for the [count]'th occurrence of the latest used pattern last-pattern with new {offset}. If {offset} is empty no offset is used.

?

?{pattern}[?]<CR> Search backward for the [count]'th previous occurrence of {pattern} exclusive.

?{pattern}?{offset}<CR> Search backward for the [count]'th previous occurrence of {pattern} and go {offset} lines up or down linewise.

?<CR>

?<CR> Search backward for the [count]'th occurrence of the latest used pattern last-pattern with latest used {offset}.

??{offset}<CR> Search backward for the [count]'th occurrence of the latest used pattern last-pattern with new {offset}. If {offset} is empty no offset is used.

n

n Repeat the latest "/" or "?" [count] times.
If the cursor doesn't move the search is repeated with count + 1.
last-pattern

N

N Repeat the latest "/" or "?" [count] times in opposite direction. last-pattern

star E348 E349

* Search forward for the [count]'th occurrence of the word nearest to the cursor. The word used for the search is the first of:
1. the keyword under the cursor 'iskeyword'

2. the first keyword after the cursor, in the

current line
3. the non-blank word under the cursor

4. the first non-blank word after the cursor,

in the current line
Only whole keywords are searched for, like with the command "/\<keyword\>". exclusive
'ignorecase' is used, 'smartcase' is not.

v_star-default

{Visual}* In Visual mode, search forward for the current selection. default-mappings

#

Same as "*", but search backward. The pound sign (character 163) also works. If the "#" key works as backspace, try using "stty erase <BS>" before starting Vim (<BS> is CTRL-H or a real backspace).

v_#-default

{Visual}# In Visual mode, search backward for the current selection. default-mappings

gstar

g* Like "*", but don't put "\<" and "\>" around the word.
This makes the search also find matches that are not a
whole word.

g#

g# Like "#", but don't put "\<" and "\>" around the word.
This makes the search also find matches that are not a
whole word.

gd

gd Goto local Declaration. When the cursor is on a local
variable, this command will jump to its declaration.
This was made to work for C code, in other languages
it may not work well.
First Vim searches for the start of the current
function, just like "[[". If it is not found the
search stops in line 1. If it is found, Vim goes back
until a blank line is found. From this position Vim
searches for the keyword under the cursor, like with
"*", but lines that look like a comment are ignored
(see 'comments' option).
Note that this is not guaranteed to work, Vim does not
really check the syntax, it only searches for a match
with the keyword. If included files also need to be
searched use the commands listed in include-search.
After this command n searches forward for the next
match (not backward).

gD

gD Goto global Declaration. When the cursor is on a
global variable that is defined in the file, this
command will jump to its declaration. This works just
like "gd", except that the search for the keyword
always starts in line 1.

1gd

1gd Like "gd", but ignore matches inside a {} block that
ends before the cursor position.

1gD

1gD Like "gD", but ignore matches inside a {} block that
ends before the cursor position.

:noh[lsearch] :noh :nohlsearch
Stop the highlighting for the 'hlsearch' option. It
is automatically turned back on when using a search
command, or setting the 'hlsearch' option.
This command doesn't work in an autocommand, because
the highlighting state is saved and restored when
executing autocommands autocmd-searchpat.
Same thing for when invoking a user function.

While typing the search pattern the current match will be shown if the
'incsearch' option is on. Remember that you still have to finish the search
command with <CR> to actually position the cursor at the displayed match. Or
use <Esc> to abandon the search.

nohlsearch-auto

All matches for the last used search pattern will be highlighted if you set
the 'hlsearch' option. This can be suspended with the :nohlsearch command
or auto suspended with nohlsearch plugin. See nohlsearch-install.

When 'shortmess' does not include the "S" flag, Vim will automatically show an
index, on which the cursor is. This can look like this:

```
[1/5]           Cursor is on first of 5 matches.
[1/>99] Cursor is on first of more than 99 matches.
[>99/>99]       Cursor is after 99 match of more than 99 matches.
[?/??]  Unknown how many matches exists, generating the
              statistics was aborted because of search timeout.
```

Note: the count does not take offset into account.

When no match is found you get the error: E486 Pattern not found
Note that for the :global command, you get a normal message "Pattern not
found", for Vi compatibility.
For the :s command the "e" flag can be used to avoid the error message
:s_flags.

search-options

The following options affect how a search is performed in Vim:

'hlsearch'	highlight matches
'ignorecase'	ignore case when searching
'imsearch'	use IME when entering the search pattern
'incsearch'	show matches incrementally as the pattern is typed
'maxsearchcount'	maximum number for the search count shm-S
'shortmess'	suppress messages shm-s; show search count shm-S

'smartcase' override 'ignorecase' if pattern contains uppercase
'wrapscan' continue searching from the start of the file

search-offset {offset}

These commands search for the specified pattern. With "/" and "?" an additional offset may be given. There are two types of offsets: line offsets and character offsets.

The offset gives the cursor position relative to the found match:

```
[num]       [num] lines downwards, in column 1
+[num]      [num] lines downwards, in column 1
-[num]      [num] lines upwards, in column 1
e[+num]     [num] characters to the right of the end of the match
e[-num]     [num] characters to the left of the end of the match
s[+num]     [num] characters to the right of the start of the match
s[-num]     [num] characters to the left of the start of the match
b[+num]     [num] identical to s[+num] above (mnemonic: begin)
b[-num]     [num] identical to s[-num] above (mnemonic: begin)
;{pattern}  perform another search, see //;
```

If a '-' or '+' is given but [num] is omitted, a count of one will be used. When including an offset with 'e', the search becomes inclusive (the character the cursor lands on is included in operations).

Examples:

pattern	cursor position
/test/+1	one line below "test", in column 1
/test/e	on the last t of "test"
/test/s+2	on the 's' of "test"
/test/b-3	three characters before "test"

If one of these commands is used after an operator, the characters between the cursor position before and after the search is affected. However, if a line offset is given, the whole lines between the two cursor positions are affected.

An example of how to search for matches with a pattern and change the match with another word:

```
/foo<CR>        find "foo"
c//e<CR>        change until end of match
bar<Esc>        type replacement
//<CR>          go to start of next match
c//e<CR>        change until end of match
beep<Esc>       type another replacement
                etc.
```

//; E386

A very special offset is ';' followed by another search command. For example:

```
/test 1/;/test
/test.*/+1;?ing?
```

The first one first finds the next occurrence of "test 1", and then the first occurrence of "test" after that.

This is like executing two search commands after each other, except that:

- It can be used as a single motion command after an operator.
- The direction for a following "n" or "N" command comes from the first search command.
- When an error occurs the cursor is not moved at all.

last-pattern

The last used pattern and offset are remembered. They can be used to repeat the search, possibly in another direction or with another count. Note that two patterns are remembered: One for "normal" search commands and one for the substitute command ":s". Each time an empty pattern is given, the previously used pattern is used. However, if there is no previous search command, a previous substitute pattern is used, if possible.

The 'magic' option sticks with the last used pattern. If you change 'magic', this will not change how the last used pattern will be interpreted. The 'ignorecase' option does not do this. When 'ignorecase' is changed, it will result in the pattern to match other text.

All matches for the last used search pattern will be highlighted if you set the 'hlsearch' option.

To clear the last used search pattern:

```
:let @/ = ""
```

This will not set the pattern to an empty string, because that would match everywhere. The pattern is really cleared, like when starting Vim.

The search usually skips matches that don't move the cursor. Whether the next match is found at the next character or after the skipped match depends on the 'c' flag in 'cpoptions'. See cpo-c.

```
           with 'c' flag:   "/..." advances 1 to 3 characters
        without 'c' flag:   "/..." advances 1 character
```

The unpredictability with the 'c' flag is caused by starting the search in the first column, skipping matches until one is found past the cursor position.

When searching backwards, searching starts at the start of the line, using the 'c' flag in 'cpoptions' as described above. Then the last match before the cursor position is used.

In Vi the ":tag" command sets the last search pattern when the tag is searched for. In Vim this is not done, the previous search pattern is still remembered, unless the 't' flag is present in 'cpoptions'. The search pattern is always put in the search history.

If the 'wrapscan' option is on (which is the default), searches wrap around the end of the buffer. If 'wrapscan' is not set, the backward search stops at the beginning and the forward search stops at the end of the buffer. If 'wrapscan' is set and the pattern was not found the error message "pattern not found" is given, and the cursor will not be moved. If 'wrapscan' is not set the message becomes "search hit BOTTOM without match" when searching forward, or "search hit TOP without match" when searching backward. If wrapscan is set and the search wraps around the end of the file the message "search hit TOP, continuing at BOTTOM" or "search hit BOTTOM, continuing at TOP" is given when searching backwards or forwards respectively. This can be switched off by setting the 's' flag in the 'shortmess' option. The highlight method 'w' is used for this message (default: standout).

search-range

You can limit the search command "/" to a certain range of lines by including \%>l items. For example, to match the word "limit" below line 199 and above line 300:

```
/\%>199l\%<300llimit
```

Also see /\%>l.

Another way is to use the ":substitute" command with the 'c' flag. Example:

```
:.,300s/Pattern//gc
```

This command will search from the cursor position until line 300 for "Pattern". At the match, you will be asked to type a character. Type 'q' to stop at this match, type 'n' to find the next match.

The "*", "#", "g*" and "g#" commands look for a word near the cursor in this order, the first one that is found is used:

- The keyword currently under the cursor.
- The first keyword to the right of the cursor, in the same line.
- The WORD currently under the cursor.
- The first WORD to the right of the cursor, in the same line.

```
The keyword may only contain letters and characters in 'iskeyword'.
The WORD may contain any non-blanks (<Tab>s and/or <Space>s).
Note that if you type with ten fingers, the characters are easy to remember:
the "#" is under your left hand middle finger (search to the left and up) and
the "*" is under your right hand middle finger (search to the right and down).
(this depends on your keyboard layout though).
```

E956

In very rare cases a regular expression is used recursively. This can happen when executing a pattern takes a long time and when checking for messages on channels a callback is invoked that also uses a pattern or an autocommand is triggered. In most cases this should be fine, but if a pattern is in use when it's used again it fails. Usually this means there is something wrong with the pattern.

2. The definition of a pattern

search-pattern pattern [pattern]

regular-expression regexp Pattern
E383 E476

For starters, read chapter 27 of the user manual usr_27.txt.

/bar /\bar /pattern

1. A pattern is one or more branches, separated by "\|". It matches anything

   that matches one of the branches. Example: "foo\|beep" matches "foo" and matches "beep". If more than one branch matches, the first one is used.

```
  pattern ::=      branch
               or  branch \| branch
               or  branch \| branch \| branch
               etc.
```

/branch /\&

1. A branch is one or more concats, separated by "\&". It matches the last

    concat, but only if all the preceding concats also match at the same
    position. Examples:

```
"foobeep\&..." matches "foo" in "foobeep".
".*Peter\&.*Bob" matches in a line containing both "Peter" and "Bob"
```

```
    branch ::=       concat
                 or  concat \& concat
                 or  concat \& concat \& concat
                 etc.
```

/concat

1. A concat is one or more pieces, concatenated. It matches a match for the

    first piece, followed by a match for the second piece, etc. Example:
    "f[0-9]b", first matches "f", then a digit and then "b".

```
  concat  ::=      piece
               or  piece piece
               or  piece piece piece
               etc.
```

/piece

1. A piece is an atom, possibly followed by a multi, an indication of how many

    times the atom can be matched. Example: "a*" matches any sequence of "a"
    characters: "", "a", "aa", etc. See /multi.

```
  piece   ::=      atom
               or  atom  multi
```

/atom

1. An atom can be one of a long list of items. Many atoms match one character

    in the text. It is often an ordinary character or a character class.
    Parentheses can be used to make a pattern into an atom. The "\z(\)"
    construct is only for syntax highlighting.

```
  atom    ::=      ordinary-atom              /ordinary-atom
               or  \( pattern \)              /\(
               or  \%( pattern \)             /\%(
               or  \z( pattern \)             /\z(
```

/\%#= two-engines NFA

Vim includes two regexp engines:

1. An old, backtracking engine that supports everything.

2. A new, NFA engine that works much faster on some patterns, possibly slower

    on some patterns.

E1281

  Vim will automatically select the right engine for you. However, if you run
  into a problem or want to specifically select one engine or the other, you can
  prepend one of the following to the pattern:

```
      \%#=0   Force automatic selection.  Only has an effect when
              'regexpengine' has been set to a non-zero value.
      \%#=1   Force using the old engine.
      \%#=2   Force using the NFA engine.
```

You can also use the 'regexpengine' option to change the default.

E864 E868 E874 E875 E876 E877 E878

If selecting the NFA engine and it runs into something that is not implemented
the pattern will not match. This is only useful when debugging Vim.

3. Magic /magic

Some characters in the pattern, such as letters, are taken literally. They
match exactly the same character in the text. When preceded with a backslash
however, these characters may get a special meaning. For example, "a" matches
the letter "a", while "\a" matches any alphabetic character.

Other characters have a special meaning without a backslash. They need to be
preceded with a backslash to match literally. For example "." matches any
character while "\." matches a dot.

If a character is taken literally or not depends on the 'magic' option and the items in the pattern mentioned next. The 'magic' option should always be set. We mention the effect of 'nomagic' here for completeness, but we recommend against using that.

/\m /\M

Use of "\m" makes the pattern after it be interpreted as if 'magic' is set, ignoring the actual value of the 'magic' option.
Use of "\M" makes the pattern after it be interpreted as if 'nomagic' is used.

/\v /\V

Use of "\v" means that after it, all ASCII characters except '0'-'9', 'a'-'z', 'A'-'Z' and '_' have special meaning: "very magic"

Use of "\V" means that after it, only a backslash and the terminating character (usually / or ?) have special meaning: "very nomagic"

Examples:

after:	\v	\m 'magic'	\M 'nomagic'	\V	matches
	a	a	a	a	literal 'a'
	\a	\a	\a	\a	any alphabetic character
	.	.	\.	\.	any character
	\.	\.	.	.	literal dot
	$	$	$	\$	end-of-line
	*	*	*	*	any number of the previous atom
	~	~	\~	\~	latest substitute string
	()	\(\)	\(\)	\(\)	group as an atom
	|	|	|	|	nothing: separates alternatives
	\\	\\	\\	\\	literal backslash
	\{	{	{	{	literal curly brace

If you want to you can make a pattern immune to the 'magic' option being set or not by putting "\m" or "\M" at the start of the pattern.

4. Overview of pattern items pattern-overview

E865 E866 E867 E869

Overview of multi items. /multi E61 E62
More explanation and examples below, follow the links. E64 E871

multi 'magic'	'nomagic'		matches of the preceding atom	
/star	*	*	0 or more	as many as possible
/\+	\+	\+	1 or more	as many as possible
/\=	\=	\=	0 or 1	as many as possible
/\?	\?	\?	0 or 1	as many as possible
/\{	\{n,m}	\{n,m}	n to m	as many as possible
	\{n}	\{n}	n	exactly
	\{n,}	\{n,}	at least n	as many as possible
	\{,m}	\{,m}	0 to m	as many as possible
	\{}	\{}	0 or more	as many as possible (same as "*")
/\{-	\{-n,m}	\{-n,m}	n to m	as few as possible
	\{-n}	\{-n}	n	exactly
	\{-n,}	\{-n,}	at least n	as few as possible
	\{-,m}	\{-,m}	0 to m	as few as possible
	\{-}	\{-}	0 or more	as few as possible

E59

/\@>	\@>	\@>	1, like matching a whole pattern
/\@=	\@=	\@=	nothing, requires a match /zero-width
/\@!	\@!	\@!	nothing, requires NO match /zero-width
/\@<=	\@<=	\@<=	nothing, requires a match behind /zero-width
/\@<!	\@<!	\@<!	nothing, requires NO match behind /zero-width

Overview of ordinary atoms. /ordinary-atom

More explanation and examples below, follow the links.

ordinary atom magic	nomagic	matches	
/^	^	^	start-of-line (at start of pattern) /zero-width
/\^	\^	\^	literal '^'
/_^	_^	_^	start-of-line (used anywhere) /zero-width
/$	$	$	end-of-line (at end of pattern) /zero-width
/\$	\$	\$	literal '$'
/_$	_$	_$	end-of-line (used anywhere) /zero-width
/.	.	\.	any single character (not an end-of-line)
/_.	_.	_.	any single character or end-of-line
/\<	\<	\<	beginning of a word /zero-width
/\>	\>	\>	end of a word /zero-width
/\zs	\zs	\zs	anything, sets start of match
/\ze	\ze	\ze	anything, sets end of match
/\%^	\%^	\%^	beginning of file /zero-width E71
/\%$	\%$	\%$	end of file /zero-width
/\%V	\%V	\%V	inside Visual area /zero-width
/\%#	\%#	\%#	cursor position /zero-width
/\%'m	\%'m	\%'m	mark m position /zero-width
/\%l	\%23l	\%23l	in line 23 /zero-width
/\%c	\%23c	\%23c	in column 23 /zero-width
/\%v	\%23v	\%23v	in virtual column 23 /zero-width

Character classes: /character-classes

magic	nomagic	matches	
/\i	\i	\i	identifier character (see 'isident' option)
/\I	\I	\I	like "\i", but excluding digits
/\k	\k	\k	keyword character (see 'iskeyword' option)
/\K	\K	\K	like "\k", but excluding digits
/\f	\f	\f	file name character (see 'isfname' option)
/\F	\F	\F	like "\f", but excluding digits
/\p	\p	\p	printable character
/\P	\P	\P	like "\p", but excluding digits
/\s	\s	\s	whitespace character: <Space> and <Tab>
/\S	\S	\S	non-whitespace character; opposite of \s
/\d	\d	\d	digit: [0-9]
/\D	\D	\D	non-digit: [^0-9]
/\x	\x	\x	hex digit: [0-9A-Fa-f]
/\X	\X	\X	non-hex digit: [^0-9A-Fa-f]
/\o	\o	\o	octal digit: [0-7]
/\O	\O	\O	non-octal digit: [^0-7]
/\w	\w	\w	word character: [0-9A-Za-z_]
/\W	\W	\W	non-word character: [^0-9A-Za-z_]
/\h	\h	\h	head of word character: [A-Za-z_]
/\H	\H	\H	non-head of word character: [^A-Za-z_]
/\a	\a	\a	alphabetic character: [A-Za-z]
/\A	\A	\A	non-alphabetic character: [^A-Za-z]
/\l	\l	\l	lowercase character: [a-z]
/\L	\L	\L	non-lowercase character: [^a-z]
/\u	\u	\u	uppercase character: [A-Z]
/\U	\U	\U	non-uppercase character [^A-Z]
/_	_x	_x	where x is any of the characters above: character class with end-of-line included

(end of character classes)

magic	nomagic	matches		
/\e		\e	\e	<Esc>
/\t		\t	\t	<Tab>
/\r		\r	\r	<CR>
/\b		\b	\b	<BS>
/\n		\n	\n	end-of-line
/~		~	\~	last given substitute string
/\1		\1	\1	same string as matched by first \(\)
/\2		\2	\2	Like "\1", but uses second \(\) ...
/\9		\9	\9	Like "\1", but uses ninth \(\) E68
/\z1		\z1	\z1	only for syntax highlighting, see :syn-ext-match ...
/\z1		\z9	\z9	only for syntax highlighting, see :syn-ext-match

	x	x	a character with no special meaning matches itself
/[]	[]	\[]	any character specified inside the []
/\%[]	\%[]	\%[]	a sequence of optionally matched atoms
/\c	\c	\c	ignore case, do not use the 'ignorecase' option
/\C	\C	\C	match case, do not use the 'ignorecase' option
/\Z	\Z	\Z	ignore differences in Unicode "combining characters". Useful when searching voweled Hebrew or Arabic text.

magic	nomagic	matches		
/\m		\m	\m	'magic' on for the following chars in the pattern
/\M		\M	\M	'magic' off for the following chars in the pattern
/\v		\v	\v	the following chars in the pattern are "very magic"
/\V		\V	\V	the following chars in the pattern are "very nomagic" /\%#= \%#=1 \%#=1 select regexp engine /zero-width

/\%d	\%d	\%d	match specified decimal character (eg \%d123)
/\%x	\%x	\%x	match specified hex character (eg \%x2a)
/\%o	\%o	\%o	match specified octal character (eg \%o040)
/\%u	\%u	\%u	match specified multibyte character (eg \%u20ac)
/\%U	\%U	\%U	match specified large multibyte character (eg \%U12345678)
/\%C	\%C	\%C	match any composing characters

Example	matches
\<\I\i*	or\<\h\w*\<[a-zA-Z_][a-zA-Z0-9_]* An identifier (e.g., in a C program).

\(\.$|\. \)	A period followed by <EOL> or a space.
[.!?][])"']*\($|[ ]\)	A search pattern that finds the end of a sentence, with almost the same definition as the ")" command.
cat\Z	Both "cat" and "càt" ("a" followed by 0x0300) Does not match "càt" (character 0x00e0), even though it may look the same.

5. Multi items

pattern-multi-items

An atom can be followed by an indication of how many times the atom can be matched and in what way. This is called a multi. See /multi for an overview.

/star /\star

```
*       (use \* when 'magic' is not set)
        Matches 0 or more of the preceding atom, as many as possible.
        Example  'nomagic'      matches

 a*         a\*          "", "a", "aa", "aaa", etc.
 .*         \.\*         anything, also an empty string, no end-of-line
 \_.*       \_.\*        everything up to the end of the buffer
 \_.*END    \_.\*END     everything up to and including the last "END"
                         in the buffer
```

Exception: When "*" is used at the start of the pattern or just after "^" it matches the star character.

Be aware that repeating "_." can match a lot of text and take a long time. For example, _.*END matches all text from the current position to the last occurrence of "END" in the file. Since the "*" will match as many as possible, this first skips over all lines until the end of the file and then tries matching "END", backing up one character at a time.

/\+

```
\+      Matches 1 or more of the preceding atom, as many as possible.
Example         matches
        ^.\+$           any non-empty line
        \s\+            white space of at least one character
```

/\=

```
\=      Matches 0 or 1 of the preceding atom, as many as possible.
Example         matches
        foo\=           "fo" and "foo"
```

/\?

```
\?      Just like \=.  Cannot be used when searching backwards with the "?"
        command.
```

/\{ E60 E554 E870

```
\{n,m}  Matches n to m of the preceding atom, as many as possible
\{n}    Matches n of the preceding atom
\{n,}   Matches at least n of the preceding atom, as many as possible
\{,m}   Matches 0 to m of the preceding atom, as many as possible
\{}     Matches 0 or more of the preceding atom, as many as possible (like "*")
```

/\{-

```
\{-n,m} matches n to m of the preceding atom, as few as possible
\{-n}   matches n of the preceding atom
\{-n,}  matches at least n of the preceding atom, as few as possible
\{-,m}  matches 0 to m of the preceding atom, as few as possible
\{-}    matches 0 or more of the preceding atom, as few as possible
```

n and m are positive decimal numbers or zero

non-greedy

If a "-" appears immediately after the "{", then a shortest match first algorithm is used (see example below). In particular, "\{-}" is the same as "*" but uses the shortest match first algorithm. BUT: A match that starts earlier is preferred over a shorter match: "a\{-}b" matches "aaab" in "xaaab".

Example	matches
ab\{2,3}c	"abbc" or "abbbc"
a\{5}	"aaaaa"
ab\{2,}c	"abbc", "abbbc", "abbbbc", etc.
ab\{,3}c	"ac", "abc", "abbc" or "abbbc"
a[bc]\{3}d	"abbbd", "abbcd", "acbcd", "acccd", etc.
a\(bc\)\{1,2}d	"abcd" or "abcbcd"
a[bc]\{-}[cd]	"abc" in "abcd"
a[bc]*[cd]	"abcd" in "abcd"

The } may optionally be preceded with a backslash: \{n,m\}.

/\@=

```
\@=     Matches the preceding atom with zero width.
        Like "(?=pattern)" in Perl.
Example                 matches
        foo\(bar\)\@=           "foo" in "foobar"
        foo\(bar\)\@=foo        nothing
```

/zero-width

When using "\@=" (or "^", "$", "\<", "\>") no characters are included in the match. These items are only used to check if a match can be

made. This can be tricky, because a match with following items will be done in the same position. The last example above will not match "foobarfoo", because it tries match "foo" in the same position where "bar" matched.

Note that using "\&" works the same as using "\@=": "foo\&.." is the same as "\(foo\)\@=..". But using "\&" is easier, you don't need the parentheses.

/\@!

\@! Matches with zero width if the preceding atom does NOT match at the current position. /zero-width
Like "(?!pattern)" in Perl.

Example	**matches**
foo\(bar\)\@!	any "foo" not followed by "bar"
a.\{-}p\@!	"a", "ap", "app", "appp", etc. not immediately followed by a "p"
if \(\(then\)\@!.\)*$	"if " not followed by "then"

Using "\@!" is tricky, because there are many places where a pattern does not match. a.*p\@! will match from an "a" to the end of the line, because .* can match all characters in the line and the "p" doesn't match at the end of the line. "a.\{-}p\@!" will match any "a", "ap", "app", etc. that isn't followed by a "p", because the "." can match a "p" and "p\@!" doesn't match after that.

You can't use "\@!" to look for a non-match before the matching position: "\(foo\)\@!bar" will match "bar" in "foobar", because at the position where "bar" matches, "foo" does not match. To avoid matching "foobar" you could use "\(foo\)\@!...bar", but that doesn't match a bar at the start of a line. Use "\(foo\)\@<!bar".

Useful example: to find "foo" in a line that does not contain "bar":

```
/^\%(.*bar\)\@!.*\zsfoo
```

This pattern first checks that there is not a single position in the line where "bar" matches. If .*bar matches somewhere the \@! will reject the pattern. When there is no match any "foo" will be found. The "\zs" is to have the match start just before "foo".

/\@<=

\@<= Matches with zero width if the preceding atom matches just before what follows. /zero-width
Like "(?<=pattern)" in Perl, but Vim allows non-fixed-width patterns.

Example	**matches**
\(an_s\+\)\@<=file	"file" after "an" and white space or an end-of-line

For speed it's often much better to avoid this multi. Try using "\zs" instead /\zs. To match the same as the above example:
```
an\_s\+\zsfile
```
At least set a limit for the look-behind, see below.

"\@<=" and "\@<!" check for matches just before what follows. Theoretically these matches could start anywhere before this position. But to limit the time needed, only the line where what follows matches is searched, and one line before that (if there is one). This should be sufficient to match most things and not be too slow.

In the old regexp engine the part of the pattern after "\@<=" and "\@<!" are checked for a match first, thus things like "\1" don't work to reference \(\) inside the preceding atom. It does work the other way around:

Bad example	**matches**
\%#=1\1\@<=,\([a-z]\+\)	",abc" in "abc,abc"

However, the new regexp engine works differently, it is better to not rely on this behavior, do not use \@<= if it can be avoided:

Example	**matches**
\([a-z]\+\)\zs,\1	",abc" in "abc,abc"

\@123<=
Like "\@<=" but only look back 123 bytes. This avoids trying lots of matches that are known to fail and make executing the pattern very slow. Example, check if there is a "<" just before "span":
```
/<\@1<=span
```
This will try matching "<" only one byte before "span", which is the only place that works anyway.
After crossing a line boundary, the limit is relative to the end of the line. Thus the characters at the start of the line with the match are not counted (this is just to keep it simple).
The number zero is the same as no limit.

/\@<!

\@<! Matches with zero width if the preceding atom does NOT match just before what follows. Thus this matches if there is no position in the current or previous line where the atom matches such that it ends just before what follows. /zero-width
Like "(?<!pattern)" in Perl, but Vim allows non-fixed-width patterns.
The match with the preceding atom is made to end just before the match with what follows, thus an atom that ends in .* will work.
Warning: This can be slow (because many positions need to be checked

for a match). Use a limit if you can, see below.
Example matches

```
\(foo\)\@<!bar          any "bar" that's not in "foobar"
\(\/\/.*\)\@<!in        "in" which is not after "//"
```

\@123<!
Like "\@<!" but only look back 123 bytes. This avoids trying lots of matches that are known to fail and make executing the pattern very slow.

/\@>

\@> Matches the preceding atom like matching a whole pattern.
Like "(?>pattern)" in Perl.

Example	matches
\(a*\)\@>a	nothing (the "a*" takes all the "a"'s, there can't be another one following)

This matches the preceding atom as if it was a pattern by itself. If it doesn't match, there is no retry with shorter sub-matches or anything. Observe this difference: "a*b" and "a*ab" both match "aaab", but in the second case the "a*" matches only the first two "a"s. "\(a*\)\@>ab" will not match "aaab", because the "a*" matches the "aaa" (as many "a"s as possible), thus the "ab" can't match.

6. Ordinary atoms pattern-atoms

An ordinary atom can be:

/^

^ At beginning of pattern or after "\|", "\(", "\%(" or "\n": matches start-of-line; at other positions, matches literal '^'. /zero-width

Example	matches
^beep(	the start of the C function "beep" (probably).

/\^

\^ Matches literal '^'. Can be used at any position in the pattern, but not inside [].

/_^

_^ Matches start-of-line. /zero-width Can be used at any position in the pattern, but not inside [].

Example	matches
_s*_^foo	white space and blank lines and then "foo" at start-of-line

/$

$ At end of pattern or in front of "\|", "\)" or "\n" ('magic' on): matches end-of-line <EOL>; at other positions, matches literal '$'.
/zero-width

/\$

\$ Matches literal '$'. Can be used at any position in the pattern, but not inside [].

/_$

$ Matches end-of-line. /zero-width Can be used at any position in the pattern, but not inside []. Note that "a$b" never matches, since "b" cannot match an end-of-line. Use "a\nb" instead /\n.

Example	matches
foo_$_s*	"foo" at end-of-line and following white space and blank lines

. (with 'nomagic': \.) /. /\.
Matches any single character, but not an end-of-line.

/_.

_. Matches any single character or end-of-line.
Careful: _.* matches all text to the end of the buffer!

/\<

\< Matches the beginning of a word: The next char is the first char of a word. The 'iskeyword' option specifies what is a word character.
/zero-width

/\>

\> Matches the end of a word: The previous char is the last char of a word. The 'iskeyword' option specifies what is a word character.
/zero-width

/\zs

\zs Matches at any position, but not inside [], and sets the start of the match there: The next char is the first char of the whole match.
/zero-width
Example:

```
/^\s*\zsif
```

matches an "if" at the start of a line, ignoring white space.
Can be used multiple times, the last one encountered in a matching
branch is used. Example:

```
/\(.\{-}\zsFab\)\{3}
```

Finds the third occurrence of "Fab".
This cannot be followed by a multi. E888

/\ze

\ze Matches at any position, but not inside [], and sets the end of the match there: The previous char is the last char of the whole match. /zero-width
Can be used multiple times, the last one encountered in a matching branch is used.
Example: "end\ze\(if\|for\)" matches the "end" in "endif" and "endfor".
This cannot be followed by a multi. E888

/\%^ start-of-file

\%^ Matches start of the file. When matching with a string, matches the start of the string.
For example, to find the first "VIM" in a file:

```
/\%^\_.\{-}\zsVIM
```

/\%$ end-of-file

\%$ Matches end of the file. When matching with a string, matches the end of the string.
Note that this does NOT find the last "VIM" in a file:

```
/VIM\_.\{-}\%$
```

It will find the next VIM, because the part after it will always match. This one will find the last "VIM" in the file:

```
/VIM\ze\(\(VIM\)\@!\_.\)*\%$
```

This uses /\@! to ascertain that "VIM" does NOT match in any position after the first "VIM".
Searching from the end of the file backwards is easier!

/\%V

\%V Match inside the Visual area. When Visual mode has already been stopped match in the area that gv would reselect.
This is a /zero-width match. To make sure the whole pattern is inside the Visual area put it at the start and just before the end of the pattern, e.g.:

```
/\%Vfoo.*ba\%Vr
```

This also works if only "foo bar" was Visually selected. This:

```
/\%Vfoo.*bar\%V
```

would match "foo bar" if the Visual selection continues after the "r".
Only works for the current buffer.

/\%# cursor-position

\%# Matches with the cursor position. Only works when matching in a buffer displayed in a window.
WARNING: When the cursor is moved after the pattern was used, the result becomes invalid. Vim doesn't automatically update the matches.
This is especially relevant for syntax highlighting and 'hlsearch'.
In other words: When the cursor moves the display isn't updated for this change. An update is done for lines which are changed (the whole line is updated) or when using the CTRL-L command (the whole screen is updated). Example, to highlight the word under the cursor:

```
/\k*\%#\k*
```

When 'hlsearch' is set and you move the cursor around and make changes this will clearly show when the match is updated or not.

/\%'m /\%<'m /\%>'m

\%'m Matches with the position of mark m.
\%<'m Matches before the position of mark m.
\%>'m Matches after the position of mark m.
Example, to highlight the text from mark 's to 'e:

```
/.\%>'s.*\%<'e..
```

Note that two dots are required to include mark 'e in the match. That is because "\%<'e" matches at the character before the 'e mark, and since it's a /zero-width match it doesn't include that character.
WARNING: When the mark is moved after the pattern was used, the result becomes invalid. Vim doesn't automatically update the matches.
Similar to moving the cursor for "\%#" /\%#.

/\%l /\%>l /\%<l E951 E1204 E1273

\%23l   Matches in a specific line.
\%<23l Matches above a specific line (lower line number).
\%>23l Matches below a specific line (higher line number).
\%.l   Matches at the cursor line.
\%<.l   Matches above the cursor line.
\%>.l   Matches below the cursor line.
These six can be used to match specific lines in a buffer. The "23" can be any line number. The first line is 1.
WARNING: When inserting or deleting lines Vim does not automatically update the matches. This means Syntax highlighting quickly becomes wrong. Also when referring to the cursor position (".") and the cursor moves the display isn't updated for this change. An update is done when using the CTRL-L command (the whole screen is updated).
Example, to highlight the line where the cursor currently is:

```
:exe '/\%' .. line(".") .. 'l'
```

Alternatively use:

```
/\%.l
```

When 'hlsearch' is set and you move the cursor around and make changes this will clearly show when the match is updated or not.

/\%c /\%>c /\%<c

\%23c   Matches in a specific column.
\%<23c Matches before a specific column.
\%>23c Matches after a specific column.
\%.c   Matches at the cursor column.
\%<.c   Matches before the cursor column.
\%>.c   Matches after the cursor column.
These six can be used to match specific columns in a buffer or string. The "23" can be any column number. The first column is 1. Actually, the column is the byte number (thus it's not exactly right for multibyte characters).
WARNING: When inserting or deleting text Vim does not automatically update the matches. This means Syntax highlighting quickly becomes wrong. Also when referring to the cursor position (".") and the cursor moves the display isn't updated for this change. An update is done when using the CTRL-L command (the whole screen is updated).
Example, to highlight the column where the cursor currently is:

```
:exe '/\%' .. col(".") .. 'c'
```

Alternatively use:

```
/\%.c
```

When 'hlsearch' is set and you move the cursor around and make changes this will clearly show when the match is updated or not.
Example for matching a single byte in column 44:

```
/\%>43c.\%<46c
```

Note that "\%<46c" matches in column 45 when the "." matches a byte in column 44.

/\%v /\%>v /\%<v

\%23v   Matches in a specific virtual column.
\%<23v Matches before a specific virtual column.
\%>23v Matches after a specific virtual column.
\%.v   Matches at the current virtual column.
\%<.v   Matches before the current virtual column.
\%>.v   Matches after the current virtual column.
These six can be used to match specific virtual columns in a buffer or string. When not matching with a buffer in a window, the option values of the current window are used (e.g., 'tabstop').
The "23" can be any column number. The first column is 1.
Note that some virtual column positions will never match, because they are halfway through a tab or other character that occupies more than one screen character.
WARNING: When inserting or deleting text Vim does not automatically update highlighted matches. This means Syntax highlighting quickly becomes wrong. Also when referring to the cursor position (".") and the cursor moves the display isn't updated for this change. An update is done when using the CTRL-L command (the whole screen is updated).
Example, to highlight all the characters after virtual column 72:

```
/\%>72v.*
```

When 'hlsearch' is set and you move the cursor around and make changes this will clearly show when the match is updated or not.
To match the text up to column 17:

```
/^.*\%17v
```

To match all characters after the current virtual column (where the cursor is):

```
/\%>.v.*
```

Column 17 is not included, because this is a /zero-width match. To include the column use:

```
/^.*\%17v.
```

This command does the same thing, but also matches when there is no character in column 17:

```
/^.*\%<18v.
```

Note that without the "^" to anchor the match in the first column, this will also highlight column 17:

```
/.*\%17v
```

Column 17 is highlighted by 'hlsearch' because there is another match where .* matches zero characters.

Character classes:

\i	identifier character (see 'isident' option)	/\i
\I	like "\i", but excluding digits	/\I
\k	keyword character (see 'iskeyword' option)	/\k
\K	like "\k", but excluding digits	/\K
\f	file name character (see 'isfname' option)	/\f
\F	like "\f", but excluding digits	/\F
\p	printable character	/\p
\P	like "\p", but excluding digits	/\P

NOTE: the above also work for multibyte characters. The ones below only match ASCII characters, as indicated by the range.

whitespace white-space

\s	whitespace character: <Space> and <Tab>		/\s
\S	non-whitespace character; opposite of \s		/\S
\d	digit:	[0-9]	/\d
\D	non-digit:	[^0-9]	/\D
\x	hex digit:	[0-9A-Fa-f]	/\x
\X	non-hex digit:	[^0-9A-Fa-f]	/\X
\o	octal digit:	[0-7]	/\o
\O	non-octal digit:	[^0-7]	/\O
\w	word character:	[0-9A-Za-z_]	/\w
\W	non-word character:	[^0-9A-Za-z_]	/\W
\h	head of word character:	[A-Za-z_]	/\h
\H	non-head of word character:	[^A-Za-z_]	/\H
\a	alphabetic character:	[A-Za-z]	/\a
\A	non-alphabetic character:	[^A-Za-z]	/\A
\l	lowercase character:	[a-z]	/\l
\L	non-lowercase character:	[^a-z]	/\L
\u	uppercase character:	[A-Z]	/\u
\U	non-uppercase character:	[^A-Z]	/\U

NOTE: Using the atom is faster than the [] form.

NOTE: 'ignorecase', "\c" and "\C" are not used by character classes.

/_ E63 /_i /_I /_k /_K /_f /_F
/_p /_P /_s /_S /_d /_D /_x /_X
/_o /_O /_w /_W /_h /_H /_a /_A
/_l /_L /_u /_U

_x Where "x" is any of the characters above: The character class with end-of-line added

(end of character classes)

\e	matches <Esc>	/\e
\t	matches <Tab>	/\t
\r	matches <CR>	/\r
\b	matches <BS>	/\b
\n	matches an end-of-line	/\n

When matching in a string instead of buffer text a literal newline character is matched.

~	matches the last given substitute string	/~ /\~

\(\) A pattern enclosed by escaped parentheses. /\(/\(\) /\)
E.g., "\(^a\)" matches 'a' at the start of a line.
There can only be nine of these. You can use "\%(" to add more, but not counting it as a sub-expression.
E51 E54 E55 E872 E873

\1	Matches the same string that was matched by	/\1 E65
	the first sub-expression in \(and \).
	Example: "\([a-z]\).\1" matches "ata", "ehe", "tot", etc.
\2	Like "\1", but uses second sub-expression,	/\2
...	/\3

\9	Like "\1", but uses ninth sub-expression.	/\9
	Note: The numbering of groups is done based on which "\(" comes first
	in the pattern (going left to right), NOT based on what is matched
	first.

\%(\)	A pattern enclosed by escaped parentheses.	/\%(\) /\%(E53
	Just like \(\), but without counting it as a sub-expression. This
	allows using more groups and it's a little bit faster.

x	A single character, with no special meaning, matches itself
	/\ /\\

\x	A backslash followed by a single character, with no special meaning,
	is reserved for future expansions

[]	(with 'nomagic': \[])	/[] /\[] /_[] /collection E76
_[]
	A collection. This is a sequence of characters enclosed in square
	brackets. It matches any single character in the collection.

Example	**matches**
	[xyz]	any 'x', 'y' or 'z'
	[a-zA-Z]$	any alphabetic character at the end of a line
	\c[a-z]$	same
	[A-яЁё]	Russian alphabet (with utf-8 and cp1251)

/[\n]

	With "_" prepended the collection also includes the end-of-line.
	The same can be done by including "\n" in the collection. The
	end-of-line is also matched when the collection starts with "^"! Thus
	"_[^ab]" matches the end-of-line and any character but "a" and "b".
	This makes it Vi compatible: Without the "_" or "\n" the collection
	does not match an end-of-line.

E769

	When the ']' is not there Vim will not give an error message but
	assume no collection is used. Useful to search for '['. However, you
	do get E769 for internal searching. And be aware that in a
	:substitute command the whole command becomes the pattern. E.g.
	":s/[/x/" searches for "[/x" and replaces it with nothing. It does
	not search for "[" and replaces it with "x"!

E944 E945

	If the sequence begins with "^", it matches any single character NOT
	in the collection: "[^xyz]" matches anything but 'x', 'y' and 'z'.

- If two characters in the sequence are separated by '-', this is

	shorthand for the full list of ASCII characters between them. E.g.,
	"[0-9]" matches any decimal digit. If the starting character
	exceeds the ending character, e.g. [c-a], E944 occurs. Non-ASCII
	characters can be used, but the character values must not be more
	than 256 apart in the old regexp engine. For example, searching by
	[\u3000-\u4000] after setting re=1 emits a E945 error. Prepending
	\%#=2 will fix it.

- A character class expression is evaluated to the set of characters

	belonging to that character class. The following character classes
	are supported:

	Name	Func	Contents ~
[:alnum:]	[:alnum:]	isalnum	ASCII letters and digits
[:alpha:]	[:alpha:]	isalpha	ASCII letters
[:blank:]	[:blank:]		space and tab
[:cntrl:]	[:cntrl:]	iscntrl	ASCII control characters
[:digit:]	[:digit:]		decimal digits '0' to '9'
[:graph:]	[:graph:]	isgraph	ASCII printable characters excluding space
[:lower:]	[:lower:]	(1)	lowercase letters (all letters when 'ignorecase' is used and the old engine is in use two-engines)
[:print:]	[:print:]	(2)	printable characters including space
[:punct:]	[:punct:]	ispunct	ASCII punctuation characters
[:space:]	[:space:]		whitespace characters: space, tab, CR, NL, vertical tab, form feed
[:upper:]	[:upper:]	(3)	uppercase letters (all letters when 'ignorecase' is used and the old engine is in use two-engines)
[:xdigit:]	[:xdigit:]		hexadecimal digits: 0-9, a-f, A-F
[:return:]	[:return:]		the <CR> character
[:tab:]	[:tab:]		the <Tab> character
[:escape:]	[:escape:]		the <Esc> character
[:backspace:]	[:backspace:]		the <BS> character
[:ident:]	[:ident:]		identifier character (same as "\i")
[:keyword:]	[:keyword:]		keyword character (same as "\k")
[:fname:]	[:fname:]		file name character (same as "\f")

	The square brackets in character class expressions are additional to

the square brackets delimiting a collection. For example, the following is a plausible pattern for a UNIX filename: "[-./[:alnum:]_~]\+". That is, a list of at least one character, each of which is either '-', '.', '/', alphabetic, numeric, '_' or '~'.
These items only work for 8-bit characters, except [:lower:] and [:upper:] also work for multibyte characters when using the new regexp engine. See two-engines. In the future these items may work for multibyte characters. For now, to get all "alpha" characters you can use: [[:lower:][:upper:]].

The "Func" column shows what library function is used. The implementation depends on the system. Otherwise:
(1) Uses islower() for ASCII and Vim builtin rules for other characters.
(2) Uses Vim builtin rules
(3) As with (1) but using isupper()

/[[= [==]

- An equivalence class. This means that characters are matched that

have almost the same meaning, e.g., when ignoring accents. This only works for Unicode, latin1 and latin9. The form is:
[=a=]

/[[. [..]

- A collation element. This currently simply accepts a single

character in the form:
[.a.]

/\]

- To include a literal ']', '^', '-' or '\' in the collection, put a

backslash before it: "[xyz\]]", "[\^xyz]", "[xy\-z]" and "[xyz\\]". (**Note:** POSIX does not support the use of a backslash this way). For ']' you can also make it the first character (following a possible "^"): "[]xyz]" or "[^]xyz]".
For '-' you can also make it the first or last character: "[-xyz]", "[^-xyz]" or "[xyz-]". For '\' you can also let it be followed by any character that's not in "^]-\bdertnoUux". "[\xyz]" matches '\', 'x', 'y' and 'z'. It's better to use "\\" though, future expansions may use other characters after '\'.
- Omitting the trailing] is not considered an error. "[]" works like

"[]]", it matches the ']' character.
- The following translations are accepted when the 'l' flag is not

included in 'cpoptions':
\e <Esc>
\t <Tab>
\r <CR> (NOT end-of-line!)
\b <BS>
\n line break, see above /[\n]
\d123 decimal number of character
\o40 octal number of character up to 0o377
\x20 hexadecimal number of character up to 0xff
\u20AC hex. number of multibyte character up to 0xffff
\U1234 hex. number of multibyte character up to 8 characters
0xffffffff E1541
NOTE: The other backslash codes mentioned above do not work inside []!
- Matching with a collection can be slow, because each character in

the text has to be compared with each character in the collection. Use one of the other atoms above when possible. Example: "\d" is much faster than "[0-9]" and matches the same characters. However, the new NFA regexp engine deals with this better than the old one.

/\%[] E69 E70 E369

\%[] A sequence of optionally matched atoms. This always matches.
It matches as much of the list of atoms it contains as possible. Thus it stops at the first atom that doesn't match. For example:

```
/r\%[ead]
```

matches "r", "re", "rea" or "read". The longest that matches is used.
To match the Ex command "function", where "fu" is required and "nction" is optional, this would work:

```
/\<fu\%[nction]\>
```

The end-of-word atom "\>" is used to avoid matching "fu" in "full".
It gets more complicated when the atoms are not ordinary characters.
You don't often have to use it, but it is possible. Example:

```
/\<r\%[[eo]ad]\>
```

Matches the words "r", "re", "ro", "rea", "roa", "read" and "road".
There can be no \(\), \%(\) or \z(\) items inside the [] and \%[] does
not nest.
To include a "[" use "[[]" and for "]" use []]", e.g.,:

```
/index\%[[[]0[]]]
```

matches "index" "index[", "index[0" and "index[0]".

/\%d /\%x /\%o /\%u /\%U E678

\%d123 Matches the character specified with a decimal number. Must be
followed by a non-digit.
\%o40 Matches the character specified with an octal number up to 0o377.
Numbers below 0o40 must be followed by a non-octal digit or a
non-digit.
\%x2a Matches the character specified with up to two hexadecimal characters.
\%u20AC Matches the character specified with up to four hexadecimal
characters.
\%U1234abcd Matches the character specified with up to eight hexadecimal
characters, up to 0x7fffffff (the maximum allowed value is INT_MAX
E1541, but the maximum valid Unicode codepoint is U+10FFFF).

7. Ignoring case in a pattern /ignorecase

If the 'ignorecase' option is on, the case of normal letters is ignored.
'smartcase' can be set to ignore case when the pattern contains lowercase
letters only.

/\c /\C

When "\c" appears anywhere in the pattern, the whole pattern is handled like
'ignorecase' is on. The actual value of 'ignorecase' and 'smartcase' is
ignored. "\C" does the opposite: Force matching case for the whole pattern.
Note that 'ignorecase', "\c" and "\C" are not used for the character classes.

Examples:

pattern	'ignorecase'	'smartcase'	matches
foo	off	-	foo
foo	on	-	foo Foo FOO
Foo	on	off	foo Foo FOO
Foo	on	on	Foo
\cfoo	-	-	foo Foo FOO
foo\C	-	-	foo

Technical detail: NL-used-for-Nul

<Nul> characters in the file are stored as <NL> in memory. In the display
they are shown as "^@". The translation is done when reading and writing
files. To match a <Nul> with a search pattern you can just enter CTRL-@ or
"CTRL-V 000". This is probably just what you expect. Internally the
character is replaced with a <NL> in the search pattern. What is unusual is
that typing CTRL-V CTRL-J also inserts a <NL>, thus also searches for a <Nul>
in the file.

CR-used-for-NL

When 'fileformat' is "mac", <NL> characters in the file are stored as <CR>
characters internally. In the text they are shown as "^J". Otherwise this
works similar to the usage of <NL> for a <Nul>.

When working with expression evaluation, a <NL> character in the pattern
matches a <NL> in the string. The use of "\n" (backslash n) to match a <NL>
doesn't work there, it only works to match text in the buffer.

pattern-multi-byte pattern-multibyte

Patterns will also work with multibyte characters, mostly as you would
expect. But invalid bytes may cause trouble, a pattern with an invalid byte
will probably never match.

8. Composing characters patterns-composing

/\Z

When "\Z" appears anywhere in the pattern, all composing characters are
ignored. Thus only the base characters need to match, the composing
characters may be different and the number of composing characters may differ.
Exception: If the pattern starts with one or more composing characters, these
must match.

/\%C

Use "\%C" to skip any composing characters. For example, the pattern "a" does
not match in "càt" (where the a has the composing character 0x0300), but
"a\%C" does. Note that this does not match "cát" (where the á is character
0xe1, it does not have a compositing character). It does match "cat" (where
the a is just an a).

When a composing character appears at the start of the pattern or after an
item that doesn't include the composing character, a match is found at any
character that includes this composing character.

When using a dot and a composing character, this works the same as the
composing character by itself, except that it doesn't matter what comes before
this.

The order of composing characters does not matter. Also, the text may have more composing characters than the pattern, it still matches. But all composing characters in the pattern must be found in the text.

Suppose B is a base character and x and y are composing characters:

pattern	text	match
Bxy	Bxy	yes (perfect match)
Bxy	Byx	yes (order ignored)
Bxy	By	no (x missing)
Bxy	Bx	no (y missing)
Bx	Bx	yes (perfect match)
Bx	By	no (x missing)
Bx	Bxy	yes (extra y ignored)
Bx	Byx	yes (extra y ignored)

9. Compare with Perl patterns

perl-patterns

Vim's regexes are most similar to Perl's, in terms of what you can do. The difference between them is mostly just notation; here's a summary of where they differ:

Capability	in Vimspeak	in Perlspeak
force case insensitivity	\c	(?i)
force case sensitivity	\C	(?-i)
backref-less grouping	\%(atom\)	(?:atom)
conservative quantifiers	\{-n,m}	*?, +?, ??, {}?
0-width match	atom\@=	(?=atom)
0-width non-match	atom\@!	(?!atom)
0-width preceding match	atom\@<=	(?<=atom)
0-width preceding non-match	atom\@<!	(?<!atom)
match without retry	atom\@>	(?>atom)

Vim and Perl handle newline characters inside a string a bit differently:

In Perl, ^ and $ only match at the very beginning and end of the text, by default, but you can set the 'm' flag, which lets them match at embedded newlines as well. You can also set the 's' flag, which causes a . to match newlines as well. (Both these flags can be changed inside a pattern using the same syntax used for the i flag above, BTW.)

On the other hand, Vim's ^ and $ always match at embedded newlines, and you get two separate atoms, \%^ and \%$, which only match at the very start and end of the text, respectively. Vim solves the second problem by giving you the _ "modifier": put it in front of a . or a character class, and they will match newlines as well.

Finally, these constructs are unique to Perl:

- execution of arbitrary code in the regex: (?{perl code})
- conditional expressions: (?(condition)true-expr|false-expr)

...and these are unique to Vim:

- changing the magic-ness of a pattern: \v \V \m \M

  (very useful for avoiding backslashitis)
- sequence of optionally matching atoms: \%[atoms]
- \& (which is to \| what "and" is to "or"; it forces several branches

  to match at one spot)
- matching lines/columns by number: \%5l \%5c \%5v
- setting the start and end of the match: \zs \ze

10. Highlighting matches

match-highlight

syntax-vs-match

Note that the match highlight mechanism is independent of syntax-highlighting, which is (usually) a buffer-local highlighting, while matching is window-local, both methods can be freely mixed. Match highlighting functions give you a bit more flexibility in when and how to apply, but are typically only used for temporary highlighting, without strict rules. Both methods can be used to conceal text.

Thus the matching functions like matchadd() won't consider syntax rules and functions like synconcealed() and the other way around.

:mat :match

:mat[ch] {group} /{pattern}/
Define a pattern to highlight in the current window. It will be highlighted with {group}. Example:

```
:highlight MyGroup ctermbg=green guibg=green
:match MyGroup /TODO/
```

Instead of // any character can be used to mark the start and end of the {pattern}. Watch out for using special characters, such as '"' and '|'.

{group} must exist at the moment this command is executed.

The {group} highlighting still applies when a character is to be highlighted for 'hlsearch', as the highlighting for matches is given higher priority than that of 'hlsearch'. Syntax highlighting (see 'syntax') is also overruled by matches.

Note that highlighting the last used search pattern with 'hlsearch' is used in all windows, while the pattern defined with ":match" only exists in the current window. It is kept when switching to another buffer.

'ignorecase' does not apply, use /\c in the pattern to ignore case. Otherwise case is not ignored.

'redrawtime' defines the maximum time searched for pattern matches.

When matching end-of-line and Vim redraws only part of the display you may get unexpected results. That is because Vim looks for a match in the line where redrawing starts.

Also see matcharg() and getmatches(). The former returns the highlight group and pattern of a previous :match command. The latter returns a list with highlight groups and patterns defined by both matchadd() and :match.

Highlighting matches using :match are limited to three matches (aside from :match, :2match and :3match are available). matchadd() does not have this limitation and in addition makes it possible to prioritize matches.

Another example, which highlights all characters in virtual column 72 and more:

```
:highlight rightMargin term=bold ctermfg=blue guifg=blue
:match rightMargin /.\%>72v/
```

To highlight all character that are in virtual column 7:

```
:highlight col8 ctermbg=grey guibg=grey
:match col8 /\%<8v.\%>7v/
```

Note the use of two items to also match a character that occupies more than one virtual column, such as a TAB.

:mat[ch]
:mat[ch] none
Clear a previously defined match pattern.

:2mat[ch] {group} /{pattern}/ :2match

:2mat[ch]
:2mat[ch] none
:3mat[ch] {group} /{pattern}/ :3match

:3mat[ch]
:3mat[ch] none
Just like :match above, but set a separate match. Thus there can be three matches active at the same time. The match with the lowest number has priority if several match at the same position. It uses the match id 3.
The ":3match" command is used by (older Vims) matchparen plugin. You are suggested to use ":match" for manual matching and ":2match" for another plugin or even better make use of the more flexible matchadd() (and similar) functions instead.

11. Fuzzy matching fuzzy-matching

Fuzzy matching scores how well a string matches a pattern when the pattern characters appear in order but not necessarily contiguously.

Example:

```
Pattern:        "vim"
Candidates:     "vim"        -> perfect
            "vimeo"          -> good (v i m)
            "voice mail" -> weaker (v _ i _ _ _ m)
            "vintage"    -> no match (no "m")
```

If the search string has multiple words, each word is matched separately and may appear in any order in the candidate. For example "get pat" matches

"GetPattern", "PatternGet", "getPattern", "patGetter", "getSomePattern", "MatchpatternGet", etc.

The 'ignorecase' and 'smartcase' options do not apply, case is ignored if the pattern is all lower case.

Vim's implementation is based on the algorithm from the fzy project:
https://github.com/jhawthorn/fzy

It uses dynamic programming to compute an optimal score for a given pattern and candidate.

The algorithm works in two stages:

1. Forward pass

   Scan the candidate left to right, tracking the best score for each pattern position. Matches score higher when they occur at the start of the candidate, the start of a word (space, underscore, dash, camelCase), or directly after the previous match.
2. Backward pass

   Start from the best-scoring end position and step back to find match positions, ensuring the alignment is optimal.

Vim extends the original algorithm to support multibyte codepoints, allowing correct matching for UTF-8 and other encodings.

Time complexity is O(pattern * candidate). Memory usage is proportional to the same.

The matchfuzzy() and matchfuzzypos() functions perform fuzzy searching in a List of strings. matchfuzzy() returns the matching strings, while matchfuzzypos() returns the matches along with their positions and scores.

The "f" flag of :vimgrep enables fuzzy matching.

To enable fuzzy matching for ins-completion, add "fuzzy" to the 'completeopt' option. For cmdline-completion, add "fuzzy" to the 'wildoptions' option.

Editing compressed files with Vim bzip2 compress

1. Autocommands gzip-autocmd

The functionality mentioned here is a standard-plugin.
This plugin is only available if 'compatible' is not set.
You can avoid loading this plugin by setting the "loaded_gzip" variable:

```
:let loaded_gzip = 1
```

g:gzip_exec

For security reasons, one may prevent that Vim runs executables automatically
when opening a buffer. This option (default: "1") can be used to prevent
executing the executables command when set to "0":

```
:let g:gzip_exec = 0
```

1. Autocommands gzip-autocmd

The plugin installs autocommands to intercept reading and writing of files
with these extensions:

extension	compression
*.bz2	bzip2
*.bz3	bzip3
*.gz	gzip
*.lz	lzip
*.lz4	lz4
*.lzma	lzma
*.xz	xz
*.Z	compress (Lempel-Ziv)
*.zst	zstd

That's actually the only thing you need to know. There are no options.

After decompressing a file, the filetype will be detected again. This will
make a file like "foo.c.gz" get the "c" filetype.

If you have 'patchmode' set, it will be appended after the extension for
compression. Thus editing the patchmode file will not give you the automatic
decompression. You have to rename the file if you want this.

Msgpack.vim introduction

This plugin contains utility functions to be used in conjunction with
msgpackdump() and msgpackparse() functions.

Msgpack.vim manual

msgpack.vim-manual

FUNCTION ARGUMENTS

msgpack.vim-arguments

Disambiguation of arguments described below. **Note:** if e.g. function is listed
as accepting {msgpack-integer} (or anything else) it means that function
does not check whether argument matches its description.

{msgpack-value}	Either msgpack-special-dict or a regular value, but not function reference.
{msgpack-integer}	Any value for which msgpack#type() will return "integer".
{msgpack-special-int}	msgpack-special-dict representing integer.

msgpack#is_int({msgpack-value}) msgpack#is_int()

Returns 1 if given {msgpack-value} is integer value, 0 otherwise.

msgpack#is_uint({msgpack-value}) msgpack#is_uint()

Returns 1 if given {msgpack-value} is integer value greater or equal
to zero, 0 otherwise.

msgpack#strftime

msgpack#strftime({format}, {msgpack-integer}) msgpack#strftime()

Same as strftime(), but second argument may be
msgpack-special-dict. Requires Python to really work with
msgpack-special-dicts.

msgpack#strptime

msgpack#strptime({format}, {time}) msgpack#strptime()

Reverse of msgpack#strftime(): for any time and format
msgpack#equal(msgpack#strptime(format, msgpack#strftime(format,
time)), time) be true. Requires ||Python|, without it only supports
non-|msgpack-special-dict| nonnegative times and format equal to
%Y-%m-%dT%H:%M:%S.

msgpack#int_dict_to_str({msgpack-special-int}) msgpack#int_dict_to_str()
Function which converts msgpack-special-dict integer value to
a hexadecimal value like 0x1234567890ABCDEF (always returns exactly 16
hexadecimal digits).

msgpack#special_type({msgpack-value}) msgpack#special_type()

Returns zero if {msgpack-value} is not msgpack-special-dict. If it
is it returns name of the key in v:msgpack_types which represents
{msgpack-value} type.

msgpack#type({msgpack-value}) msgpack#type()

Returns name of the key in v:msgpack_types that represents
{msgpack-value} type. Never returns zero: this function returns
msgpack type which will be dumped by msgpackdump() should it receive
a list with single {msgpack-value} as input.

msgpack#deepcopy({msgpack-value}) msgpack#deepcopy()

Like deepcopy(), but works correctly with msgpack-special-dict
values. Plain deepcopy() will destroy all types in
msgpack-special-dict values because it will copy _TYPE key values,
while they should be preserved.

msgpack#string({msgpack-value}) msgpack#string()

Like string(), but saves information about msgpack types. Values
dumped by msgpack#string may be read back by msgpack#eval().
Returns is the following:

- Dictionaries are dumped as "{key1: value1, key2: value2}". **Note:**

  msgpack allows any values in keys, so with some
  msgpack-special-dict values msgpack#string() may produce even
  "{{1: 2}: 3, [4]: 5}".

- Lists are dumped as "[value1, value2]".
- Strings are dumped as

  1. "abc": binary string.
  2. ="abc": string.
  3. +(10)"ext": extension strings (10 may be replaced with any 8-bit signed integer).

  Inside strings the following escape sequences may be present: "\0" (represents NUL byte), "\n" (represents line feed) and "\"" (represents double quote).
- Floating-point and integer values are dumped using string() or msgpack#int_dict_to_str().
- Booleans are dumped as "TRUE" or "FALSE".
- Nil values are dumped as "NIL".

msgpack#eval({string}, {dict}) msgpack#eval()

Transforms string created by msgpack#string() into a value suitable for msgpackdump(). Second argument allows adding special values that start with head characters (/\h) and contain only word characters (/\w). Built-in special values are "TRUE", "FALSE", "NIL", "nan" and "inf" and they cannot be overridden. Map values are always evaluated to msgpack-special-dict values, as well as hexadecimal digits. When evaluating maps order of keys is preserved.

Note that in addition to regular integer representations that may be obtained using msgpack#string() msgpack#eval() also supports C-style “character” integer constants like '/' (equivalent to char2nr('/'): 47). This also allows '\0' (number is decimal).

msgpack#equal

msgpack#equal({msgpack-value}, {msgpack-value}) msgpack#equal()

Returns 1 if given values are equal, 0 otherwise. When comparing msgpack map values order of keys is ignored. Comparing msgpack-special-dict with equivalent non-special-dict value evaluates to 1.

Highlighting matching parens

The functionality mentioned here is a standard-plugin.
This plugin is only available if 'compatible' is not set.

You can avoid loading this plugin by setting the "loaded_matchparen" variable:

```
:let loaded_matchparen = 1
```

The plugin installs CursorMoved, CursorMovedI and WinEnter autocommands to
redefine the match highlighting.

:NoMatchParen :DoMatchParen

To disable the plugin after it was loaded use this command:

```
:NoMatchParen
```

And to enable it again:

```
:DoMatchParen
```

The highlighting used is MatchParen. You can specify different colors with
the ":highlight" command. Example:

```
:hi MatchParen ctermbg=blue guibg=lightblue
```

By default the plugin will highlight both the paren under the cursor and the
matching one using the hl-MatchParen highlighting group. This may result in
the cursor briefly disappearing from the screen as the MatchParen colors take
over the cursor highlight. To prevent this from happening and have the plugin
only highlight the matching paren and not the one under the cursor
(effectively leaving the cursor style unchanged), you can set the
"matchparen_disable_cursor_hl" variable:

```
:let matchparen_disable_cursor_hl = 1
```

The characters to be matched come from the 'matchpairs' option. You can
change the value to highlight different matches. Note that not everything is
possible. For example, you can't highlight single or double quotes, because
the start and end are equal.

The syntax highlighting attributes are used. When the cursor currently is not
in a string or comment syntax item, then matches inside string and comment
syntax items are ignored. Any syntax items with "string" or "comment"
somewhere in their name are considered string or comment items.

The search is limited to avoid a delay when moving the cursor. The limits
are:

- What is visible in the window.
- 100 lines above or below the cursor to avoid a long delay when there are closed folds.
- 'synmaxcol' times 2 bytes before or after the cursor to avoid a delay in a long line with syntax highlighting.
- A timeout of 300 msec (60 msec in Insert mode). This can be changed with the "g:matchparen_timeout" and "g:matchparen_insert_timeout" variables and their buffer-local equivalents "b:matchparen_timeout" and "b:matchparen_insert_timeout".

If you would like the % command to work better, the |matchit| plugin can be
used. This plugin also helps to skip matches in comments. This is unrelated
to the matchparen highlighting, they use a different mechanism.

by Gustavo Niemeyer

This is a filetype plugin to work with rpm spec files.

Currently, this Vim plugin allows you to easily update the %changelog section in RPM spec files. It will even create a section for you if it doesn't exist yet. If you've already inserted an entry today, it will give you the opportunity to just add a new item in today's entry. If you don't provide a format string (spec_chglog_format), it'll ask you an email address and build a format string by itself.

1. How to use it spec-how-to-use-it

2. Customizing spec-customizing

1. How to use it

The spec_chglog plugin provides a map like the following:

```
:map <buffer> <LocalLeader>c <Plug>SpecChangelog
```

It means that you may run the plugin inside a spec file by pressing your maplocalleader key (default is '\') plus 'c'. If you do not have spec_chglog_format set, the plugin will ask you for an email address to use in this edit session.

Every time you run the plugin, it will check to see if the last entry in the changelog has been written today and by you. If the entry matches, it will just insert a new changelog item, otherwise it will create a new changelog entry. If you are running with spec_chglog_release_info enabled, it will also check if the name, version and release matches. The plugin is smart enough to ask you if it should update the package release, if you have not done so.

Setting a map spec-setting-a-map

As you should know, you can easily set a map to access any Vim command (or anything, for that matter). If you don't like the default map of <LocalLeader>c, you may just set up your own key. The following line shows you how you could do this in your vimrc file, mapping the plugin to the <F5> key:

```
au FileType spec map <buffer> <F5> <Plug>SpecChangelog
```

Note: the plugin will respect your desire to change the default mapping and won't set it.

This command will add a map only in the spec file buffers.

2. Customizing spec-customizing

The format string spec_chglog_format

You can easily customize how your spec file entry will look like. To do this just set the variable "spec_chglog_format" in your vimrc file like this:

```
let spec_chglog_format = "%a %b %d %Y My Name <my@email.com>"
```

Note that "%a %b %d %Y" is the most used time format. If you don't provide a format string, when you run the SpecChangelog command for the first time, it will ask you an email address and build the spec_chglog_format variable for you. This way, you will only need to provide your email address once.

To discover which format options you can use, take a look at the strftime() function man page.

Where to insert new items spec_chglog_prepend

The plugin will usually insert new %changelog entry items (note that it's not the entry itself) after the existing ones. If you set the spec_chglog_prepend variable

```
let spec_chglog_prepend = 1
```

it will insert new items before the existing ones.

Inserting release info spec_chglog_release_info

If you want, the plugin may automatically insert release information on each changelog entry. One advantage of turning this feature on is that it may control if the release has been updated after the last change in the package or not. If you have not updated the package version or release, it will ask you if it should update the package release for you. To turn this feature on, just insert the following code in your vimrc:

```
let spec_chglog_release_info = 1
```

Then, the first item in your changelog entry will be something like:

```
+ name-1.0-1cl
```

If you don't like the release updating feature and don't want to answer
"No" each time it detects an old release, you may disable it with

```
let spec_chglog_never_increase_release = 1
```

Good luck!!

```

1. Contents

tar tar-contents

1. Contents.....tar-contents

2. Usage.....tar-usage

3. Options.....tar-options

4. History.....tar-history

2. Usage

tar-usage tar-manual

When one edits a *.tar file, this plugin will handle displaying a
contents page. Select a file to edit by moving the cursor atop
the desired file, then hit the <return> key. After editing, one may
also write to the file. Currently, one may not make a new file in
tar archives via the plugin.

:TarDiff

DIFFERENCING SUPPORT~

:TarDiff [filename]

This command will attempt to show the differences between the tarball
version of a file and the associated file on the system. In order to
find that file on the system, the script uses the path associated with
the file mentioned in the tarball. If the current directory is not
correct for that path, :TarDiff will fail to find the associated file.

If the [filename] is given, that filename (and path) will be used to
specify the associated file.

PREVENTING LOADING~

If for some reason you do not wish to use vim to examine tar'd files,
you may put the following two variables into your <.vimrc> to prevent
the tar plugin from loading:

```
let g:loaded_tarPlugin= 1
let g:loaded_tar      = 1
```

tar-mappings

MAPPINGS~

The following (buffer-local) mappings are available in a tar buffer:

<CR>	Open selected file for editing, any changes will be written back to the archive.
<LeftMouse>	same as <CR>
x	Extract selected file.

3. Options

tar-options

These options are variables that one may change, typically in one's
<.vimrc> file.

Variable	Default Value	Explanation
g:tar_browseoptions	"Ptf"	used to get a list of contents
g:tar_readoptions	"OPxf"	used to extract a file from a tarball
g:tar_cmd	"tar"	the name of the tar program
g:tar_nomax	0	if true, file window will not be maximized
g:tar_writeoptions	"uf"	used to update/replace a file

4. History

v31     Apr 02, 2017    * (klartext) reported that browsing encrypted
                          files in a zip archive created unencrypted
                          swap files.  I am applying a similar fix
                          used on zip.vim to tar.vim: new buffers
                          are opened with :noswapfile.
        May 16, 2017    * When the mouse option isn't empty, the
                          leftmouse can be used to select a file
                          in the tar-file listing.
v30     Apr 22, 2014    * .tgz files are ambiguous: they may have been
                          compressed with either gzip or bzip2.  Tar.vim
                          disambiguates by using unix's "file" command.
        Feb 18, 2016    * Changed =~ to =~# where appropriate
        Feb 18, 2017    * Now also permits xz decompression
v28     Jun 23, 2011    * a few more decompression options (tbz tb2 txz)
v27     May 31, 2011    * moved cygwin detection before g:tar_copycmd
                          handling
                        * inserted additional :keepj modifiers
                        * changed silent  to  sil!  (:silent)
v26     Aug 09, 2010    * uses buffer-local instead of window variables
                          to hold tarfile name
                        * inserted keepj before 0d to protect jump list
v25     Jun 19, 2010    * (Jan Steffens) added support for xz
                          compression
v24     Apr 07, 2009    * :Untarvim command implemented
        Sep 28, 2009    * Added lzma support
v22     Aug 08, 2008    * security fixes
v16     Jun 06, 2008    * tarfile:: used instead of tarfile: when
                          editing files inside tarballs.  Fixes a
                          problem with tarballs called things like
                          c:\abc.tar. (tnx to Bill McCarthy)
v14     May 09, 2008    * arno caught a security bug
        May 28, 2008    * various security improvements.  Now requires
                          patch 299 which provides the fnameescape()
                          function
        May 30, 2008    * allows one to view *.gz and *.bz2 files that
                          are in *.tar files.
v12     Sep 07, 2007    * &shq now used if not the empty string for
                          g:tar_shq
v10     May 02, 2006    * now using "redraw then echo" to show messages,
                          instead of "echo and prompt user"
v9      May 02, 2006    * improved detection of masquerading as tar file
v8      May 02, 2006    * allows editing of files that merely masquerade
                          as tar files
v7      Mar 22, 2006    * work on making tar plugin work across network
        Mar 27, 2006    * g:tar_cmd now available for users to change
                          the name of the tar program to be used.  By
                          default, of course, it's "tar".
v6      Dec 21, 2005    * writing to files not in directories caused
                          problems - fixed (pointed out by
                          Christian Robinson)
v5      Nov 22, 2005    * report option workaround installed
v3      Sep 16, 2005    * handles writing files in an archive back to
                          the archive
        Oct 18, 2005    * <amatch> used instead of <afile> in autocmds
        Oct 18, 2005    * handles writing to compressed archives
        Nov 03, 2005    * handles writing tarfiles across a network
                          using netrw#NetWrite()
v2                      * converted to use Vim7's new autoload feature
                          by Bram Moolenaar
v1      (original)      * Michael Toren
                          (see michael.toren.net/code/
                           link seems dead)
```

vim-tutor-mode provides a system to follow and create interactive tutorials
for vim and third party plugins. It replaces the venerable vimtutor system.

Original Author: Felipe Morales <https://github.com/fmoralesc>

1. Usage

vim-tutor-usage

vim-tutor-mode tutorials are hypertext documents, they have rich text and
contain links. To stand out from the rest of the text, links are underlined.
You can follow them by placing the cursor over them and pressing <Enter>, or
by double-clicking them.

1.1 Commands

:Tutor {tutorial}

Opens a tutorial. Command-line completion for {tutorial} is provided, the candidates are a list of '.tutor' files found in the 'tutor/' folder in the 'runtimepath'. Tutorials prefixed with 'vim-' will always be shown first.

If no {tutorial} is provided, the command starts the 'vim-01-beginner' tutorial, which is equivalent to Vim's vimtutor.

2. Creating tutorials

vim-tutor-create

Writing vim-tutor-mode tutorials is easy. For an overview of the format used,
please consult the 'tutor.tutor' file:

```
:Tutor tutor
```

New tutorials must be placed in the 'tutor/' folder in the 'runtimepath'
to be detected by the :Tutor command.

It is recommended to use a less formal style when writing tutorials than in
regular documentation (unless the content requires it).

Plugins and modules included with Nvim

Nvim includes various Lua and Vim plugins or modules which may provide commands (such as :TOhtml) or modules that you can optionally require() or :packadd. The Lua ones are not part of the lua-stdlib, that is, they are not available from the global vim module namespace. Some of the plugins are loaded by default while others are not loaded until requested by :packadd.

Standard plugins

standard-plugin-list

Help-link	Loaded	Short description
dir	Yes	Directory listing for :edit
difftool	No	Compares directories (and files) side-by-side
editorconfig	Yes	Detect and interpret editorconfig
ft-shada	Yes	Allows editing binary shada files
man.lua	Yes	View manpages in Nvim
|matchit|	Yes	Extended % matching
matchparen	Yes	Highlight matching pairs
netrw	No	Reading and writing files over a network
zip	Yes	Read-only zip archive browser
package-cfilter	No	Filtering quickfix/location list
package-justify	No	Justify text
package-nohlsearch	No	Automatically run :nohlsearch
package-spellfile	Yes	Install spellfile if missing
package-termdebug	No	Debug inside Nvim with gdb
package-tohtml	No	Convert buffer to html, syntax included
package-undotree	No	Interactive textual undotree
pi_gzip.txt	Yes	Reading and writing compressed files
pi_msgpack.txt	No	msgpack utilities
pi_paren.txt	Yes	Highlight matching parens
pi_spec.txt	Yes	Filetype plugin to work with rpm spec files
pi_swapmouse	No	Swap meaning of left and right mouse buttons
pi_tar.txt	Yes	Tar file explorer
pi_tutor.txt	Yes	Interactive tutorial
old-zip	No	Legacy zip archive explorer

Builtin plugin: dir

dir

Nvim opens a directory listing when you :edit a directory path, handled by the builtin "dir" plugin. The listing is read-only, dir.lua does not provide actions which modify the filesystem.

Each "dir" buffer is initialized as follows:

- Sets 'filetype' to "directory".
- Sets current-directory via :bcd, so gf, :! and friends work as expected.
- Keeps alternate-file, so CTRL-^ returns to the buffer you came from.

g:loaded_nvim_dir_plugin

To disable the built-in directory browser, set this before startup:

```
vim.g.loaded_nvim_dir_plugin = 1
```

GLOBAL MAPPINGS

dir-mappings

- - opens the parent directory of the current file or directory.
- {count}- is like -, but a count of 1 opens the global working directory, and a higher count goes up that many levels.

BUFFER-LOCAL MAPPINGS

dir-buffer-mappings

- <CR> opens the file or directory under the cursor.
- a opens the file or directory under the cursor in a vertical split.

- o opens the file or directory under the cursor in a horizontal split.
- - opens the parent directory.
- R reloads the directory listing.

a and o are available for local directories and keep focus in the listing.
'splitright' and 'splitbelow' control where the new window appears.

These keys map to <Plug>(nvim-dir-open), <Plug>(nvim-dir-vsplit),
<Plug>(nvim-dir-split), <Plug>(nvim-dir-up), and <Plug>(nvim-dir-reload); map those
to use different keys. Default mappings are skipped when the target <Plug>
mapping is already mapped. The default "-", "a", and "o" mappings are also
skipped when their keys are already mapped.

dir-config

Directory buffers follow the global 'hidden' option by default. To delete them
after use:

```
autocmd FileType directory setlocal bufhidden=delete
```

A discarded listing is rebuilt on the next visit, so the cursor starts at the
first entry instead of the one it was left on. "wipe" discards the buffer
itself, leaving no alternate-file; see 'bufhidden'.

Reshaping the listing dir-render

DirReadPost

A User autocommand fired after each listing is rendered, including reloads.
The buffer is writable for the duration, so a handler can sort or filter it
with ordinary commands, and the cursor is placed afterwards.

Handlers may reorder or remove lines, but each remaining line must still be an
entry name: dir-buffer-mappings resolve the line under the cursor against the
buffer name, so rewriting line text makes <CR> open a nonexistent path.

Sort directories last:

```
autocmd User DirReadPost silent keeppatterns sort r /\/$/
```

Hide dot-prefixed entries:

```
autocmd User DirReadPost silent keeppatterns g/^\./d _
```

Sort by modification time, newest first:

```
vim.api.nvim_create_autocmd('User', {
  pattern = 'DirReadPost',
  callback = function(args)
    local dir = vim.api.nvim_buf_get_name(args.buf)
    local names = vim.api.nvim_buf_get_lines(args.buf, 0, -1, true)
    local mtime = {} --- @type table<string, integer>
    for _, name in ipairs(names) do
      local stat = vim.uv.fs_stat(vim.fs.joinpath(dir, name))
      mtime[name] = stat and stat.mtime.sec or 0
    end
    table.sort(names, function(a, b)
      return mtime[a] > mtime[b]
    end)
    vim.api.nvim_buf_set_lines(args.buf, 0, -1, true, names)
  end,
})
```

Decorating the listing dir-decorate

A nvim_set_decoration_provider() sets extmarks on the visible lines of
each redraw, so they survive reordering by a DirReadPost handler.

Classify each entry, and show where a symbolic link points:

```
local ns = vim.api.nvim_create_namespace('my.dir.classify')
local glyph = {
  fifo = '|', socket = '=', char = '%', block = '#',
}
vim.api.nvim_set_decoration_provider(ns, {
  on_win = function(_, _, buf)
    return vim.bo[buf].filetype == 'directory'
  end,
  on_range = function(_, _, buf, row)
    local dir = vim.api.nvim_buf_get_name(buf)
    local name = vim.api.nvim_buf_get_lines(buf, row, row + 1, true)[1]
    local path = vim.fs.joinpath(dir, (name:gsub('/$', '')))
    local stat = vim.uv.fs_lstat(path) or {}
    local exe = stat.type == 'file'
      and bit.band(stat.mode, tonumber('111', 8)) ~= 0
    local char = glyph[stat.type] or (exe and '*')
    if char then
      vim.api.nvim_buf_set_extmark(buf, ns, row, #name, {
        virt_text = { { char, 'Dimmed' } },
        virt_text_pos = 'overlay',
        ephemeral = true,
      })
    end
    if stat.type == 'link' then
      local target = vim.uv.fs_readlink(path) or '?'
      vim.api.nvim_buf_set_extmark(buf, ns, row, 0, {
        virt_text = { { '-> ' .. target, 'Dimmed' } },
        virt_text_pos = 'eol',
        ephemeral = true,
      })
    end
    return row + 1
  end,
})
```

Replacing the directory browser dir-disable

To use another directory browser for the current session, delete the
nvim.dir autocommand group on or after VimEnter and handle FileType "directory".
This clears the built-in directory-opening autocommands.

```
vim.api.nvim_del_augroup_by_name('nvim.dir')
vim.api.nvim_create_autocmd('FileType', {
  pattern = 'directory',
  callback = function(args)
    require('my_browser').open(args.buf, vim.api.nvim_buf_get_name(args.buf))
  end,
})
```

netrw

To enable the legacy "netrw" plugin:

```
:packadd netrw
```

The plugin and its mappings remain loaded (it is a core component used by
other features such as zip). Define replacement keymaps explicitly, for
example:

```
vim.keymap.set('n', '-', function()
  require('my_browser').open_parent()
end)
```

Builtin plugin: difftool difftool

:DiffTool {left} {right} :DiffTool

Compares two directories or files side-by-side.
Supports directory diffing, rename detection, and highlights changes
in quickfix list. Replaces the built-in nvim -d diff mode with this interface.

The plugin is not loaded by default; use :packadd to activate it:

```
:packadd nvim.difftool
```

Example git difftool -d integration using nvim -d replacement:

```
[difftool "nvim_difftool"]
  cmd = nvim -c \"packadd nvim.difftool\" -d \"$LOCAL\" \"$REMOTE\"
[diff]
  tool = nvim_difftool
```

open({left}, {right}, {opt}) difftool.open()

Diff two files or directories

Parameters:

- {left}   (string)
- {right} (string)
- {opt}   (table?)
    - {rename.detect} (boolean, default: false) Whether to
      detect renames
    - {rename.similarity} (number, default: 0.5) Minimum
      similarity for rename detection (0 to 1)
    - {rename.chunk_size} (number, default: 4096) Maximum
      chunk size to read from files for similarity calculation
    - {ignore} (string[], default: {}) List of file patterns
      to ignore (for example: '.git', '*.log')
    - {method} ('auto'|'builtin'|'diffr', default: auto) Diff
      method to use
    - {rename} (table) Controls rename detection

Builtin plugin: editorconfig

editorconfig

EditorConfig is like 'modeline' for an entire (recursive) directory. When a file is opened, after running ftplugins and FileType autocommands, the EditorConfig feature searches all parent directories of that file for .editorconfig files, parses them, and applies their properties. For more information see https://editorconfig.org/.

Example .editorconfig file:

```
root = true

[*]
charset = utf-8
end_of_line = lf
indent_size = 4
indent_style = space
max_line_length = 42
trim_trailing_whitespace = true

[*.{diff,md}]
trim_trailing_whitespace = false
```

g:editorconfig b:editorconfig

EditorConfig is enabled by default. To disable it, add to your config:

```
vim.g.editorconfig = false
```

(Vimscript: let g:editorconfig = v:false). It can also be disabled per-buffer by setting the b:editorconfig buffer-local variable to false.

Nvim stores the applied properties in b:editorconfig if it is not false.

editorconfig-custom-properties

New properties can be added by adding a new entry to the "properties" table. The table key is a property name and the value is a callback function which accepts the number of the buffer to be modified, the value of the property in the .editorconfig file, and (optionally) a table containing all of the other properties and their values (useful for properties which depend on other properties). The value is always a string and must be coerced if necessary. Example:

```
require('editorconfig').properties.foo = function(bufnr, val, opts)
  if opts.charset and opts.charset ~= "utf-8" then
    error("foo can only be set when charset is utf-8", 0)
  end
  vim.b[bufnr].foo = val
end
```

editorconfig-properties

The following properties are supported by default:

charset editorconfig.charset

One of "utf-8", "utf-8-bom", "latin1", "utf-16be", or "utf-16le". Sets the 'fileencoding' and 'bomb' options.

end_of_line editorconfig.end_of_line

One of "lf", "crlf", or "cr". These correspond to setting 'fileformat' to "unix", "dos", or "mac", respectively.

indent_size editorconfig.indent_size

A number indicating the size of a single indent. Alternatively, use the value "tab" to use the value of the tab_width property. Sets the 'shiftwidth' and 'softtabstop' options. If this value is not "tab" and the tab_width property is not set, 'tabstop' is also set to this value.

indent_style editorconfig.indent_style

One of "tab" or "space". Sets the 'expandtab' option.

insert_final_newline editorconfig.insert_final_newline

"true" or "false" to ensure the file always has a trailing newline as its last byte. Sets the 'fixendofline' and 'endofline' options.

max_line_length editorconfig.max_line_length

A number indicating the maximum length of a single line. Sets the 'textwidth' option.

root editorconfig.root

If "true", then stop searching for .editorconfig files in parent directories. This property must be at the top-level of the .editorconfig file (i.e. it must not be within a glob section). It only controls the search and is excluded from property callbacks and b:editorconfig.

spelling_language editorconfig.spelling_language

A code of the format ss or ss-TT, where ss is an ISO 639 language code and TT is an ISO 3166 territory identifier. Sets the 'spelllang' option.

tab_width editorconfig.tab_width

The display size of a single tab character. Sets the 'tabstop' option.

trim_trailing_whitespace editorconfig.trim_trailing_whitespace

When "true", trailing whitespace is automatically removed when the buffer is written.

Builtin plugin: spellfile package-spellfile

Asks the user to download missing spellfiles. The spellfile is written to stdpath('data') .. 'site/spell' or the first writable directory in the 'runtimepath'.

The plugin can be disabled by setting g:loaded_spellfile_plugin = 1.

nvim.spellfile.Config
A table with the following fields:

Fields:

- {confirm} (boolean, default: true) Whether to ask user to confirm download.
- {timeout_ms} (integer, default: 15000) Number of milliseconds after which the vim.net.request() times out.
- {url} (string) The base URL from where the spellfiles are downloaded. Uses g:spellfile_URL if it's set, otherwise https://ftp.nluug.nl/pub/vim/runtime/spell.

config({opts}) spellfile.config()

Configure spellfile download options. Omit {opts} to retrieve the current configuration. Otherwise, update only the supplied fields.

For example:

```
require('nvim.spellfile').config({ url = '...' })
```

Parameters:

- {opts} (Partial<nvim.spellfile.Config>?)

Return:
(nvim.spellfile.Config?) Current config if {opts} is omitted.

get({lang}) spellfile.get()

Download spellfiles for language {lang} if available.

Parameters:

- {lang} (string) Language code.

Return:
(table?) A table with the following fields:

- {dir} (string)
- {encoding} (string)
- {files} (string[])
- {key} (string)
- {lang} (string)

Builtin plugin: tohtml

package-tohtml

:[range]TOhtml {file}

:TOhtml

Converts the buffer shown in the current window to HTML, opens the generated HTML in a new split window, and saves its contents to {file}. If {file} is not given, a temporary file (created by tempname()) is used.

The plugin is not loaded by default; use :packadd to activate it:

```
:packadd nvim.tohtml
```

tohtml({winid}, {opt})

tohtml.tohtml()

Converts the buffer shown in the window {winid} to HTML and returns the output as a list of string.

Parameters:

- {winid} (integer?) Window to convert (defaults to current window)
- {opt} (table?) Optional parameters.
  - {font}? (string[]|string, default: guifont) Fonts to use.
  - {number_lines}? (boolean, default: false) Show line numbers.
  - {range}? (integer[], default: entire buffer) Range of rows to use.
  - {title}? (string|false, default: buffer name) Title tag to set in the generated HTML code.
  - {width}? (integer, default: 'textwidth' if non-zero or window width otherwise) Width used for items which are either right aligned or repeat a character infinitely.

Return:
(string[])

Builtin plugin: undotree

package-undotree

open({opts})

undotree.open()

Open a window that displays a textual representation of the undo-tree, or closes the window if it is already open. Can also be shown with :Undotree.

:Undotree

While in the window, moving the cursor changes the undo.

The plugin is not loaded by default; use :packadd to activate it:

```
:packadd nvim.undotree
```

Parameters:

- {opts} (table?) A table with the following fields:
  - {bufnr} (integer?) Buffer to draw the tree into. If omitted, a new buffer is created.
  - {command} (string?) Vimscript command to create the

window. Default value is "30vnew". Only used when {winid} is nil.

- {title} ((string|fun(bufnr:integer):string?)?) Title of the window. If a function, it accepts the buffer number of the source buffer as its only argument and should return a string.
- {winid} (integer?) Window id to display the tree buffer in. If omitted, a new window is created with {command}.

Return:

(boolean?) Returns true if the window was already open, nil otherwise

Providers

Nvim delegates some features to dynamic "providers". This document describes the providers and how to install them. E319
Use of a feature requiring a missing provider is an error:

```
E319: No "foo" provider found. Run ":checkhealth vim.provider"
```

Run the :checkhealth command, and review the sections below.

Python integration provider-python

Nvim supports Python remote-plugins and the Vim legacy python3 and pythonx interfaces (which are implemented as remote-plugins).

Note: Only the Vim 7.3 legacy interface is supported, not later features such as python-bindeval (Vim 7.4); use the Nvim API instead. Python 2 is not supported.

PYTHON QUICKSTART

To use Python plugins, you need the "pynvim" module. Run :checkhealth to see if you already have it (some package managers install the module with Nvim itself).

For Python 3 plugins:

1. Make sure Python 3.9+ is available in your $PATH.
2. Install either uv (https://docs.astral.sh/uv/) or pipx (https://pipx.pypa.io/stable/).
3. Install the module:

```
pipx install pynvim
# or:
uv tool install --upgrade pynvim
```

The `--upgrade` flag ensures that you get the latest version even if a previous version was already installed.

See also python-virtualenv.

PYTHON PROVIDER CONFIGURATION

g:python3_host_prog

Command to start Python 3 (executable, not directory). Setting this makes startup faster. Useful for working with virtualenvs. Must be set before any check for has("python3").

```
let g:python3_host_prog = '/path/to/python3'
```

g:loaded_python3_provider

To disable Python 3 support:

```
let g:loaded_python3_provider = 0
```

PYTHON VIRTUALENVS

python-virtualenv

Using pynvim 0.6.0+ installed via uv or pipx, Nvim will automatically detect pynvim even if other Python virtual environments are activated (technical note: via the "pynvim-python" global python tool). For older pynvim (or older Neovim), where detection involved finding the first Python interpreter and checking if it could import pynvim, automatic detection would fail when another virtual environment is active. Upgrading to the latest pynvim is the recommended solution to this; but if that's not an option, then you can set the variable g:python3_host_prog in `init.vim` to point to the full path to the Python interpreter where `pynvim` is installed, e.g.:

```
let g:python3_host_prog = '/path/to/pynvim-venv/bin/python'
```

See also: https://github.com/zchee/deoplete-jedi/wiki/Setting-up-Python-for-Neovim

Ruby integration provider-ruby

Nvim supports Ruby remote-plugins and the Vim legacy ruby-vim interface (which is itself implemented as a Nvim remote-plugin).

RUBY QUICKSTART

To use Ruby plugins with Nvim, install the latest "neovim" RubyGem:

```
gem install neovim
```

Run :checkhealth to see if your system is up-to-date.

RUBY PROVIDER CONFIGURATION

g:loaded_ruby_provider

To disable Ruby support:

```
let g:loaded_ruby_provider = 0
```

g:ruby_host_prog

Command to start the Ruby host. By default this is "neovim-ruby-host". With project-local Ruby versions (via tools like RVM or rbenv) setting this can avoid the need to install the "neovim" gem in every project.

To use an absolute path (e.g. to an rbenv installation):

```
let g:ruby_host_prog = '~/.rbenv/versions/2.4.1/bin/neovim-ruby-host'
```

To use the RVM "system" Ruby installation:

```
let g:ruby_host_prog = 'rvm system do neovim-ruby-host'
```

Perl integration

provider-perl

Nvim supports Perl remote-plugins on Unix platforms. Support for polling STDIN on MS-Windows is currently lacking from all known event loop implementations. The Vim legacy perl-vim interface is also supported (which is itself implemented as a Nvim remote-plugin). https://github.com/jacquesg/p5-Neovim-Ext

Note: Only perl versions from 5.22 onward are supported.

PERL QUICKSTART

To use perl remote-plugins with Nvim, install the "Neovim::Ext" cpan package:

```
cpanm -n Neovim::Ext
```

Run :checkhealth to see if your system is up-to-date.

PERL PROVIDER CONFIGURATION

g:loaded_perl_provider

To disable Perl support:

```
:let g:loaded_perl_provider = 0
```

g:perl_host_prog

Command to start the Perl executable. Must be set before any check for has("perl").

```
let g:perl_host_prog = '/path/to/perl'
```

Node.js integration

provider-nodejs

Nvim supports Node.js remote-plugins. https://github.com/neovim/node-client/

NODEJS QUICKSTART

To use javascript remote-plugins with Nvim, install the "neovim" npm package:

```
npm install -g neovim
```

Run :checkhealth to see if your system is up-to-date.

NODEJS PROVIDER CONFIGURATION

g:loaded_node_provider

To disable Node.js support:

```
:let g:loaded_node_provider = 0
```

g:node_host_prog

Command to start the Node.js host. Setting this makes startup faster.

By default, Nvim searches for "neovim-node-host" using "npm root -g", which can be slow. To avoid this, set g:node_host_prog to the host path:

```
let g:node_host_prog = '/usr/local/bin/neovim-node-host'
```

Clipboard integration

provider-clipboard clipboard

Nvim has no direct connection to the system clipboard. Instead it depends on a provider which transparently uses shell commands to communicate with the system clipboard or any other clipboard "backend".

To ALWAYS use the clipboard for ALL operations (instead of interacting with the "+" and/or "*" registers explicitly):

```
set clipboard+=unnamedplus
```

See 'clipboard' for details and options.

clipboard-tool

The presence of a working clipboard tool implicitly enables the "+" and "*" registers. Nvim supports these clipboard tools, in order of priority:

- g:clipboard : User override (if set to a dict or any string "name" below; e.g. `g:clipboard="tmux"` forces tmux clipboard and skips auto-detection).
- "pbcopy" : pbcopy, pbpaste (macOS)
- "wl-copy" : wl-copy, wl-paste (if $WAYLAND_DISPLAY is set)
- "wayclip" : waycopy, waypaste (if $WAYLAND_DISPLAY is set)
- "xsel" : xsel (if $DISPLAY is set)
- "xclip" : xclip (if $DISPLAY is set)
- "lemonade" : lemonade (for SSH) https://github.com/pocke/lemonade
- "doitclient": doitclient (for SSH) https://www.chiark.greenend.org.uk/~sgtatham/doit/
- "win32yank" : win32yank (Windows)
- "putclip" : putclip, getclip (Windows) https://cygwin.com/packages/summary/cygutils.html
- "clip" : clip, powershell (Windows) https://learn.microsoft.com/en-us/windows-server/administration/windows-commands/clip
- "termux" : termux (via termux-clipboard-set, termux-clipboard-get)
- "tmux" : tmux (if $TMUX is set)
- "osc52" : clipboard-osc52 (if supported by your terminal)

g:clipboard

To configure a custom clipboard tool, set `g:clipboard` to a string name (from the above clipboard-tool list), or dict (to explicitly specify the shell commands or lambda functions) before clipboard providers are initialized.

Note: Clipboard providers are initialized by calling `has('clipboard')`, which is best avoided before setting `g:clipboard`. See "G:CLIPBOARD SETTINGS ARE NOT USED" in faq-runtime for workarounds.

If "cache_enabled" is TRUE then when a selection is copied Nvim will cache the selection until the copy command process dies. When pasting, if the copy process has not died the cached selection is applied.

The "copy" function stores a list of lines and the register type. The "paste" function returns the clipboard as a `[lines, regtype]` list, where `lines` is a list of lines and `regtype` is a register type conforming to setreg().

Example: set to "osc52" to force OSC52, skipping auto-detection of terminal support:

```
let g:clipboard = 'osc52'
```

Example: set to "wayclip" to force waycopy/waypaste:

```
let g:clipboard = 'wayclip'
```

Example: set to a dict which integrates the tmux clipboard:

```
let g:clipboard = {
  \   'name': 'myClipboard',
  \   'copy': {
  \      '+': ['tmux', 'load-buffer', '-'],
  \      '*': ['tmux', 'load-buffer', '-'],
  \    },
  \   'paste': {
  \      '+': ['tmux', 'save-buffer', '-'],
  \      '*': ['tmux', 'save-buffer', '-'],
  \   },
  \   'cache_enabled': 1,
  \ }
```

Example: set to a dict which uses g:foo as a fake clipboard:

```
let g:clipboard = {
  \   'name': 'myClipboard',
  \   'copy': {
  \      '+': {lines, regtype -> extend(g:, {'foo': [lines, regtype]}) },
  \      '*': {lines, regtype -> extend(g:, {'foo': [lines, regtype]}) },
  \    },
  \   'paste': {
  \      '+': {-> get(g:, 'foo', [])},
  \      '*': {-> get(g:, 'foo', [])},
  \   },
  \ }
```

clipboard-wsl

For Windows WSL, try this g:clipboard definition:

```
let g:clipboard = {
  \   'name': 'WslClipboard',
  \   'copy': {
  \      '+': 'clip.exe',
  \      '*': 'clip.exe',
  \    },
  \   'paste': {
  \      '+': 'powershell.exe -NoLogo -NoProfile -c [Console]::Out.Write($(Get-Clipboard -Raw).tostring().replace("`r", ""))',
  \      '*': 'powershell.exe -NoLogo -NoProfile -c [Console]::Out.Write($(Get-Clipboard -Raw).tostring().replace("`r", ""))',
  \   },
  \   'cache_enabled': 0,
  \ }
```

clipboard-osc52

Nvim bundles a clipboard provider that allows copying to the system clipboard using OSC 52, an "Operating System Command" control-sequence that causes the terminal emulator to write to or read from the system clipboard.

When Nvim is running in the TUI, it automatically detects host terminal support for OSC 52. If successful, then Nvim will use OSC 52 for copying and pasting if no other clipboard-tool is found and when 'clipboard' is unset. **NOTE:** Using a terminal multiplexer (e.g. tmux) may inhibit automatic OSC 52 support detection.

g:termfeatures

To disable the automatic detection, set the "osc52" key of g:termfeatures to false early in your config. Example:

```
local termfeatures = vim.g.termfeatures or {}
termfeatures.osc52 = false
vim.g.termfeatures = termfeatures
```

To force Nvim to use the OSC 52 provider you can set g:clipboard:

```
vim.g.clipboard = 'osc52'
```

Which is equivalent to:

```
vim.g.clipboard = {
  name = 'OSC 52',
  copy = {
    ['+'] = require('vim.ui.clipboard.osc52').copy('+'),
    ['*'] = require('vim.ui.clipboard.osc52').copy('*'),
  },
  paste = {
    ['+'] = require('vim.ui.clipboard.osc52').paste('+'),
    ['*'] = require('vim.ui.clipboard.osc52').paste('*'),
  },
}
```

Note: not all terminal emulators support reading from the system clipboard (and even for those that do, users should be aware of the security implications), so using OSC 52 for pasting may not be possible (and not necessary, because you can paste instead using your system paste function). Users may need to configure their terminal emulator to allow reading from the clipboard.

Paste

provider-paste **paste**

"Paste" is a separate concept from clipboard: paste means "dump a bunch of text to the editor", whereas clipboard provides features like quote+ to get and set the OS clipboard directly. For example, middle-click or CTRL-SHIFT-v (macOS: CMD-v) in your terminal is "paste", not "clipboard": the terminal application (Nvim) just gets a stream of text, it does not interact with the clipboard directly.

bracketed-paste-mode

Pasting in the TUI depends on the "bracketed paste" terminal capability, which allows terminal applications to distinguish between user input and pasted text. https://cirw.in/blog/bracketed-paste This works automatically if your terminal supports it.

ui-paste

GUIs can paste by calling nvim_paste().

PASTE BEHAVIOR

Paste inserts text after the cursor. Lines break at <NL>, <CR>, and <CR><NL>. When pasting a huge amount of text, screen-updates are throttled and the message area shows a "..." pulse.

In cmdline-mode only the first line is pasted, to avoid accidentally executing many commands. Use the cmdline-window if you really want to paste multiple lines to the cmdline.

You can implement a custom paste handler by redefining vim.paste(). Example:

```
vim.paste = (function(lines, phase)
  vim.api.nvim_put(lines, 'c', true, true)
end)
```

X11 selection mechanism

clipboard-x11 **x11-selection**

X11 clipboard providers store text in "selections". Selections are owned by an application, so when the application gets closed, the selection text is lost. The contents of selections are held by the originating application (e.g., upon a copy), and only passed to another application when that other application requests them (e.g., upon a paste).

primary-selection quotestar quoteplus quote+

There are three documented X11 selections: PRIMARY, SECONDARY, and CLIPBOARD. CLIPBOARD is typically used in X11 applications for copy/paste operations (CTRL-c/CTRL-v), while PRIMARY is used for the last selected text, which is generally inserted with the middle mouse button.

Nvim's X11 clipboard providers only use the PRIMARY and CLIPBOARD selections, for the "*" and "+" registers, respectively.

This subject is introduced in section 30.1 of the user manual.

1. Using QuickFix commands

Quickfix E42

Vim has a special mode to speedup the edit-compile-edit cycle. This is inspired by the quickfix option of the Manx's Aztec C compiler on the Amiga. The idea is to save the error messages from the compiler in a file and use Vim to jump to the errors one by one. You can examine each problem and fix it, without having to remember all the error messages.

In Vim the quickfix commands are used more generally to find a list of positions in files. For example, :vimgrep finds pattern matches. You can use the positions in a script with the getqflist() function. Thus you can do a lot more than the edit/compile/fix cycle!

If you have the error messages in a file you can start Vim with:

```
vim -q filename
```

From inside Vim an easy way to run a command and handle the output is with the :make command (see below).

The 'errorformat' option should be set to match the error messages from your compiler (see errorformat below). Vim uses it to extract information such as the file name, line number and message from each line of compiler output. Lines that do not match are kept as invalid entries and are skipped by commands such as :cnext. Use :clist! to display them as well.

quickfix-stack quickfix-ID

Each quickfix list has a unique identifier called the quickfix ID and this number will not change within a Vim session. The getqflist() function can be used to get the identifier assigned to a list. There is also a quickfix list number, which is its position in the quickfix stack. This number may change when lists are added or removed, or when more than 'chistory' lists are kept. Use the ID when a script needs to refer to the same list reliably; use the list number when referring to its current position in the stack.

location-list E776

A location list is a quickfix list tied to one window. Each window can have a separate location list, and commands such as :lvimgrep, :lgrep, :lhelpgrep and :lmake use it instead of the global quickfix list. The corresponding commands without the "l" prefix use the quickfix list.

location-list-file-window

The location list is independent of the quickfix list. A location list can be associated with only one window.

When a window with a location list is split, the new window gets a copy of the location list. When there are no longer any references to a location list, the location list is destroyed.

quickfix-changedtick

Every quickfix and location list has a read-only changedtick variable that tracks the total number of changes made to the list. Every time the quickfix list is modified, this count is incremented. This can be used to perform an action only when the list has changed. The getqflist() and getloclist() functions can be used to query the current value of changedtick. You cannot change the changedtick variable.

The following quickfix commands can be used. The location list commands are similar to the quickfix commands, replacing the 'c' prefix in the quickfix command with 'l'.

E924

If the current window was closed by an autocommand while processing a location list command, it will be aborted.

E925 E926

If the current quickfix or location list was changed by an autocommand while processing a quickfix or location list command, it will be aborted.

:cc

:cc[!] [nr] Display error [nr]. If [nr] is omitted, the same
:[nr]cc[!] error is displayed again. Without [!] this doesn't work when jumping to another buffer, the current buffer has been changed, there is the only window for the buffer and both 'hidden' and 'autowrite' are off. When jumping to another buffer with [!] any changes to the current buffer are lost, unless 'hidden' is set or there is another window for this buffer. The 'switchbuf' settings are respected when jumping to a buffer. When used in the quickfix window the line number can be used, including "." for the current line and "$" for the last line.

:ll

:ll[!] [nr] Same as ":cc", except the location list for the
:[nr]ll[!] current window is used instead of the quickfix list.

:cn :cne :cnext E553
:[count]cn[ext][!] Display the [count] next error in the list that includes a file name. Entries without a file name are skipped, since Vim cannot use them to jump to a file. If there are no file names at all, go to the [count] next error. See :cc for [!] and 'switchbuf'.

]q

]q Mapped to :cnext. default-mappings

:[count]cN[ext][!] :cp :cprevious :cprev :cN :cNext
:[count]cp[revious][!] Display the [count] previous error in the list that includes a file name. Entries without a file name are skipped, since Vim cannot use them to jump to a file. If there are no file names at all, go to the [count] previous error. See :cc for [!] and 'switchbuf'.

[q

[q Mapped to :cprevious. default-mappings

:lne :lnext
:[count]lne[xt][!] Same as ":cnext", except the location list for the current window is used instead of the quickfix list.

]l

]l Mapped to :lnext. default-mappings

:[count]lN[ext][!] :lp :lprevious :lprev :lN :lNext
:[count]lp[revious][!] Same as ":cNext" and ":cprevious", except the location list for the current window is used instead of the quickfix list.

[l

[l Mapped to :lprevious. default-mappings

:cabo :cabove
:[count]cabo[ve] Go to the [count] error above the current line in the current buffer. If [count] is omitted, then 1 is used. If there are no errors, then an error message is displayed. Assumes that the entries in a quickfix list are sorted by their buffer number and line number. If there are multiple errors on the same line, then only the first entry is used. If [count] exceeds the number of entries above the current line, then the first error in the file is selected.

:lab :labove
:[count]lab[ove] Same as ":cabove", except the location list for the current window is used instead of the quickfix list.

:cbel :cbelow
:[count]cbel[ow] Go to the [count] error below the current line in the current buffer. If [count] is omitted, then 1 is used. If there are no errors, then an error message is displayed. Assumes that the entries in a quickfix list are sorted by their buffer number and line number. If there are multiple errors on the same line, then only the first entry is used. If [count] exceeds the number of entries below the current line, then the last error in the file is selected.

:lbel :lbelow
:[count]lbel[ow] Same as ":cbelow", except the location list for the current window is used instead of the quickfix list.

:cbe :cbefore
:[count]cbe[fore] Go to the [count] error before the current cursor position in the current buffer. If [count] is omitted, then 1 is used. If there are no errors, then an error message is displayed. Assumes that the entries in a quickfix list are sorted by their buffer, line and column numbers. If [count] exceeds the number of entries before the current position, then the first error in the file is selected.

:lbe :lbefore
:[count]lbe[fore] Same as ":cbefore", except the location list for the current window is used instead of the quickfix list.

:caf :cafter
:[count]caf[ter] Go to the [count] error after the current cursor position in the current buffer. If [count] is omitted, then 1 is used. If there are no errors, then an error message is displayed. Assumes that the entries in a quickfix list are sorted by their buffer, line and column numbers. If [count] exceeds the number of entries after the current position, then the last error in the file is selected.

:laf :lafter
:[count]laf[ter] Same as ":cafter", except the location list for the current window is used instead of the quickfix list.

:cnf :cnfile
:[count]cnf[ile][!] Display the first error in the [count] next file in

the list that includes a file name. If there are no file names at all or if there is no next file, go to the [count] next error. See :cc for [!] and 'switchbuf'.

]_CTRL-Q

]_CTRL-Q Mapped to :cnfile. default-mappings

:lnf :lnfile

:[count]lnf[ile][!] Same as ":cnfile", except the location list for the current window is used instead of the quickfix list.

]_CTRL-L

]_CTRL-L Mapped to :lnfile. default-mappings

:cpf :cpfile :cNf :cNfile

:[count]cNf[ile][!]
:[count]cpf[ile][!] Display the last error in the [count] previous file in the list that includes a file name. If there are no file names at all or if there is no next file, go to the [count] previous error. See :cc for [!] and 'switchbuf'.

[_CTRL-Q

[_CTRL-Q Mapped to :cpfile. default-mappings

:lpf :lpfile :lNf :lNfile

:[count]lNf[ile][!]
:[count]lpf[ile][!] Same as ":cNfile" and ":cpfile", except the location list for the current window is used instead of the quickfix list.

[_CTRL-L

[_CTRL-L Mapped to :lpfile. default-mappings

:crewind :cr

:cr[ewind][!] [nr] Display error [nr]. If [nr] is omitted, the FIRST error is displayed. See :cc.

[Q

[Q Mapped to :crewind. default-mappings

:lrewind :lr

:lr[ewind][!] [nr] Same as ":crewind", except the location list for the current window is used instead of the quickfix list.

[L

[L Mapped to :lrewind. default-mappings

:cfirst :cfir

:cfir[st][!] [nr] Same as ":crewind".

:lfirst :lfir

:lfir[st][!] [nr] Same as ":lrewind".

:clast :cla

:cla[st][!] [nr] Display error [nr]. If [nr] is omitted, the LAST error is displayed. See :cc.

]Q

]Q Mapped to :clast.

:llast :lla

:lla[st][!] [nr] Same as ":clast", except the location list for the current window is used instead of the quickfix list.

]L

]L Mapped to :llast.

:cq :cquit

:cq[uit][!]
:{N}cq[uit][!]
:cq[uit][!] {N} Quit Vim with error code {N}. {N} defaults to one. Useful when Vim is called from another program: e.g., a compiler will not compile the same file again, git commit will abort the committing process, fc (built-in for shells like bash and zsh) will not execute the command, etc.
{N} can also be zero, in which case Vim exits normally.
WARNING: This abandons changes in all files, like :qall!.
The [!] does not change this. Vim returns a non-zero exit code, unless {N} is zero.

:cf :cfi :cfile

:cf[ile][!] [errorfile] Read the error file and jump to the first error. This is done automatically when Vim is started with the -q option. You can use this command when you keep Vim running while compiling. If you give the name of the errorfile, the 'errorfile' option will be set to [errorfile]. See :cc for [!].
If the encoding of the error file differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:lf :lfi :lfile
:lf[ile][!] [errorfile] Same as ":cfile", except the location list for the
current window is used instead of the quickfix list.
You can not use the -q command-line option to set
the location list.

:cg[etfile] [errorfile] :cg :cgetfile
Read the error file. Just like ":cfile" but don't
jump to the first error.
If the encoding of the error file differs from the
'encoding' option, you can use the 'makeencoding'
option to specify the encoding.

:lg[etfile] [errorfile] :lg :lge :lgetfile
Same as ":cgetfile", except the location list for the
current window is used instead of the quickfix list.

:caddf :caddfile
:caddf[ile] [errorfile] Read the error file and add the errors from the
errorfile to the current quickfix list. If a quickfix
list is not present, then a new list is created.
If the encoding of the error file differs from the
'encoding' option, you can use the 'makeencoding'
option to specify the encoding.

:laddf :laddfile
:laddf[ile] [errorfile] Same as ":caddfile", except the location list for the
current window is used instead of the quickfix list.

The following commands read error messages from a buffer:
:cbuffer creates a list and jumps to its first error, :cgetbuffer creates
a list without jumping, and :caddbuffer adds entries to the current list
without changing the cursor position. The corresponding commands with an "l"
prefix use the location list.

:cb :cbuffer E681
:[range]cb[uffer][!] [bufnr]
Read the error list from the current buffer.
When [bufnr] is given it must be the number of a
loaded buffer. That buffer will then be used instead
of the current buffer.
A range can be specified for the lines to be used, for
example :10,20cbuffer. Otherwise all lines in the
buffer are used.
See :cc for [!].

:lb :lbuffer
:[range]lb[uffer][!] [bufnr]
Same as ":cbuffer", except the location list for the
current window is used instead of the quickfix list.

:cgetb :cgetbuffer
:[range]cgetb[uffer] [bufnr]
Read the error list from the current buffer. Just
like ":cbuffer" but don't jump to the first error.

:lgetb :lgetbuffer
:[range]lgetb[uffer] [bufnr]
Same as ":cgetbuffer", except the location list for
the current window is used instead of the quickfix
list.

:cad :cadd :caddbuffer
:[range]cad[dbuffer] [bufnr]
Read the error list from the current buffer and add
the errors to the current quickfix list. If a
quickfix list is not present, then a new list is
created. Otherwise, same as ":cbuffer".

:laddb :laddbuffer
:[range]laddb[uffer] [bufnr]
Same as ":caddbuffer", except the location list for
the current window is used instead of the quickfix
list.

The following commands create or update a quickfix list from an expression:
:cexpr creates a list and jumps to its first error, :cgetexpr creates a
list without jumping, and :caddexpr adds entries to the current list without
changing the cursor position. The corresponding commands with an "l" prefix
use the location list.

:cex :cexpr E777
:cex[pr][!] {expr} Create a quickfix list using the result of {expr} and
jump to the first error.
If {expr} is a String, then each newline terminated
line in the String is processed using the global value
of 'errorformat' and the result is added to the
quickfix list.
If {expr} is a List, then each String item in the list
is processed and added to the quickfix list. Non
String items in the List are ignored.
See :cc for [!].
Examples:

```
:cexpr system('grep -n xyz *')
:cexpr getline(1, '$')
```

:lex :lexpr
:lex[pr][!] {expr} Same as :cexpr, except the location list for the current window is used instead of the quickfix list.

:cgete :cgetexpr
:cgete[xpr] {expr} Create a quickfix list using the result of {expr}. Just like :cexpr, but don't jump to the first error.

:lgete :lgetexpr
:lgete[xpr] {expr} Same as :cgetexpr, except the location list for the current window is used instead of the quickfix list.

:cadde :caddexpr
:cadde[xpr] {expr} Evaluate {expr} and add the resulting lines to the current quickfix list. If a quickfix list is not present, then a new list is created. The current cursor position will not be changed. See :cexpr for more information.
Example:

```
:g/mypattern/caddexpr expand("%") .. ":" .. line(".") ..  ":" .. getline(".")
```

:lad :ladd :laddexpr
:lad[dexpr] {expr} Same as ":caddexpr", except the location list for the current window is used instead of the quickfix list.

:cl :clist
:cl[ist] [from] [, [to]]
List all errors that are valid quickfix-valid. If numbers [from] and/or [to] are given, the respective range of errors is listed. A negative number counts from the last error backwards, -1 being the last error.
The :filter command can be used to display only the quickfix entries matching a supplied pattern. The pattern is matched against the filename, module name, pattern and text of the entry.
For example, :filter /\.c:/clist lists only entries whose displayed text contains .c:. See :filter.

:cl[ist] +{count} List the current and next {count} valid errors. This is similar to ":clist from from+count", where "from" is the current error position.

:cl[ist]! [from] [, [to]]
List all errors.

:cl[ist]! +{count} List the current and next {count} error lines. This is useful to see unrecognized lines after the current one. For example, if ":clist" shows:

8384 testje.java:252: error: cannot find symbol
Then using ":cl! +3" shows the reason:

8384 testje.java:252: error: cannot find symbol
8385: ZexitCode = Fmainx();
8386: ^
8387: symbol: method Fmainx()

:lli[st] [from] [, [to]] :lli :llist
Same as ":clist", except the location list for the current window is used instead of the quickfix list.

:lli[st]! [from] [, [to]]
List all the entries in the location list for the current window.

If you insert or delete lines, mostly the correct error location is still found because hidden marks are used. Sometimes, when the mark has been deleted for some reason, the message "line changed" is shown to warn you that the error location may not be correct. If you quit Vim and start again the marks are lost and the error locations may not be correct anymore.

Two autocommands are available for running commands before and after a quickfix command (':make', ':grep' and so on) is executed. See QuickFixCmdPre and QuickFixCmdPost for details.

QuickFixCmdPost-example

When 'encoding' differs from the locale, the error messages may have a different encoding from what Vim is using. To convert the messages you can use this code:

```
function QfMakeConv()
   let qflist = getqflist()
   for i in qflist
      let i.text = iconv(i.text, "cp936", "utf-8")
   endfor
   call setqflist(qflist)
endfunction

au QuickFixCmdPost make call QfMakeConv()
```

Another option is using 'makeencoding'.

quickfix-title

Every quickfix and location list has a title. By default the title is set to

the command that created the list. The getqflist() and getloclist() functions can be used to get the title of a quickfix and a location list respectively. The setqflist() and setloclist() functions can be used to modify the title of a quickfix and location list respectively. Examples:

```
call setqflist([], 'a', {'title' : 'Cmd output'})
echo getqflist({'title' : 1})
call setloclist(3, [], 'a', {'title' : 'Cmd output'})
echo getloclist(3, {'title' : 1})
```

quickfix-index

When you jump to a quickfix/location list entry using any of the quickfix commands (e.g. :cc, :cnext, :cprev, etc.), that entry becomes the currently selected entry. The index of the currently selected entry in a quickfix/location list can be obtained using the getqflist()/getloclist() functions. Examples:

```
echo getqflist({'idx' : 0}).idx
echo getqflist({'id' : qfid, 'idx' : 0}).idx
echo getloclist(2, {'idx' : 0}).idx
```

For a new quickfix list, the first entry is selected and the index is 1. Any entry in any quickfix/location list can be set as the currently selected entry using the setqflist() function. Examples:

```
call setqflist([], 'a', {'idx' : 12})
call setqflist([], 'a', {'id' : qfid, 'idx' : 7})
call setloclist(1, [], 'a', {'idx' : 7})
```

quickfix-size

You can get the number of entries (size) in a quickfix and a location list using the getqflist() and getloclist() functions respectively. Examples:

```
echo getqflist({'size' : 1})
echo getloclist(5, {'size' : 1})
```

quickfix-context

Any Vim type can be associated as a context with a quickfix or location list. The setqflist() and the setloclist() functions can be used to associate a context with a quickfix and a location list respectively. The getqflist() and the getloclist() functions can be used to retrieve the context of a quickfix and a location list respectively. This is useful for a Vim plugin dealing with multiple quickfix/location lists.
Examples:

```
let somectx = {'name' : 'Vim', 'type' : 'Editor'}
call setqflist([], 'a', {'context' : somectx})
echo getqflist({'context' : 1})

let newctx = ['red', 'green', 'blue']
call setloclist(2, [], 'a', {'id' : qfid, 'context' : newctx})
echo getloclist(2, {'id' : qfid, 'context' : 1})
```

quickfix-parse

You can parse a list of lines using 'errorformat' without creating or modifying a quickfix list using the getqflist() function. Examples:

```
echo getqflist({'lines' : ["F1:10:Line10", "F2:20:Line20"]})
echo getqflist({'lines' : systemlist('grep -Hn quickfix *')})
```

This returns a dictionary where the "items" key contains the list of quickfix entries parsed from lines. The following shows how to use a custom 'errorformat' to parse the lines without modifying the 'errorformat' option:

```
echo getqflist({'efm' : '%f#%l#%m', 'lines' : ['F1#10#Line']})
```

To execute a command for entries or files in a list, use:

	Quickfix list	Location list
Each entry	:cdo	:ldo
Each file	:cfdo	:lfdo

Use :cdo when a command should run for every valid entry, for example :cdo s/old/new/g to change each matching line. Use :cfdo when it should run once for each file, for example :cfdo update to write each affected file once. Add the "l" prefix to use the location list instead.

The commands below describe these differences in more detail.

EXECUTE A COMMAND IN ALL THE BUFFERS IN QUICKFIX OR LOCATION LIST:

:cdo

:cdo[!] {cmd} Execute {cmd} in each valid entry in the quickfix list. It works like doing this:

```
:cfirst
:{cmd}
:cnext
:{cmd}
etc.
```

When the current file can't be abandoned and the [!]
is not present, the command fails.
When going to the next entry fails execution stops.
The last buffer (or where an error occurred) becomes
the current buffer.
{cmd} can contain '|' to concatenate several commands.

Only valid entries in the quickfix list are used.
A range can be used to select entries, e.g.:

```
:10,$cdo cmd
```

To skip entries 1 to 9.

Note: While this command is executing, the Syntax
autocommand event is disabled by adding it to
'eventignore'. This considerably speeds up editing
each buffer.
Also see :bufdo, :tabdo, :argdo, :windo,
:ldo, :cfdo and :lfdo.

:cfd :cfdo

:cfd[o][!] {cmd} Execute {cmd} in each file in the quickfix list.
It works like doing this:

```
:cfirst
:{cmd}
:cnfile
:{cmd}
etc.
```

Otherwise it works the same as :cdo.

:ld :ldo

:ld[o][!] {cmd} Execute {cmd} in each valid entry in the location list
for the current window.
It works like doing this:

```
:lfirst
:{cmd}
:lnext
:{cmd}
etc.
```

Only valid entries in the location list are used.
Otherwise it works the same as :cdo.

:lfd :lfdo

:lfd[o][!] {cmd} Execute {cmd} in each file in the location list for
the current window.
It works like doing this:

```
:lfirst
:{cmd}
:lnfile
:{cmd}
etc.
```

Otherwise it works the same as :ldo.

FILTERING A QUICKFIX OR LOCATION LIST:
cfilter-plugin :Cfilter :Lfilter package-cfilter
If you have too many entries in a quickfix list, you can use the cfilter
plugin to reduce the number of entries. Load the plugin with:

```
packadd cfilter
```

Then you can use the following commands to filter a quickfix/location list:

```
:Cfilter[!] /{pat}/
:Lfilter[!] /{pat}/
```

The :Cfilter command creates a new quickfix list from the entries matching
{pat} in the current quickfix list. {pat} is a Vim regular-expression
pattern. Both the file name and the text of the entries are matched against
{pat}. If the optional ! is supplied, then the entries not matching {pat} are
used. The pattern can be optionally enclosed using one of the following
characters: ', ", /. If the pattern is empty, then the last used search
pattern is used.

The :Lfilter command does the same as :Cfilter but operates on the current
location list.

The current quickfix/location list is not modified by these commands, so you
can go back to the unfiltered list using the :colder/|:lolder| command.

2. The error window

quickfix-window

:cope :copen w:quickfix_title

:cope[n] [height] Open a window to show the current list of errors.

When [height] is given, the window becomes that high (if there is room). When [height] is omitted the window is made ten lines high.

If there already is a quickfix window, it will be made the current window. It is not possible to open a second quickfix window. If [height] is given the existing window will be resized to it.

quickfix-buffer

The window will contain a special buffer, with 'buftype' equal to "quickfix". Don't change this! The window will have the w:quickfix_title variable set which will indicate the command that produced the quickfix list. This can be used to compose a custom status line if the value of 'statusline' is adjusted properly. Whenever this buffer is modified by a quickfix command or function, the b:changedtick variable is incremented. You can get the number of this buffer using the getqflist() and getloclist() functions by passing the "qfbufnr" item. For a location list, this buffer is wiped out when the location list is removed.

:lop :lopen

:lop[en] [height] Open a window to show the location list for the current window. Works only when the location list for the current window is present. You can have more than one location window opened at a time. Otherwise, it acts the same as ":copen".

:ccl :cclose

:ccl[ose] Close the quickfix window.

:lcl :lclose

:lcl[ose] Close the window showing the location list for the current window.

:cw :cwindow

:cw[indow] [height] Open the quickfix window when there are recognized errors. If the window is already open and there are no recognized errors, close the window.

When opening the window and [height] is given, the window becomes that high (if there is room). When [height] is omitted the window is made ten lines high.

:lw :lwindow

:lw[indow] [height] Same as ":cwindow", except use the window showing the location list for the current window.

:cbo :cbottom

:cbo[ttom] Put the cursor in the last line of the quickfix window and scroll to make it visible. This is useful for when errors are added by an asynchronous callback. Only call it once in a while if there are many updates to avoid a lot of redrawing.

:lbo :lbottom

:lbo[ttom] Same as ":cbottom", except use the window showing the location list for the current window.

Normally the quickfix window is at the bottom of the screen.
You can move the window around with window-moving commands.
For example, to move it to the top: CTRL-W K
The 'winfixheight' option will be set, which means that the window will mostly keep its height, ignoring 'winheight' and 'equalalways'. You can change the height manually (e.g., by dragging the status line above it with the mouse).

In the quickfix window, each line is one error. The line number is equal to the error number. The current entry is highlighted with the QuickFixLine highlighting. You can change it to your liking, e.g.:

```
:hi QuickFixLine ctermbg=Yellow guibg=Yellow
```

You can use ":.cc" to jump to the error under the cursor.
Hitting the <Enter> key or double-clicking the mouse on a line has the same effect. The file containing the error is opened in the window above the quickfix window. If there already is a window for that file, it is used instead. If the buffer in the used window has changed, and the error is in another file, jumping to the error will fail. You will first have to make sure the window contains a buffer which can be abandoned.

When you select a file from the quickfix window, Vim first reuses a window that already displays the file. Otherwise it uses a suitable window in the current tab page, or opens a new one. The detailed selection rules are:

1. If a window displaying the selected file is present in the current tabpage

(starting with the window before the quickfix window), then that window is used.
2. If the above step fails and if 'switchbuf' contains "usetab" and a window displaying the selected file is present in any one of the tabpages (starting with the first tabpage) then that window is used.
3. If the above step fails then a window in the current tabpage displaying a buffer with 'buftype' not set (starting with the window before the quickfix window) is used.
4. If the above step fails and if 'switchbuf' contains "uselast", then the previously accessed window is used.
5. If the above step fails then the window before the quickfix window is used. If there is no previous window, then the window after the quickfix window is used.
6. If the above step fails, then a new horizontally split window above the quickfix window is used.

quickfix-winfixbuf

When 'winfixbuf' is set for the window that would be used to display the error, jumping to an error in another buffer is not possible in that window. For a quickfix list Vim then looks for another suitable window, using the previously accessed window if it does not have 'winfixbuf' set, and otherwise splits a new window. For a location list this fails with E1513, because a location list is tied to its window and cannot move to or split off another one. Using [!] skips these checks.

CTRL-W <Enter> CTRL-W <CR>

You can use CTRL-W <Enter> to open a new window and jump to the error there.

When the quickfix window has been filled, two autocommand events are triggered. First the 'filetype' option is set to "qf", which triggers the FileType event (also see qf.vim). Then the BufReadPost event is triggered, using "quickfix" for the buffer name. This can be used to perform some action on the listed errors. Example:

```
au BufReadPost quickfix  setlocal modifiable
        \ | silent exe 'g/^/s//\=line(".") .. " "/'
        \ | setlocal nomodifiable
```

This prepends the line number to each line. Note the use of "\=" in the substitute string of the ":s" command, which is used to evaluate an expression.
The BufWinEnter event is also triggered, again using "quickfix" for the buffer name.

Note: When adding to an existing quickfix list the autocommand are not triggered.

Note: Making changes in the quickfix window has no effect on the list of errors. 'modifiable' is off to avoid making changes. If you delete or insert lines anyway, the relation between the text and the error number is messed up. If you really want to do this, you could write the contents of the quickfix window to a file and use ":cfile" to have it parsed and used as the new error list.

location-list-window

The location list window displays the entries in a location list. When you open a location list window, it is created below the current window and displays the location list for the current window. The location list window is similar to the quickfix window, except that you can have more than one location list window open at a time. When you use a location list command in this window, the displayed location list is used.

When you select a file from the location list window, Vim first uses the window associated with that location list, when possible. Otherwise it reuses a suitable window or opens a new one. The detailed selection rules are:

1. If a non-quickfix window associated with the location list is present in the current tabpage, then that window is used.
2. If the above step fails and if the file is already opened in another window in the current tabpage, then that window is used.
3. If the above step fails and 'switchbuf' contains "usetab" and if the file is opened in a window in any one of the tabpages, then that window is used.
4. If the above step fails then a window in the current tabpage showing a

buffer with 'buftype' not set is used.
5. If the above step fails, then the file is edited in a new window.

In all of the above cases, if the location list for the selected window is not yet set, then it is set to the location list displayed in the location list window.

quickfix-window-ID

You can use the getqflist() and getloclist() functions to obtain the window ID of the quickfix window and location list window respectively (if present). Examples:

```
echo getqflist({'winid' : 1}).winid
echo getloclist(2, {'winid' : 1}).winid
```

getqflist-examples

The getqflist() and getloclist() functions can be used to get the various attributes of a quickfix and location list respectively. Some examples for using these functions are below:

```
" get the title of the current quickfix list
:echo getqflist({'title' : 0}).title

" get the identifier of the current quickfix list
:let qfid = getqflist({'id' : 0}).id

" get the identifier of the fourth quickfix list in the stack
:let qfid = getqflist({'nr' : 4, 'id' : 0}).id

" check whether a quickfix list with a specific identifier exists
:if getqflist({'id' : qfid}).id == qfid

" get the index of the current quickfix list in the stack
:let qfnum = getqflist({'nr' : 0}).nr

" get the items of a quickfix list specified by an identifier
:echo getqflist({'id' : qfid, 'items' : 0}).items

" get the number of entries in a quickfix list specified by an id
:echo getqflist({'id' : qfid, 'size' : 0}).size

" get the context of the third quickfix list in the stack
:echo getqflist({'nr' : 3, 'context' : 0}).context

" get the number of quickfix lists in the stack
:echo getqflist({'nr' : '$'}).nr

" get the number of times the current quickfix list is changed
:echo getqflist({'changedtick' : 0}).changedtick

" get the current entry in a quickfix list specified by an identifier
:echo getqflist({'id' : qfid, 'idx' : 0}).idx

" get all the quickfix list attributes using an identifier
:echo getqflist({'id' : qfid, 'all' : 0})

" parse text from a List of lines and return a quickfix list
:let myList = ["a.java:10:L10", "b.java:20:L20"]
:echo getqflist({'lines' : myList}).items

" parse text using a custom 'efm' and return a quickfix list
:echo getqflist({'lines' : ['a.c#10#Line 10'], 'efm':'%f#%l#%m'}).items

" get the quickfix list window id
:echo getqflist({'winid' : 0}).winid

" get the quickfix list window buffer number
:echo getqflist({'qfbufnr' : 0}).qfbufnr

" get the context of the current location list
:echo getloclist(0, {'context' : 0}).context

" get the location list window id of the third window
:echo getloclist(3, {'winid' : 0}).winid

" get the location list window buffer number of the third window
:echo getloclist(3, {'qfbufnr' : 0}).qfbufnr

" get the file window id of a location list window (winnr: 4)
:echo getloclist(4, {'filewinid' : 0}).filewinid
```

setqflist-examples

The setqflist() and setloclist() functions can be used to set the various attributes of a quickfix and location list respectively. Some examples for using these functions are below:

```
" create an empty quickfix list with a title and a context
:let t = 'Search results'
:let c = {'cmd' : 'grep'}
:call setqflist([], ' ', {'title' : t, 'context' : c})

" set the title of the current quickfix list
:call setqflist([], 'a', {'title' : 'Mytitle'})

" change the current entry in the list specified by an identifier
:call setqflist([], 'a', {'id' : qfid, 'idx' : 10})

" set the context of a quickfix list specified by an identifier
:call setqflist([], 'a', {'id' : qfid, 'context' : {'val' : 100}})

" create a new quickfix list from a command output
:call setqflist([], ' ', {'lines' : systemlist('grep -Hn main *.c')})

" parse text using a custom efm and add to a particular quickfix list
:call setqflist([], 'a', {'id' : qfid,
            \ 'lines' : ["a.c#10#L10", "b.c#20#L20"], 'efm':'%f#%l#%m'})

" add items to the quickfix list specified by an identifier
:let newItems = [{'filename' : 'a.txt', 'lnum' : 10, 'text' : "Apple"},
                \ {'filename' : 'b.txt', 'lnum' : 20, 'text' : "Orange"}]
:call setqflist([], 'a', {'id' : qfid, 'items' : newItems})

" empty a quickfix list specified by an identifier
:call setqflist([], 'r', {'id' : qfid, 'items' : []})

" free all the quickfix lists in the stack
:call setqflist([], 'f')

" set the title of the fourth quickfix list
:call setqflist([], 'a', {'nr' : 4, 'title' : 'SomeTitle'})

" create a new quickfix list at the end of the stack
:call setqflist([], ' ', {'nr' : '$',
                    \ 'lines' : systemlist('grep -Hn class *.java')})

" create a new location list from a command output
:call setloclist(0, [], ' ', {'lines' : systemlist('grep -Hn main *.c')})

" replace the location list entries for the third window
:call setloclist(3, [], 'r', {'items' : newItems})
```

3. Using more than one list of errors quickfix-error-lists

So far it has been assumed that there is only one list of errors. Actually there can be multiple used lists that are remembered; see 'chistory' and 'lhistory'.
When starting a new list, the previous ones are automatically kept. Two commands can be used to access older error lists. They set one of the existing error lists as the current one.

:colder :col E380
:col[der] [count] Go to older error list. When [count] is given, do this [count] times. When already at the oldest error list, an error message is given.

:lolder :lol
:lol[der] [count] Same as :colder, except use the location list for the current window instead of the quickfix list.

:cnewer :cnew E381
:cnew[er] [count] Go to newer error list. When [count] is given, do this [count] times. When already at the newest error list, an error message is given.

:lnewer :lnew
:lnew[er] [count] Same as :cnewer, except use the location list for the current window instead of the quickfix list.

:chistory :chi
:[count]chi[story] Show the list of error lists. The current list is marked with ">". The output looks like:

```
  error list 1 of 3; 43 errors   :make
> error list 2 of 3; 0 errors    :helpgrep tag
  error list 3 of 3; 15 errors   :grep ex_help *.c
```

When [count] is given, then the count'th quickfix list is made the current list. Example:

```
" Make the 4th quickfix list current
:4chistory
```

:lhistory :lhi
:[count]lhi[story] Show the list of location lists, otherwise like :chistory.

When adding a new error list, it becomes the current list.

When ":colder" has been used and ":make" or ":grep" is used to add a new error list, one newer list is overwritten. This is especially useful if you are browsing with ":grep" grep. If you want to keep the more recent error lists, use ":cnewer 99" first.

To get the number of lists in the quickfix and location list stack, you can use the getqflist() and getloclist() functions respectively with the list number set to the special value '$'. Examples:

```
echo getqflist({'nr' : '$'}).nr
echo getloclist(3, {'nr' : '$'}).nr
```

To get the number of the current list in the stack:

```
echo getqflist({'nr' : 0}).nr
```

4. Using :make

:make_makeprg

:mak :make

:mak[e][!] [arguments] 1. All relevant QuickFixCmdPre autocommands are executed.

1. If the 'autowrite' option is on, write any changed buffers
2. An errorfile name is made from 'makeef'. If 'makeef' doesn't contain "##", and a file with this name already exists, it is deleted.
3. The program given with the 'makeprg' option is started (default "make") with the optional [arguments] and the output is saved in the errorfile (for Unix it is also echoed on the screen).
4. The errorfile is read using 'errorformat'.
5. All relevant QuickFixCmdPost autocommands are executed. See example below.
6. If [!] is not given the first error is jumped to.
7. The errorfile is deleted.
8. You can now move through the errors with commands like :cnext and :cprevious, see above.

This command does not accept a comment, any " characters are considered part of the arguments. If the encoding of the program output differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:lmak :lmake

:lmak[e][!] [arguments]
Same as ":make", except the location list for the current window is used instead of the quickfix list.

In short, :make runs 'makeprg', reads its output using 'errorformat', optionally jumps to the first recognized error, and then removes the temporary error file used by the normal :make workflow. If 'shellpipe' is empty, or if the program manages its own output file, this cleanup does not apply to that program's file. Use :cnext and related commands to move through the resulting list.

The ":make" command executes the command given with the 'makeprg' option. This is done by passing the command to the shell given with the 'shell' option. This works almost like typing

":!{makeprg} [arguments] {shellpipe} {errorfile}".

{makeprg} is the string given with the 'makeprg' option. Any command can be used, not just "make". Characters '%' and '#' are expanded as usual on a command-line. You can use "%<" to insert the current file name without extension, or "#<" to insert the alternate file name without extension, for example:

```
:set makeprg=make\ #<.o
```

[arguments] is anything that is typed after ":make".
{shellpipe} is the 'shellpipe' option.
{errorfile} is the 'makeef' option, with ## replaced to make it unique.

The placeholder "$*" can be used for the argument list in {makeprg} if the command needs some additional characters after its arguments. The $* is replaced then by all arguments. Example:

```
:set makeprg=latex\ \\\\nonstopmode\ \\\\input\\{$*}
```

or simpler

```
:let &mp = 'latex \\nonstopmode \\input\{$*}'
```

"$*" can be given multiple times, for example:

```
:set makeprg=gcc\ -o\ $*\ $*
```

The 'shellpipe' option defaults to "2>&1| tee" for Win32.
This means that the output of the compiler is saved in a file and not shown on the screen directly. For Unix "| tee" is used. The compiler output is shown on the screen and saved in a file the same time. Depending on the shell used "|& tee" or "2>&1| tee" is the default, so stderr output will be included.

If 'shellpipe' is empty, the {errorfile} part will be omitted. This is useful for compilers that write to an errorfile themselves.

Using QuickFixCmdPost to fix the encoding

It may be that 'encoding' is set to an encoding that differs from the messages your build program produces. This example shows how to fix this after Vim has read the error messages:

```
function QfMakeConv()
   let qflist = getqflist()
   for i in qflist
      let i.text = iconv(i.text, "cp936", "utf-8")
   endfor
   call setqflist(qflist)
endfunction

au QuickFixCmdPost make call QfMakeConv()
```

(Example by Faque Cheng)
Another option is using 'makeencoding'.

5. Using :vimgrep and :grep

grep lid

Vim has two ways to find matches for a pattern: internal and external. The advantage of the internal grep is that it works on all systems and uses the powerful Vim search patterns. An external grep program can be used when the Vim grep does not do what you want.

The internal method will be slower, because files are read into memory. For large projects, consider using :grep with an external search program. The advantages of the internal method are:

- Line separators and encoding are automatically recognized, as if a file is being edited.
- Uses Vim search patterns. Multi-line patterns can be used.
- When plugins are enabled: compressed and remote files can be searched.

gzip netrw

To be able to do this Vim loads each file as if it is being edited. When there is no match in the file the associated buffer is wiped out again. The 'hidden' option is ignored here to avoid running out of memory or file descriptors when searching many files. However, when the :hide command modifier is used the buffers are kept loaded. This makes following searches in the same files a lot faster.

Note that :copen (or :lopen for :lgrep) may be used to open a buffer containing the search results in linked form. The :silent command may be used to suppress the default full screen grep output. The ":grep!" form of the :grep command doesn't jump to the first match automatically. These commands can be combined to create a NewGrep command:

```
command! -nargs=+ NewGrep execute 'silent grep! <args>' | copen 42
```

5.1 Using Vim's internal grep

:vim :vimgrep E682 E683

:vim[grep][!] /{pattern}/[g][j][f] {file} ...
Search for {pattern} in the files {file} ... and set the error list to the matches. Files matching 'wildignore' are ignored; files in 'suffixes' are searched last.

{pattern} is a Vim search pattern. Instead of enclosing it in / any non-ID character (see 'isident') can be used, so long as it does not appear in {pattern}.
'ignorecase' applies. To overrule it put /\c in the pattern to ignore case or /\C to match case.
'smartcase' is not used.
If {pattern} is empty (e.g. // is specified), the last used search pattern is used. last-pattern

Flags:
'g' Without the 'g' flag each line is added only once. With 'g' every match is added.

'j' Without the 'j' flag Vim jumps to the first match. With 'j' only the quickfix list is updated. With the [!] any changes in the current buffer are abandoned.

'f' When the 'f' flag is specified, fuzzy string matching is used to find matching lines. The characters in {pattern} must appear in order, but need not be next to each other. In this case, {pattern} is treated as a literal string instead of a regular expression. See fuzzy-matching for more information about fuzzy matching strings.

QuickFixCmdPre and QuickFixCmdPost are triggered.
A file that is opened for matching may use a buffer number, but it is reused if possible to avoid consuming buffer numbers.

:{count}vim[grep] ...
When a number is put before the command this is used as the maximum number of matches to find. Use ":1vimgrep pattern file" to find only the first.
Useful if you only want to check if there is a match and quit quickly when it's found.

Every second or so the searched file name is displayed to give you an idea of the progress made.
Examples:

```
:vimgrep /an error/ *.c
:vimgrep /\<FileName\>/ *.h include/*
:vimgrep /myfunc/ **/*.c
```

For the use of "**" see starstar-wildcard.

:vim[grep][!] {pattern} {file} ...
Like above, but instead of enclosing the pattern in a non-ID character use a white space separated pattern. The pattern must start with an ID character.
Example:

```
:vimgrep Error *.c
```

:lv :lvimgrep
:lv[imgrep][!] /{pattern}/[g][j][f] {file} ...
:lv[imgrep][!] {pattern} {file} ...
Same as ":vimgrep", except the location list for the current window is used instead of the quickfix list.

:vimgrepa :vimgrepadd
:vimgrepa[dd][!] /{pattern}/[g][j][f] {file} ...
:vimgrepa[dd][!] {pattern} {file} ...
Just like ":vimgrep", but instead of making a new list of errors the matches are appended to the current list.

:lvimgrepa :lvimgrepadd
:lvimgrepa[dd][!] /{pattern}/[g][j][f] {file} ...
:lvimgrepa[dd][!] {pattern} {file} ...
Same as ":vimgrepadd", except the location list for the current window is used instead of the quickfix list.

5.2 External grep

Vim can interface with "grep" and grep-like programs (such as the GNU id-utils) in a similar way to its compiler integration (see :make above).

[Unix trivia: The name for the Unix "grep" command comes from ":g/re/p", where "re" stands for Regular Expression.]

:gr :grep
:gr[ep][!] [arguments] Just like ":make", but use 'grepprg' instead of 'makeprg' and 'grepformat' instead of 'errorformat'.
When 'grepprg' is "internal" this works like :vimgrep. Note that the pattern needs to be enclosed in separator characters then.
If the encoding of the program output differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:lgr :lgrep
:lgr[ep][!] [arguments] Same as ":grep", except the location list for the

current window is used instead of the quickfix list.

:grepa :grepadd

:grepa[dd][!] [arguments]
Just like ":grep", but instead of making a new list of errors the matches are appended to the current list. Example:

```
:call setqflist([])
:bufdo grepadd! something %
```

The first command makes a new error list which is empty. The second command executes "grepadd" for each listed buffer. Note the use of ! to avoid that ":grepadd" jumps to the first error, which is not allowed with :bufdo.
An example that uses the argument list and avoids errors for files without matches:

```
:silent argdo try
  \ | grepadd! something %
  \ | catch /E480:/
  \ | endtry"
```

If the encoding of the program output differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:lgrepa :lgrepadd

:lgrepa[dd][!] [arguments]
Same as ":grepadd", except the location list for the current window is used instead of the quickfix list.

5.3 Setting up external grep

If you have a standard "grep" program installed, the :grep command may work well with the defaults. The syntax is very similar to the standard command:

```
:grep foo *.c
```

Will search all files with the .c extension for the substring "foo". The arguments to :grep are passed straight to the "grep" program, so you can use whatever options your "grep" supports.

By default, :grep invokes grep with the -n option (show file and line numbers). You can change this with the 'grepprg' option. You will need to set 'grepprg' if:

a) You are using a program that isn't called "grep"
b) You have to call grep with a full path
c) You want to pass other options automatically (e.g. case insensitive search.)

Once "grep" has executed, Vim parses the results using the 'grepformat' option. This option works in the same way as the 'errorformat' option - see that for details. You may need to change 'grepformat' from the default if your grep outputs in a non-standard format, or you are using some other program with a special format.

Once the results are parsed, Vim loads the first file containing a match and jumps to the appropriate line, in the same way that it jumps to a compiler error in quickfix mode. You can then use the :cnext, :clist, etc. commands to see the other matches.

5.4 Using :grep with id-utils

You can set up :grep to work with the GNU id-utils like this:

```
:set grepprg=lid\ -Rgrep\ -s
:set grepformat=%f:%l:%m
```

then

```
:grep (regexp)
```

works just as you'd expect.
(provided you remembered to mkid first :)

5.5 Browsing source code with :vimgrep or :grep

Using the stack of error lists that Vim keeps, you can browse your files to look for functions and the functions they call. For example, suppose that you have to add an argument to the read_file() function. You enter this command:

```
:vimgrep /\<read_file\>/ *.c
```

You use ":cn" to go along the list of matches and add the argument. At one place you have to get the new argument from a higher level function msg(), and need to change that one too. Thus you use:

```
:vimgrep /\<msg\>/ *.c
```

While changing the msg() functions, you find another function that needs to
get the argument from a higher level. You can again use ":vimgrep" to find
these functions. Once you are finished with one function, you can use

```
:colder
```

to go back to the previous one.

This works like browsing a tree: ":vimgrep" goes one level deeper, creating a
list of branches. ":colder" goes back to the previous level. You can mix
this use of ":vimgrep" and "colder" to browse all the locations in a tree-like
way. If you do this consistently, you will find all locations without the
need to write down a "todo" list.

6. Selecting a compiler compiler-select

:comp :compiler E666

:comp[iler][!] {name} Set options to work with compiler {name}.
Without the "!" options are set for the
current buffer. With "!" global options are
set.
If you use ":compiler foo" in "file.foo" and
then ":compiler! bar" in another buffer, Vim
will keep on using "foo" in "file.foo".

The Vim plugins in the "compiler" directory will set options to use the
selected compiler. For :compiler local options are set, for :compiler!
global options.

In normal use, select a compiler with :compiler {name} and then run :make.
The compiler plugin usually sets 'makeprg' and 'errorformat' so Vim can run
the compiler and read its messages. The descriptions below document options
for particular compiler plugins.

The values set by a compiler plugin can be changed afterwards with :set or
:setlocal. :compiler {name} sets options for the current buffer, while
:compiler! {name} sets global options; a buffer-local value takes precedence
over a global value.

current_compiler

To support older Vim versions, the plugins always use "current_compiler" and
not "b:current_compiler". What the command actually does is the following:

- Delete the "current_compiler" and "b:current_compiler" variables.
- Define the "CompilerSet" user command. With "!" it does ":set", without "!"
  it does ":setlocal".
- Execute ":runtime! compiler/{name}.{vim,lua}". The plugins are expected to
  set options with "CompilerSet" and set the "current_compiler" variable to the
  name of the compiler.
- Delete the "CompilerSet" user command.
- Set "b:current_compiler" to the value of "current_compiler".
- Without "!" the old value of "current_compiler" is restored.

For writing a compiler plugin, see write-compiler-plugin.

Use the compiler-make plugin to undo the effect of a compiler plugin.

BIOME compiler-biome quickfix-biome

Biome check lints JavaScript, TypeScript, JSX, TSX, JSON, JSONC, HTML, Vue,
Svelte, Astro, CSS, GraphQL and GritQL files.

Commonly used compiler options can be added to 'makeprg' by setting the
b/g:biome_makeprg_params variable. For example (global default is ""):

```
let b:biome_makeprg_params = "--diagnostic-level=error --staged"
```

CPPCHECK quickfix-cppcheck compiler-cppcheck

Use g/b:`c_cppcheck_params` to set cppcheck parameters. The global
settings by default include

- --verbose: Enables verbose output.
- --force: Forces checking of all configurations.

- --inline-suppr: Allows inline suppressions.

- --enable=...: Enables specific checks like warnings, style, performance,

  portability, information, and missing includes.
- -j: Utilizes multiple processors if available, determined by the

  getconf command if available (requires omitting the unusedFunction check)

For C++ files (filetype == 'cpp'), the --language=c++ option is added to ensure Cppcheck treats the file as C++.

If compile_commands.json is present in the current directory, it is added as a --project parameter to the command line. Otherwise, by default the directories in &path are passed as include directories. These can be set by g/b:`c_cppcheck_includes` as a list of -I flags. Tim Pope's vim-apathy plug-in [0] can expand &path. To also append the folders in a git repo use

```
let &l:path = join(systemlist('git ls-tree -d --name-only -r HEAD'), ',')
```

[0] https://github.com/tpope/vim-apathy

DOTNET compiler-dotnet

The .NET CLI compiler outputs both errors and warnings by default. The output may be limited to include only errors, by setting the g:dotnet_errors_only variable to v:true.

The associated project name is included in each error and warning. To suppress the project name, set the g:dotnet_show_project_file variable to v:false.

Example: limit output to only display errors, and suppress the project name:

```
let dotnet_errors_only = v:true
let dotnet_show_project_file = v:false
compiler dotnet
```

GCC quickfix-gcc compiler-gcc

There's one variable you can set for the GCC compiler:

g:compiler_gcc_ignore_unmatched_lines
Ignore lines that don't match any patterns defined for GCC. Useful if output from commands run from make are generating false positives.

JAVAC compiler-javac

Commonly used compiler options can be added to 'makeprg' by setting the b/g:javac_makeprg_params variable. For example:

```
let g:javac_makeprg_params = "-Xlint:all -encoding utf-8"
```

MAVEN compiler-maven

Commonly used compiler options can be added to 'makeprg' by setting the b/g:maven_makeprg_params variable. For example:

```
let g:maven_makeprg_params = "-DskipTests -U -X"
```

SPOTBUGS compiler-spotbugs

SpotBugs is a static analysis tool that can be used to find bugs in Java. It scans the Java bytecode of all classes in the currently open buffer. (Therefore, :compiler! spotbugs is not supported.)

Commonly used compiler options can be added to 'makeprg' by setting the "b:" or "g:spotbugs_makeprg_params" variable. For example:

```
let b:spotbugs_makeprg_params = "-longBugCodes -effort:max -low"
```

The global default is "-workHard -experimental".

By default, the class files are searched in the directory where the source files are placed. However, typical Java projects use distinct directories for source files and class files. To make both known to SpotBugs, assign their paths (distinct and relative to their common root directory) to the following properties (using the example of a common Maven project):

```
let g:spotbugs_properties = {
        \ 'sourceDirPath':      ['src/main/java'],
        \ 'classDirPath':       ['target/classes'],
        \ 'testSourceDirPath':  ['src/test/java'],
        \ 'testClassDirPath':   ['target/test-classes'],
\ }
```

Note that source and class path entries are expected to come in pairs: define
both "sourceDirPath" and "classDirPath" when you are considering at least one,
and apply the same logic to "testSourceDirPath" and "testClassDirPath".
Note that values for the path keys describe only for SpotBugs where to look
for files; refer to the documentation for particular compiler plugins for more
information.

The default pre- and post-compiler actions are provided for Ant, Maven, and
Javac compiler plugins and can be selected by assigning the name of a compiler
plugin (ant, maven, or javac) to the "compiler" key:

```
let g:spotbugs_properties = {
        \ 'compiler':           'maven',
\ }
```

This single setting is essentially equivalent to all the settings below, with
the exception made for the "PreCompilerAction" and "PreCompilerTestAction"
values: their listed Funcrefs will obtain no-op implementations whereas the
implicit Funcrefs of the "compiler" key will obtain the requested defaults if
available.

```
let g:spotbugs_properties = {
        \ 'PreCompilerAction':
                \ function('spotbugs#DefaultPreCompilerAction'),
        \ 'PreCompilerTestAction':
                \ function('spotbugs#DefaultPreCompilerTestAction'),
        \ 'PostCompilerAction':
                \ function('spotbugs#DefaultPostCompilerAction'),
        \ 'sourceDirPath':      ['src/main/java'],
        \ 'classDirPath':       ['target/classes'],
        \ 'testSourceDirPath':  ['src/test/java'],
        \ 'testClassDirPath':   ['target/test-classes'],
\ }
```

With default actions, the compiler of choice will attempt to rebuild the class
files for the buffer (and possibly for the whole project) as soon as a Java
syntax file is loaded; then, spotbugs will attempt to analyze the quality of
the compilation unit of the buffer.

Vim commands proficient in 'makeprg' [0] can be composed with default actions.
Begin by considering which of the supported keys, "DefaultPreCompilerCommand",
"DefaultPreCompilerTestCommand", or "DefaultPostCompilerCommand", you need to
write an implementation for, observing that each of these keys corresponds to
a particular "*Action" key. Follow it by defining a new function that always
declares an only parameter of type string and puts to use a command equivalent
of :make, and assigning its Funcref to the selected key. For example:

```
function! GenericPostCompilerCommand(arguments) abort
        execute 'make ' .. a:arguments
endfunction

let g:spotbugs_properties = {
        \ 'DefaultPostCompilerCommand':
                \ function('GenericPostCompilerCommand'),
\ }
```

When "PostCompilerAction" is available, "PostCompilerActionExecutor" is also
supported. Its value must be a Funcref pointing to a function that always
declares a single parameter of type string and decides whether :execute can
be dispatched on its argument, containing a pending post-compiler action,
after ascertaining the current status of :cc (or :ll):

```
function! GenericPostCompilerActionExecutor(action) abort
        try
                cc
        catch /\<E42:/
                execute a:action
        endtry
endfunction
```

Complementary, some or all of the available "Pre*Action"s (or "*Pre*Command"s)
may run :doautocmd java_spotbugs_post User in their implementations before
:make (or its equivalent) to define a once-only ShellCmdPost :autocmd

that will arrange for "PostCompilerActionExecutor" to be invoked; and then run
:doautocmd java_spotbugs_post ShellCmdPost to consume this event:

```
function! GenericPreCompilerCommand(arguments) abort
        if !exists('g:spotbugs_compilation_done')
                doautocmd java_spotbugs_post User
                execute 'make ' .. a:arguments
                " only run doautocmd when :make was synchronous
                " see note below
                doautocmd java_spotbugs_post ShellCmdPost " XXX: (a)
                let g:spotbugs_compilation_done = 1
        else
                cc
        endif
endfunction

function! GenericPreCompilerTestCommand(arguments) abort
        if !exists('g:spotbugs_test_compilation_done')
                doautocmd java_spotbugs_post User
                execute 'make ' .. a:arguments
                " only run doautocmd when :make was synchronous
                " see note below
                doautocmd java_spotbugs_post ShellCmdPost " XXX: (b)
                let g:spotbugs_test_compilation_done = 1
        else
                cc
        endif
endfunction

let g:spotbugs_properties = {
        \ 'compiler':           'maven',
        \ 'DefaultPreCompilerCommand':
                \ function('GenericPreCompilerCommand'),
        \ 'DefaultPreCompilerTestCommand':
                \ function('GenericPreCompilerTestCommand'),
        \ 'PostCompilerActionExecutor':
                \ function('GenericPostCompilerActionExecutor'),
\ }
```

If a command equivalent of :make is capable of asynchronous execution and
consuming ShellCmdPost events, :doautocmd java_spotbugs_post ShellCmdPost
must be removed from such "*Action" (or "*Command") implementations (i.e. the
lines (a) and (b) in the listed examples) to retain a sequential order for
non-blocking execution, and any notification (see below) must be suppressed.
A ShellCmdPost :autocmd can be associated with any :augroup by assigning
its name to the "augroupForPostCompilerAction" key.

When default actions are not suited to a desired workflow, proceed by writing
arbitrary functions yourself and matching their Funcrefs to the supported
keys: "PreCompilerAction", "PreCompilerTestAction", and "PostCompilerAction".

The next example re-implements the default pre-compiler actions for a Maven
project and requests other default Maven settings with the "compiler" entry:

```
function! MavenPreCompilerAction() abort
        call spotbugs#DeleteClassFiles()
        compiler maven
        make compile
        cc
endfunction

function! MavenPreCompilerTestAction() abort
        call spotbugs#DeleteClassFiles()
        compiler maven
        make test-compile
        cc
endfunction

let g:spotbugs_properties = {
        \ 'compiler':           'maven',
        \ 'PreCompilerAction':
                \ function('MavenPreCompilerAction'),
        \ 'PreCompilerTestAction':
                \ function('MavenPreCompilerTestAction'),
\ }
```

Note that all entered custom settings will take precedence over the matching
default settings in "g:spotbugs_properties".
Note that it is necessary to notify the plugin of the result of a pre-compiler
action before further work can be undertaken. Using :cc after :make (or
:ll after :lmake) as the last command of an action is the supported means
of such communication.

Two commands, "SpotBugsRemoveBufferAutocmd" and "SpotBugsDefineBufferAutocmd",
are provided to toggle actions for buffer-local autocommands. For example, to
also run actions on any BufWritePost and Signal event, add these lines to
~/.config/nvim/after/ftplugin/java.vim:

```
if exists(':SpotBugsDefineBufferAutocmd') == 2
        SpotBugsDefineBufferAutocmd BufWritePost Signal
endif
```

Otherwise, you can turn to :doautocmd java_spotbugs User at any time.

The "g:spotbugs_properties" variable is consulted by the Java filetype plugin (ft-java-plugin) to arrange for the described automation, and, therefore, it must be defined before FileType events can take place for the buffers loaded with Java source files. It could, for example, be set in a project-local vimrc loaded by [1].

Both "g:spotbugs_properties" and "b:spotbugs_properties" are recognized and must be modifiable (:unlockvar). The "*Command" entries are always treated as global functions to be shared among all Java buffers.

The SpotBugs Java library and, by extension, its distributed shell scripts do not support in the -textui mode listed pathnames with directory filenames that contain blank characters [2]. To work around this limitation, consider making a symbolic link to such a directory from a directory that does not have blank characters in its name and passing this information to SpotBugs:

```
let g:spotbugs_alternative_path = {
        \ 'fromPath':   'path/to/dir_without_blanks',
        \ 'toPath':     'path/to/dir with blanks',
\ }
```

[1] https://github.com/MarcWeber/vim-addon-local-vimrc
[2] https://github.com/spotbugs/spotbugs/issues/909

GNU MAKE compiler-make

Since the default make program is "make", the compiler plugin for make, :compiler make, will reset the 'makeprg' and 'errorformat' option to the default values and unlet any variables that may have been set by a previous compiler plugin.

GROFF quickfix-groff compiler-groff

The GROFF compiler plugin uses the mom macro set (documented in the groff_mom manpage) as input and expects that the output file type extension is passed to make, say :make html or :make pdf.

Additional arguments can be passed to groff by setting them in b:groff_compiler_args or g:groff_compiler_args. The language argument passed to groff is set using 'spelllang'; it can be overridden by setting b:groff_compiler_lang. The default encoding is UTF-8 and can be changed by setting b:groff_compiler_encoding or g:groff_compiler_encoding.

PANDOC quickfix-pandoc compiler-pandoc

The Pandoc compiler plugin expects that an output file type extension is passed to make, say :make html or :make pdf.

Additional arguments can be passed to pandoc:

- either by appending them to make, say :make html --self-contained .

- or setting them in b:pandoc_compiler_args or g:pandoc_compiler_args.

The --from argument is an educated guess using the buffer file type;
it can be overridden by setting b:pandoc_compiler_from.
The --metadata lang argument is set using 'spelllang';
If --from=markdown is assumed and no title set in a title header or
YAML block, then the filename (without extension) is used as the title.

PERL quickfix-perl compiler-perl

The Perl compiler plugin doesn't actually compile, but invokes Perl's internal syntax checking feature and parses the output for possible errors so you can correct them in quick-fix mode.

Warnings are forced regardless of "no warnings" or "$^W = 0" within the file being checked. To disable this set g:perl_compiler_force_warnings to a zero value. For example:

```
let g:perl_compiler_force_warnings = 0
```

MYPY TYPE CHECKER compiler-mypy

Commonly used compiler options can be added to 'makeprg' by setting the b/g:mypy_makeprg_params variable. For example:

```
let b:mypy_makeprg_params = "--warn-unused-ignores"
```

The global default is "--strict --ignore-missing-imports".

PYRIGHT TYPE CHECKER

compiler-pyright

Commonly used compiler options can be added to 'makeprg' by setting the
b/g:pyright_makeprg_params variable.

The global default is "pyright".

TY TYPE CHECKER

compiler-ty

Commonly used compiler options and executable can be set by the
b/g:ty_makeprg variable. For example:

```
let b:ty_makeprg = "uv run ty"
```

The global default is "ty --no-progress --color=never".

RUFF LINTER

compiler-ruff

Commonly used compiler options can be added to 'makeprg' by setting the
b/g:ruff_makeprg_params variable. For example:

```
let b:ruff_makeprg_params = "--max-line-length "..&textwidth
```

The global default is "--preview".

PYLINT LINTER

compiler-pylint

Commonly used compiler options can be added to 'makeprg' by setting the
b/g:pylint_makeprg_params variable. For example:

```
let b:pylint_makeprg_params = "--max-line-length "..&textwidth
```

The global default is "--jobs=0" to use (almost) all cores.

PYUNIT COMPILER

compiler-pyunit

This is not actually a compiler, but a unit testing framework for the
Python language. It is included into standard Python distribution
starting from version 2.0. For older versions, you can get it from
https://pyunit.sourceforge.net.

When you run your tests with the help of the framework, possible errors
are parsed by Vim and presented for you in quick-fix mode.

Unfortunately, there is no standard way to run the tests.
The alltests.py script seems to be used quite often, that's all.
Useful values for the 'makeprg' options therefore are:
```
 setlocal makeprg=./alltests.py " Run a testsuite
 setlocal makeprg=python\ %:S   " Run a single testcase
```

PYTEST COMPILER

compiler-pytest

Commonly used compiler options can be added to 'makeprg' by setting the
b/g:pytest_makeprg_params variable. For example:

```
let b:pytest_makeprg_params = "--verbose --no-summary --disable-warnings"
```

The global default is "--tb=short --quiet"; Python warnings are suppressed.

TEX COMPILER

compiler-tex

Included in the distribution compiler for TeX ($VIMRUNTIME/compiler/tex.vim)
uses make command if possible. If the compiler finds a file named "Makefile"
or "makefile" in the current directory, it supposes that you want to process
your *TeX files with make, and the makefile does the right work. In this case
compiler sets 'errorformat' for *TeX output and leaves 'makeprg' untouched.
If neither "Makefile" nor "makefile" is found, the compiler will not use make.
You can force the compiler to ignore makefiles by defining
b:tex_ignore_makefile or g:tex_ignore_makefile variable (they are checked for
existence only).

If the compiler chose not to use make, it needs to choose a right program for
processing your input. If b:tex_flavor or g:tex_flavor (in this precedence)
variable exists, it defines TeX flavor for :make (actually, this is the name
of executed command), and if both variables do not exist, it defaults to
"latex". For example, while editing chapter2.tex \input-ed from mypaper.tex
written in AMS-TeX:

```
:let b:tex_flavor = 'amstex'
:compiler tex
```

```
        [editing...]
```

```
:make mypaper
```

Note that you must specify a name of the file to process as an argument (to process the right file when editing \input-ed or \include-ed file; portable solution for substituting % for no arguments is welcome). This is not in the semantics of make, where you specify a target, not source, but you may specify filename without extension ".tex" and mean this as "make filename.dvi or filename.pdf or filename.some_result_extension according to compiler".

Note: tex command line syntax is set to usable both for MikTeX (suggestion by Srinath Avadhanula) and teTeX (checked by Artem Chuprina). Suggestion from errorformat-LaTeX is too complex to keep it working for different shells and OSes and also does not allow to use other available TeX options, if any. If your TeX doesn't support "-interaction=nonstopmode", please report it with different means to express \nonstopmode from the command line.

TOMBI quickfix-toml compiler-tombi

The tombi compiler plugin does not compile.

It runs "tombi lint" and parses diagnostics into the quickfix list.

Color codes are stripped from the linter output to keep errorformat parsing reliable. This may require a working "sed" for old versions of the tombi linter.

TSC COMPILER compiler-tsc

The executable and compiler options can be added to 'makeprg' by setting the b/g:tsc_makeprg variable. For example:

```
let b:tsc_makeprg = "npx tsc --noEmit"
```

TYPST COMPILER compiler-typst

Vim includes a compiler plugin for Typst files. This compiler is enabled automatically in Typst buffers by the Typst filetype plugin ft-typst-plugin. Run :make to compile the current Typst file.

g:typst_cmd

By default Vim will use "typst" as the command to run the Typst compiler. This can be changed by setting the g:typst_cmd variable:

```
let g:typst_cmd = "/path/to/other/command"
```

7. The error format error-file-format

errorformat E372 E373 E374 E375 E376 E377 E378

The 'errorformat' option specifies patterns that Vim uses to read compiler output. A pattern can extract the file name, line number, column and message from each line. The first format that matches with an error message is used. You can add several formats for different messages your compiler produces, or even entries for multiple compilers. See efm-entries.

Each entry in 'errorformat' is a scanf-like string that describes the format. First, you need to know how scanf works. Look in the documentation of your C compiler. Below you find the % items that Vim understands. Others are invalid.

Quick start: Vim already includes formats for many common compilers. Check errorformats for an example before writing your own. If no example matches, start with the basic items below and adapt one of the examples as needed.

Special characters in 'errorformat' are comma and backslash. See efm-entries for how to deal with them. Note that a literal "%" is matched by "%%", thus it is not escaped with a backslash.
Keep in mind that in the :make and :grep output all NUL characters are replaced with SOH (0x01).

Note: By default the difference between upper and lowercase is ignored. If you want to match case, add "\C" to the pattern /\C.

Vim will read lines of any length, but only the first 4095 bytes are used, the rest is ignored. Items can only be 1023 bytes long.

Basic items

%f	file name (finds a string)
%b	buffer number (finds a number)
%o	module name (finds a string)
%l	line number (finds a number)
%e	end line number (finds a number)
%c	column number (finds a number representing character column of the error, byte index, a <tab> is 1 character column)
%v	virtual column number (finds a number representing the screen column of the error, where a <tab> is always 8 screen columns regardless of 'tabstop')
%k	end column number (finds a number representing the character column of the error, byte index, or a number representing screen end column of the error if

```
                    it's used with %v)
        %t          error type (finds a single character):
                        e - error message
                        w - warning message
                        i - info message
                        n - note message
                    The uppercase letters E, W, I and N are also
                    recognized and have the same meaning.
        %n          error number (finds a number)
        %m          error message (finds a string)
        %r          matches the "rest" of a single-line file message %O/P/Q
        %p          pointer line (finds a sequence of '-', '.', ' ' or
                    tabs and uses the length for the column number)
        %*{conv}    any scanf non-assignable conversion
        %%          the single '%' character
        %s          search text (finds a string)
```

The "%f" conversion may depend on the current 'isfname' setting. "~/" is expanded to the home directory and environment variables are expanded.

The "%f" and "%m" conversions have to detect the end of the string. This normally happens by matching following characters and items. When nothing is following the rest of the line is matched. If "%f" is followed by a '%' or a backslash, it will look for a sequence of 'isfname' characters.

On Windows a leading "C:" will be included in "%f", even when using "%f:". This means that a file name which is a single alphabetical letter will not be detected.

The "%b" conversion is used to parse a buffer number. This is useful for referring to lines in a scratch buffer or a buffer with no name. If a buffer with the matching number doesn't exist, then that line is used as a non-error line.

The "%p" conversion is normally followed by a "^". It's used for compilers that output a line like:

```
^
```

or

```
---------^
```

to indicate the column of the error. This is to be used in a multi-line error message. See errorformat-javac for a useful example.

The "%s" conversion specifies the text to search for, to locate the error line. The text is used as a literal string. The anchors "^" and "$" are added to the text to locate the error line exactly matching the search text and the text is prefixed with the "\V" atom to make it "very nomagic". The "%s" conversion can be used to locate lines without a line number in the error output. Like the output of the "grep" shell command.
When the pattern is present the line number will not be used.

The "%o" conversion specifies the module name in quickfix entry. If present it will be used in quickfix error window instead of the filename. The module name is used only for displaying purposes, the file name is used when jumping to the file.

Changing directory

The following uppercase conversion characters specify the type of special format strings. At most one of them may be given as a prefix at the beginning of a single comma-separated format pattern.
Some compilers produce messages that consist of directory names that have to be prepended to each file name read by %f (example: GNU make). The following codes can be used to scan these directory names; they will be stored in an internal directory stack. E379

```
        %D          "enter directory" format string; expects a following
                      %f that finds the directory name
        %X          "leave directory" format string; expects following %f
```

When defining an "enter directory" or "leave directory" format, the "%D" or "%X" has to be given at the start of that substring. Vim tracks the directory changes and prepends the current directory to each erroneous file found with a relative path. See quickfix-directory-stack for details, tips and limitations.

Multi-line messages errorformat-multi-line

It is possible to read the output of programs that produce multi-line messages, i.e. error strings that consume more than one line. Possible prefixes are:

```
        %E          start of a multi-line error message
        %W          start of a multi-line warning message
        %I          start of a multi-line informational message
        %N          start of a multi-line note message
        %A          start of a multi-line message (unspecified type)
        %>          for next line start with current pattern again efm-%>
        %C          continuation of a multi-line message
        %Z          end of a multi-line message
```

These can be used with '+' and '-', see efm-ignore below.

Using "\n" in the pattern won't work to match multi-line messages.

Example: Your compiler happens to write out errors in the following format
(leading line numbers not being part of the actual output):

1 Error 275
2 line 42
3 column 3
4 ' ' expected after '--'

The appropriate error format string has to look like this:

```
:set efm=%EError\ %n,%Cline\ %l,%Ccolumn\ %c,%Z%m
```

And the :clist error message generated for this error is:

```
 1:42 col 3 error 275:  ' ' expected after '--'
```

Another example: Think of a Python interpreter that produces the following
error message (line numbers are not part of the actual output):

```
 1  ======================================================================
 2  FAIL: testGetTypeIdCachesResult (dbfacadeTest.DjsDBFacadeTest)
 3  ----------------------------------------------------------------------
 4  Traceback (most recent call last):
 5    File "unittests/dbfacadeTest.py", line 89, in testFoo
 6      self.assertEquals(34, dtid)
 7    File "/usr/lib/python3.8/unittest.py", line 286, in
 8   failUnlessEqual
 9      raise self.failureException, \
10  AssertionError: 34 != 33
11
12  ----------------------------------------------------------------------
13  Ran 27 tests in 0.063s
```

Say you want :clist write the relevant information of this message only,
namely:

```
 5 unittests/dbfacadeTest.py:89:  AssertionError: 34 != 33
```

Then the error format string could be defined as follows:

```
:set efm=%C\ %.%#,%A\ \ File\ \"%f\"\\,\ line\ %l%.%#,%Z%[%^\ ]%\\@=%m
```

Note that the %C string is given before the %A here: since the expression
' %.%#' (which stands for the regular expression ' .*') matches every line
starting with a space, followed by any characters to the end of the line,
it also hides line 7 which would trigger a separate error message otherwise.
Error format strings are always parsed pattern by pattern until the first
match occurs.

efm-%>

The %> item can be used to avoid trying patterns that appear earlier in
'errorformat'. This is useful for patterns that match just about anything.
For example, if the error looks like this:

```
Error in line 123 of foo.c:
unknown variable "i"
```

This can be found with:

```
:set efm=xxx,%E%>Error in line %l of %f:,%Z%m
```

Where "xxx" has a pattern that would also match the second line.

Important: There is no memory of what part of the errorformat matched before;
every line in the error file gets a complete new run through the error format
lines. For example, if one has:

```
setlocal efm=aa,bb,cc,dd,ee
```

Where aa, bb, etc. are error format strings. Each line of the error file will
be matched to the pattern aa, then bb, then cc, etc. Just because cc matched
the previous error line does _not_ mean that dd will be tried first on the
current line, even if cc and dd are multi-line errorformat strings.

Separate file name errorformat-separate-filename

These prefixes are useful if the file name is given once and multiple messages
follow that refer to this file name.

```
        %O              single-line file message: overread the matched part
        %P              single-line file message: push file %f onto the stack
        %Q              single-line file message: pop the last file from stack
```

Example: Given a compiler that produces the following error logfile (without
leading line numbers):

```
 1  [a1.tt]
 2  (1,17)  error: ';' missing
 3  (21,2)  warning: variable 'z' not defined
 4  (67,3)  error: end of file found before string ended
 5
 6  [a2.tt]
 7
 8  [a3.tt]
```

```
     9  NEW compiler v1.1
    10  (2,2)   warning: variable 'x' not defined
    11  (67,3)  warning: 's' already defined
```

This logfile lists several messages for each file enclosed in [...] which are
properly parsed by an error format like this:

```
:set efm=%+P[%f],(%l\\,%c)%*[\ ]%t%*[^:]:\ %m,%-Q
```

A call of :clist writes them accordingly with their correct filenames:

```
  2 a1.tt:1 col 17 error: ';' missing
  3 a1.tt:21 col 2 warning: variable 'z' not defined
  4 a1.tt:67 col 3 error: end of file found before string ended
  8 a3.tt:2 col 2 warning: variable 'x' not defined
  9 a3.tt:67 col 3 warning: 's' already defined
```

Unlike the other prefixes that all match against whole lines, %P, %Q and %O
can be used to match several patterns in the same line. Thus it is possible
to parse even nested files like in the following line:

```
{"file1" {"file2" error1} error2 {"file3" error3 {"file4" error4 error5}}}
```

The %O then parses over strings that do not contain any push/pop file name
information. See errorformat-LaTeX for an extended example.

Ignoring and using whole messages efm-ignore

The codes '+' or '-' can be combined with the uppercase codes above; in that
case they have to precede the letter, e.g. '%+A' or '%-G':

%-	do not include the matching multi-line in any output
%+	include the whole matching line in the %m error string

One prefix is only useful in combination with '+' or '-', namely %G. It
parses over lines containing general information like compiler version strings
or other headers that can be skipped.

%-G	ignore this message
%+G	general message

Pattern matching

The scanf()-like "%*[]" notation is supported for backward-compatibility
with previous versions of Vim. However, it is also possible to specify
(nearly) any Vim supported regular expression in format strings.
Since meta characters of the regular expression language can be part of
ordinary matching strings or file names (and therefore internally have to
be escaped), meta symbols have to be written with leading '%':

%\	The single '\' character. Note that this has to be escaped ("%\\") in ":set errorformat=" definitions.
%.	The single '.' character.
%#	The single "*"(!) character.
%^	The single '^' character. Note that this is not useful, the pattern already matches start of line.
%$	The single '$' character. Note that this is not useful, the pattern already matches end of line.
%[	The single '[' character for a [] character range.
%~	The single '~' character.

When using character classes in expressions (see /\i for an overview),
terms containing the "\+" quantifier can be written in the scanf() "%*"
notation. Example: "%\\d%\\+" ("\d\+", "any number") is equivalent to
"%*\\d".
Important note: The \(...\) grouping of sub-matches can not be used in format
specifications because it is reserved for internal conversions.

Multiple entries in 'errorformat' efm-entries

To be able to detect output from several compilers, several format patterns
may be put in 'errorformat', separated by commas (note: blanks after the comma
are ignored). The first pattern that has a complete match is used. If no
match is found, matching parts from the last one will be used, although the
file name is removed and the error message is set to the whole message. If
there is a pattern that may match output from several compilers (but not in a
right way), put it after one that is more restrictive.

To include a comma in a pattern precede it with a backslash (you have to type
two in a ":set" command). To include a backslash itself give two backslashes
(you have to type four in a ":set" command). You also need to put a backslash
before a space for ":set".

Valid matches quickfix-valid

If a line does not completely match one of the entries in 'errorformat', the
whole line is put in the error message and the entry is marked "not valid"
These lines are skipped with the ":cn" and ":cp" commands (unless there is
no valid line at all). You can use ":cl!" to display all the error messages.

If the error format does not contain a file name Vim cannot switch to the
correct file. You will have to do this by hand.

For example, the format of the output from the Amiga Aztec compiler is:

```
filename>linenumber:columnnumber:errortype:errornumber:errormessage
```

filename	name of the file in which the error was detected
linenumber	line number where the error was detected
columnnumber	column number where the error was detected
errortype	type of the error, normally a single 'E' or 'W'

```
        errornumber     number of the error (for lookup in the manual)
        errormessage    description of the error
```

This can be matched with this 'errorformat' entry:

```
        %f>%l:%c:%t:%n:%m
```

Some examples for C compilers that produce single-line error outputs:

```
%f:%l:\ %t%*[^0123456789]%n:\ %m        for Manx/Aztec C error messages
                                        (scanf() doesn't understand [0-9])
%f\ %l\ %t%*[^0-9]%n:\ %m               for SAS C
\"%f\"\\,%*[^0-9]%l:\ %m                for generic C compilers
%f:%l:\ %m                              for GCC
%f:%l:\ %m,%Dgmake[%*\\d]:\ Entering\ directory\ `%f',
%Dgmake[%*\\d]:\ Leaving\ directory\ `%f'
                                        for GCC with gmake (concat the lines!)
%f(%l)\ :\ %*[^:]:\ %m                  old SCO C compiler (pre-OS5)
%f(%l)\ :\ %t%*[^0-9]%n:\ %m            idem, with error type and number
%f:%l:\ %m,In\ file\ included\ from\ %f:%l:,\^I\^Ifrom\ %f:%l%m
                                        for GCC, with some extras
```

Extended examples for the handling of multi-line messages are given below, see errorformat-Jikes and errorformat-LaTeX.

Note the backslash in front of a space and double quote. It is required for the :set command. There are two backslashes in front of a comma, one for the :set command and one to avoid recognizing the comma as a separator of error formats.

Filtering messages

If you have a compiler that produces error messages that do not fit in the format string, you could write a program that translates the error messages into this format. You can use this program with the ":make" command by changing the 'makeprg' option. For example:

```
:set mp=make\ \\\|&\ error_filter
```

The backslashes before the pipe character are required to avoid it to be recognized as a command separator. The backslash before each space is required for the set command.

8. The directory stack quickfix-directory-stack

Quickfix maintains a stack for saving all used directories parsed from the make output. For GNU-make this is rather simple, as it always prints the absolute path of all directories it enters and leaves. Regardless if this is done via a 'cd' command in the makefile or with the parameter "-C dir" (change to directory before reading the makefile). It may be useful to use the switch "-w" to force GNU-make to print out the working directory before and after processing.

This matters only when compiler output contains relative file names from multiple directories. If the output does not clearly report directory changes, Vim has to guess and can select the wrong file. Printing absolute directory names and both entering and leaving directory messages avoids this problem.

Maintaining the correct directory is more complicated if you don't use GNU-make. AIX-make for example doesn't print any information about its working directory. Then you need to enhance the makefile. In the makefile of LessTif there is a command which echoes "Making {target} in {dir}". The special problem here is that it doesn't print information on leaving the directory and that it doesn't print the absolute path.

To solve the problem with relative paths and missing "leave directory" messages Vim uses the following algorithm:

1) Check if the given directory is a subdirectory of the current directory.
   If this is true, store it as the current directory.
2) If it is not a subdir of the current directory, try if this is a
   subdirectory of one of the upper directories.
3) If the directory still isn't found, it is assumed to be a subdirectory
   of Vim's current directory.

Additionally it is checked for every file, if it really exists in the identified directory. If not, it is searched in all other directories of the directory stack (NOT the directory subtree!). If it is still not found, it is assumed that it is in Vim's current directory.

There are limitations in this algorithm. These examples assume that make just prints information about entering a directory in the form "Making all in dir".

1) Assume you have following directories and files:
   ./dir1
   ./dir1/file1.c
   ./file1.c

   If make processes the directory "./dir1" before the current directory and there is an error in the file "./file1.c", you will end up with the file "./dir1/file.c" loaded by Vim.

   This can only be solved with a "leave directory" message.

2) Assume you have following directories and files:
   ./dir1

```
./dir1/dir2
./dir2
```

You get the following:

```
Make output                    Directory interpreted by Vim
-----------------------        ----------------------------
Making all in dir1             ./dir1
Making all in dir2             ./dir1/dir2
Making all in dir2             ./dir1/dir2
```

This can be solved by printing absolute directories in the "enter directory" message or by printing "leave directory" messages.

To avoid this problem, ensure to print absolute directory names and "leave directory" messages.

Examples for Makefiles:

Unix:

```
    libs:
            for dn in $(LIBDIRS); do                            \
                (cd $$dn; echo "Entering dir '$$(pwd)'"; make); \
                echo "Leaving dir";                             \
            done
```

Add

```
    %DEntering\ dir\ '%f',%XLeaving\ dir
```

to your 'errorformat' to handle the above output.

Note that Vim doesn't check if the directory name in a "leave directory" messages is the current directory. This is why you could just use the message "Leaving dir".

9. Specific error file formats errorformats

errorformat-Jikes

Jikes(TM), a source-to-bytecode Java compiler published by IBM Research, produces simple multi-line error messages.

An 'errorformat' string matching the produced messages is shown below. The following lines can be placed in the user's init.vim to overwrite Vim's recognized default formats, or see :set+= how to install this format additionally to the default.

```
:set efm=%A%f:%l:%c:%*\\d:%*\\d:,
      \%C%*\\s%trror:%m,
      \%+C%*[^:]%trror:%m,
      \%C%*\\s%tarning:%m,
      \%C%m
```

Jikes(TM) produces a single-line error message when invoked with the option "+E", and can be matched with the following:

```
:setl efm=%f:%l:%v:%*\\d:%*\\d:%*\\s%m
```

errorformat-javac

This 'errorformat' has been reported to work well for javac, which outputs a line with "^" to indicate the column of the error:

```
:setl efm=%A%f:%l:\ %m,%-Z%p^,%-C%.%#
```

or:

```
:setl efm=%A%f:%l:\ %m,%+Z%p^,%+C%.%#,%-G%.%#
```

Here is an alternative from Michael F. Lamb for Unix that filters the errors first:

```
:setl errorformat=%Z%f:%l:\ %m,%A%p^,%-G%*[^sl]%.%#
:setl makeprg=javac\ %:S\ 2>&1\ \\\|\ vim-javac-filter
```

You need to put the following in "vim-javac-filter" somewhere in your path (e.g., in ~/bin) and make it executable:

```
#!/bin/sed -f
/\^$/s/\t/\ /g;/:[0-9]\+:/{h;d};/^[ \t]*\^/G;
```

In English, that sed script:

- Changes single tabs to single spaces and

- Moves the line with the filename, line number, error message to just after

  the pointer line. That way, the unused error text between doesn't break vim's notion of a "multi-line message" and also doesn't force us to include it as a "continuation of a multi-line message."

errorformat-ant

For ant (https://jakarta.apache.org/) the above errorformat has to be modified
to honour the leading [javac] in front of each javac output line:

```
:set efm=%A\ %#[javac]\ %f:%l:\ %m,%-Z\ %#[javac]\ %p^,%-C%.%#
```

The 'errorformat' can also be configured to handle ant together with either
javac or jikes. If you're using jikes, you should tell ant to use jikes' +E
command line switch which forces jikes to generate one-line error messages.
This is what the second line (of a build.xml file) below does:

```
<property name = "build.compiler"       value = "jikes"/>
<property name = "build.compiler.emacs" value = "true"/>
```

The 'errorformat' which handles ant with both javac and jikes is:

```
:set efm=\ %#[javac]\ %#%f:%l:%c:%*\\d:%*\\d:\ %t%[%^:]%#:%m,
         \%A\ %#[javac]\ %f:%l:\ %m,%-Z\ %#[javac]\ %p^,%-C%.%#
```

errorformat-jade

parsing jade (see http://www.jclark.com/) errors is simple:

```
:set efm=jade:%f:%l:%c:%t:%m
```

errorformat-LaTeX

The following is an example how an 'errorformat' string can be specified
for the (La)TeX typesetting system which displays error messages over
multiple lines. The output of ":clist" and ":cc" etc. commands displays
multi-lines in a single line, leading white space is removed.
It should be easy to adopt the above LaTeX errorformat to any compiler output
consisting of multi-line errors.

The commands can be placed in a vimrc file or some other Vim script file,
e.g. a script containing LaTeX related stuff which is loaded only when editing
LaTeX sources.
Make sure to copy all lines of the example (in the given order), afterwards
remove the comment lines. For the '\' notation at the start of some lines see
line-continuation.

First prepare 'makeprg' such that LaTeX will report multiple
errors; do not stop when the first error has occurred:

```
:set makeprg=latex\ \\\\nonstopmode\ \\\\input\\{$*}
```

Start of multi-line error messages:

```
:set efm=%E!\ LaTeX\ %trror:\ %m,
       \%E!\ %m,
```

Start of multi-line warning messages; the first two also
include the line number. Meaning of some regular expressions:

- "%.%#" (.*)   matches a (possibly empty) string

- "%*\\d" ("\d\+") matches a number

```
\%+WLaTeX\ %.%#Warning:\ %.%#line\ %l%.%#,
\%+W%.%#\ at\ lines\ %l--%*\\d,
\%WLaTeX\ %.%#Warning:\ %m,
```

Possible continuations of error/warning messages; the first
one also includes the line number:

```
\%Cl.%l\ %m,
\%+C\ \ %m.,
\%+C%.%#-%.%#,
\%+C%.%#[]%.%#,
\%+C[]%.%#,
\%+C%.%#%[{}\\]%.%#,
\%+C<%.%#>%.%#,
\%C\ \ %m,
```

Lines that match the following patterns do not contain any
important information; do not include them in messages:

```
\%-GSee\ the\ LaTeX%m,
\%-GType\ \ H\ <return>%m,
\%-G\ ...%.%#,
\%-G%.%#\ (C)\ %.%#,
\%-G(see\ the\ transcript%.%#),
```

Generally exclude any empty or whitespace-only line from
being displayed:

```
\%-G\\s%#,
```

The LaTeX output log does not specify the names of erroneous
source files per line; rather they are given globally,
enclosed in parentheses.
The following patterns try to match these names and store
them in an internal stack. The patterns possibly scan over
the same input line (one after another), the trailing "%r"
conversion indicates the "rest" of the line that will be
parsed in the next go until the end of line is reached.

Overread a file name enclosed in '('...')'; do not push it
on a stack since the file apparently does not contain any
error:

```
\%+O(%f)%r,
```

Push a file name onto the stack. The name is given after '(':

```
\%+P(%f%r,
\%+P\ %\\=(%f%r,
\%+P%*[^()](%f%r,
\%+P[%\\d%[^()]%#(%f%r,
```

Pop the last stored file name when a ')' is scanned:

```
\%+Q)%r,
\%+Q%*[^()])%r,
\%+Q[%\\d%*[^()])%r
```

Note that in some cases file names in the LaTeX output log cannot be parsed
properly. The parser might have been messed up by unbalanced parentheses
then. The above example tries to catch the most relevant cases only.
You can customize the given setting to suit your own purposes, for example,
all the annoying "Overfull ..." warnings could be excluded from being
recognized as an error.
Alternatively to filtering the LaTeX compiler output, it is also possible
to directly read the *.log file that is produced by the [La]TeX compiler.
This contains even more useful information about possible error causes.
However, to properly parse such a complex file, an external filter should
be used. See the description further above how to make such a filter known
by Vim.

10. Customizing the quickfix window quickfix-window-function

The default format for the lines displayed in the quickfix window and location
list window is:

```
<filename>|<lnum> col <col>|<text>
```

The values displayed in each line correspond to the "bufnr", "lnum", "col" and
"text" fields returned by the getqflist() function.

For some quickfix/location lists, the displayed text needs to be customized.
For example, if only the filename is present for a quickfix entry, then the
two "|" field separator characters after the filename are not needed. Another
use case is to customize the path displayed for a filename. By default, the
complete path (which may be too long) is displayed for files which are not
under the current directory tree. The file path may need to be simplified to
a common parent directory.

The displayed text can be customized by setting the 'quickfixtextfunc' option
to a Vim function. This function will be called with a dict argument and
should return a List of strings to be displayed in the quickfix or location
list window. The dict argument will have the following fields:

```
    quickfix    set to 1 when called for a quickfix list and 0 when called for
                a location list.
    winid       for a location list, set to the id of the window with the
                location list.  For a quickfix list, set to 0.  Can be used in
                getloclist() to get the location list entry.
    id          quickfix or location list identifier
    start_idx   index of the first entry for which text should be returned
    end_idx     index of the last entry for which text should be returned
```

The function should return a single line of text to display in the quickfix
window for each entry from start_idx to end_idx. The function can obtain
information about the entries using the getqflist() function and specifying
the quickfix list identifier "id". For a location list, getloclist() function
can be used with the "winid" argument. If an empty list is returned, then the
default format is used to display all the entries. If an item in the returned
list is an empty string, then the default format is used to display the
corresponding entry.

If a quickfix or location list specific customization is needed, then the
'quickfixtextfunc' attribute of the list can be set using the setqflist() or
setloclist() function. This overrides the global 'quickfixtextfunc' option.

The example below displays the list of old files (v:oldfiles) in a quickfix
window. As there is no line, column number and error text information
associated with each entry, the 'quickfixtextfunc' function returns only the
filename.
Example:

```
" create a quickfix list from v:oldfiles
call setqflist([], ' ', {'lines' : v:oldfiles, 'efm' : '%f',
                                    \ 'quickfixtextfunc' : 'QfOldFiles'})
func QfOldFiles(info)
    " get information about a range of quickfix entries
    let items = getqflist({'id' : a:info.id, 'items' : 1}).items
    let l = []
    for idx in range(a:info.start_idx - 1, a:info.end_idx - 1)
        " use the simplified file name
      call add(l, fnamemodify(bufname(items[idx].bufnr), ':p:.'))
    endfor
    return l
endfunc
```

Q_lr — Left-right motions

N is used to indicate an optional count that can be given before the command.

h	N	h	left (also: CTRL-H, <BS>, or <Left> key)
l	N	l	right (also: <Space> or <Right> key)
0		0	to first character in the line (also: <Home> key)
^		^	to first non-blank character in the line
$	N	$	to the next EOL (end of line) position (also: <End> key)
g0		g0	to first character in screen line (differs from "0" when lines wrap)
g^		g^	to first non-blank character in screen line (differs from "^" when lines wrap)
g$	N	g$	to last character in screen line (differs from "$" when lines wrap)
gm		gm	to middle of the screen line
gM		gM	to middle of the line
bar	N	|	to column N (default: 1)
f	N	f{char}	to the Nth occurrence of {char} to the right
F	N	F{char}	to the Nth occurrence of {char} to the left
t	N	t{char}	till before the Nth occurrence of {char} to the right
T	N	T{char}	till before the Nth occurrence of {char} to the left
;	N	;	repeat the last "f", "F", "t", or "T" N times
,	N	,	repeat the last "f", "F", "t", or "T" N times in opposite direction

Q_ud — Up-down motions

k	N	k	up N lines (also: CTRL-P and <Up>)
j	N	j	down N lines (also: CTRL-J, CTRL-N, <NL>, and <Down>)
-	N	-	up N lines, on the first non-blank character
+	N	+	down N lines, on the first non-blank character (also: CTRL-M and <CR>)
_	N	_	down N-1 lines, on the first non-blank character
G	N	G	goto line N (default: last line), on the first non-blank character
gg	N	gg	goto line N (default: first line), on the first non-blank character
N%	N	%	goto line N percentage down in the file; N must be given, otherwise it is the % command
gk	N	gk	up N screen lines (differs from "k" when line wraps)
gj	N	gj	down N screen lines (differs from "j" when line wraps)

Q_tm — Text object motions

w	N	w	N words forward
W	N	W	N blank-separated WORDs forward
e	N	e	forward to the end of the Nth word
E	N	E	forward to the end of the Nth blank-separated WORD
b	N	b	N words backward
B	N	B	N blank-separated WORDs backward
ge	N	ge	backward to the end of the Nth word
gE	N	gE	backward to the end of the Nth blank-separated WORD
)	N	)	N sentences forward
(	N	(	N sentences backward
}	N	}	N paragraphs forward
{	N	{	N paragraphs backward
]]	N	]]	N sections forward, at start of section
[[	N	[[	N sections backward, at start of section
][	N	][	N sections forward, at end of section
[]	N	[]	N sections backward, at end of section
[(	N	[(	N times back to unclosed '('

```
[{      N  [{           N times back to unclosed '{'
[m      N  [m           N times back to start of method (for Java)
[M      N  [M           N times back to end of method (for Java)
])      N  ])           N times forward to unclosed ')'
]}      N  ]}           N times forward to unclosed '}'
]m      N  ]m           N times forward to start of method (for Java)
]M      N  ]M           N times forward to end of method (for Java)
[#      N  [#           N times back to unclosed "#if" or "#else"
]#      N  ]#           N times forward to unclosed "#else" or "#endif"
[star   N  [*           N times back to start of comment "/*"
]star   N  ]*           N times forward to end of comment "*/"
```

Q_pa **Pattern searches**

```
/       N  /{pattern}[/[offset]]<CR>
                        search forward for the Nth occurrence of {pattern}
?       N  ?{pattern}[?[offset]]<CR>
                        search backward for the Nth occurrence of {pattern}
/<CR>   N  /<CR>        repeat last search, in the forward direction
?<CR>   N  ?<CR>        repeat last search, in the backward direction
n       N  n            repeat last search
N       N  N            repeat last search, in opposite direction
star    N  *            search forward for the identifier under the cursor
#       N  #            search backward for the identifier under the cursor
gstar   N  g*           like "*", but also find partial matches
g#      N  g#           like "#", but also find partial matches
gd         gd           goto local declaration of identifier under the cursor
gD         gD           goto global declaration of identifier under the cursor
```

pattern Special characters in search patterns

meaning	magic	nomagic
matches any single character	.	\.
matches start of line	^	^
matches <EOL>	$	$
matches start of word	\<	\<
matches end of word	\>	\>
matches a single char from the range	[a-z]	\[a-z]
matches a single char not in the range	[^a-z]	\[^a-z]
matches an identifier char	\i	\i
idem but excluding digits	\I	\I
matches a keyword character	\k	\k
idem but excluding digits	\K	\K
matches a file name character	\f	\f
idem but excluding digits	\F	\F
matches a printable character	\p	\p
idem but excluding digits	\P	\P
matches a white space character	\s	\s
matches a non-white space character	\S	\S

```
                              matches <Esc>    \e      \e
                              matches <Tab>    \t      \t
                               matches <CR>    \r      \r
                               matches <BS>    \b      \b

    matches 0 or more of the preceding atom    *       \*
    matches 1 or more of the preceding atom    \+      \+
       matches 0 or 1 of the preceding atom    \=      \=
       matches 2 to 5 of the preceding atom    \{2,5}  \{2,5}
                 separates two alternatives    \|      \|
              group a pattern into an atom     \(\)    \(\)
```

search-offset Offsets allowed after search command

```
    [num]       [num] lines downwards, in column 1
    +[num]      [num] lines downwards, in column 1
    -[num]      [num] lines upwards, in column 1
    e[+num]     [num] characters to the right of the end of the match
    e[-num]     [num] characters to the left of the end of the match
    s[+num]     [num] characters to the right of the start of the match
    s[-num]     [num] characters to the left of the start of the match
    b[+num]     [num] identical to s[+num] above (mnemonic: begin)
    b[-num]     [num] identical to s[-num] above (mnemonic: begin)
    ;{search-command}   execute {search-command} next
```

Q_ma **Marks and motions**

```
m       m{a-zA-Z}       mark current position with mark {a-zA-Z}
`a      `{a-z} go to mark {a-z} within current file
`A      `{A-Z} go to mark {A-Z} in any file
`0      `{0-9} go to the position where Vim was previously exited
``      ``              go to the position before the last jump
`quote  `"              go to the position when last editing this file
`[      `[              go to the start of the previously operated or put text
`]      `]              go to the end of the previously operated or put text
```

`<	`<		go to the start of the (previous) Visual area
`>	`>		go to the end of the (previous) Visual area
``	``		go to the position of the last change in this file
'	'{a-zA-Z0-9[]'"<>.}
			same as `, but on the first non-blank in the line
:marks	:marks	print the active marks
CTRL-O	N CTRL-O	go to Nth older position in jump list
CTRL-I	N CTRL-I	go to Nth newer position in jump list
:ju	:ju[mps]	print the jump list

Q_vm — Various motions

%	%		find the next brace, bracket, comment, or "#if"/
			"#else"/"#endif" in this line and go to its match
H	N H		go to the Nth line in the window, on the first
			non-blank
M	M		go to the middle line in the window, on the first
			non-blank
L	N L		go to the Nth line from the bottom, on the first
			non-blank

go	N go		go to Nth byte in the buffer
:go	:[range]go[to] [off]	go to [off] byte in the buffer

Q_ta — Using tags

:ta	:ta[g][!] {tag}	jump to tag {tag}
:ta	:[count]ta[g][!]	jump to [count]'th newer tag in tag list
CTRL-]	CTRL-]		jump to the tag under cursor, unless changes
			have been made
:ts	:ts[elect][!] [tag]	list matching tags and select one to jump to
:tjump	:tj[ump][!] [tag]	jump to tag [tag] or select from list when
			there are multiple matches
:ltag	:lt[ag][!] [tag]	jump to tag [tag] and add matching tags to the
			location list

:tags	:tags		print tag list
CTRL-T	N CTRL-T		jump back from Nth older tag in tag list
:po	:[count]po[p][!]	jump back from [count]'th older tag in tag list
:tnext	:[count]tn[ext][!]	jump to [count]'th next matching tag
:tp	:[count]tp[revious][!]	jump to [count]'th previous matching tag
:tr	:[count]tr[ewind][!]	jump to [count]'th matching tag
:tl	:tl[ast][!]		jump to last matching tag

:ptag	:pt[ag] {tag}	open a preview window to show tag {tag}
CTRL-W_}	CTRL-W }		like CTRL-] but show tag in preview window
:pts	:pts[elect]		like ":tselect" but show tag in preview window
:ptjump	:ptj[ump]		like ":tjump" but show tag in preview window
:pclose	:pc[lose]		close tag preview window
CTRL-W_z	CTRL-W z		close tag preview window

Q_sc — Scrolling

CTRL-E		N CTRL-E	window N lines downwards (default: 1)
CTRL-D		N CTRL-D	window N lines Downwards (default: 1/2 window)
CTRL-F		N CTRL-F	window N pages Forwards (downwards)
CTRL-Y		N CTRL-Y	window N lines upwards (default: 1)
CTRL-U		N CTRL-U	window N lines Upwards (default: 1/2 window)
CTRL-B		N CTRL-B	window N pages Backwards (upwards)
z<CR>		z<CR> or zt	redraw, current line at top of window
z.		z. or zz	redraw, current line at center of window
z-		z- or zb	redraw, current line at bottom of window

These only work when 'wrap' is off:
zh		N zh		scroll screen N characters to the right
zl		N zl		scroll screen N characters to the left
zH		N zH		scroll screen half a screenwidth to the right
zL		N zL		scroll screen half a screenwidth to the left

Q_in — Inserting text

a	N a	append text after the cursor (N times)
A	N A	append text at the end of the line (N times)
i	N i	insert text before the cursor (N times) (also: <Insert>)
I	N I	insert text before the first non-blank in the line (N times)
gI	N gI	insert text in column 1 (N times)
o	N o	open a new line below the current line, append text (N times)
O	N O	open a new line above the current line, append text (N times)
:startinsert	:star[tinsert][!]	start Insert mode, append when [!] used
:startreplace	:startr[eplace][!]	start Replace mode, at EOL when [!] used

in Visual block mode:
v_b_I	I	insert the same text in front of all the selected lines
v_b_A	A	append the same text after all the selected lines

Q_ai — Insert mode keys

insert-index	alphabetical index of Insert mode commands

leaving Insert mode:
i_<Esc>		<Esc>		end Insert mode, back to Normal mode
i_CTRL-C		CTRL-C		like <Esc>, but do not use an abbreviation
i_CTRL-O		CTRL-O {command}	execute {command} and return to Insert mode

moving around:

i_<Up>	cursor keys	move cursor left/right/up/down
i_<S-Left>	shift-left/right	one word left/right
i_<S-Up>	shift-up/down	one screenful backward/forward
i_<End>	<End>	cursor after last character in the line
i_<Home>	<Home>	cursor to first character in the line

Q_ss — Special keys in Insert mode

i_CTRL-V	CTRL-V {char}..	insert character literally, or enter decimal byte value
i_<NL>	<NL> or <CR> or CTRL-M or CTRL-J	begin new line
i_CTRL-E	CTRL-E	insert the character from below the cursor
i_CTRL-Y	CTRL-Y	insert the character from above the cursor
i_CTRL-A	CTRL-A	insert previously inserted text
i_CTRL-@	CTRL-@	insert previously inserted text and stop Insert mode
i_CTRL-R	CTRL-R {register}	insert the contents of a register
i_CTRL-N	CTRL-N	insert next match of identifier before the cursor
i_CTRL-P	CTRL-P	insert previous match of identifier before the cursor
i_CTRL-X	CTRL-X ...	complete the word before the cursor in various ways
i_<BS>	<BS> or CTRL-H	delete the character before the cursor
i_<Del>	<Del>	delete the character under the cursor
i_CTRL-W	CTRL-W	delete word before the cursor
i_CTRL-U	CTRL-U	delete all entered characters in the current line
i_CTRL-T	CTRL-T	insert one shiftwidth of indent in front of the current line
i_CTRL-D	CTRL-D	delete one shiftwidth of indent in front of the current line
i_0_CTRL-D	0 CTRL-D	delete all indent in the current line
i_^_CTRL-D	^ CTRL-D	delete all indent in the current line, restore indent in next line

Q_di — Digraphs

:dig	:dig[raphs]	show current list of digraphs
:dig	:dig[raphs] {char1}{char2} {number} ...	add digraph(s) to the list

In Insert or Command-line mode:

i_CTRL-K	CTRL-K {char1} {char2}	enter digraph
i_digraph	{char1} <BS> {char2}	enter digraph if 'digraph' option set

Q_si — Special inserts

:r	:r [file]	insert the contents of [file] below the cursor
:r!	:r! {command}	insert the standard output of {command} below the cursor

Q_de — Deleting text

x	N	x	delete N characters under and after the cursor
<Del>	N	<Del>	delete N characters under and after the cursor
X	N	X	delete N characters before the cursor
d	N	d{motion}	delete the text that is moved over with {motion}
v_d		{visual}d	delete the highlighted text
dd	N	dd	delete N lines
D	N	D	delete to the end of the line (and N-1 more lines)
J	N	J	join N-1 lines (delete <EOL>s)
v_J		{visual}J	join the highlighted lines
gJ	N	gJ	like "J", but without inserting spaces
v_gJ		{visual}gJ	like "{visual}J", but without inserting spaces
:d	:[range]d [x]		delete [range] lines [into register x]

Q_cm — Copying and moving text

quote	"{char}		use register {char} for the next delete, yank, or put
:reg	:reg		show the contents of all registers
:reg	:reg {arg}		show the contents of registers mentioned in {arg}
y	N	y{motion}	yank the text moved over with {motion} into a register
v_y		{visual}y	yank the highlighted text into a register
yy	N	yy	yank N lines into a register
Y	N	Y	yank N lines into a register **Note:** Mapped to "y$" by default. default-mappings
p	N	p	put a register after the cursor position (N times)
P	N	P	put a register before the cursor position (N times)
]p	N	]p	like p, but adjust indent to current line
[p	N	[p	like P, but adjust indent to current line
gp	N	gp	like p, but leave cursor after the new text
gP	N	gP	like P, but leave cursor after the new text

Q_ch — Changing text

```
r          N  r{char}    replace N characters with {char}
gr         N  gr{char}   replace N characters without affecting layout
R          N  R          enter Replace mode (repeat the entered text N times)
gR         N  gR         enter virtual Replace mode: Like Replace mode but
                            without affecting layout
v_b_r         {visual}r{char}
                         in Visual block mode: Replace each char of the
                            selected text with {char}

        (change = delete text and enter Insert mode)
c          N  c{motion}  change the text that is moved over with {motion}
v_c           {visual}c  change the highlighted text
cc         N  cc         change N lines
S          N  S          change N lines
C          N  C          change to the end of the line (and N-1 more lines)
s          N  s          change N characters
v_b_c         {visual}c  in Visual block mode: Change each of the selected
                            lines with the entered text
v_b_C         {visual}C  in Visual block mode: Change each of the selected
                            lines until end-of-line with the entered text

~          N  ~          switch case for N characters and advance cursor
v_~           {visual}~  switch case for highlighted text
v_u           {visual}u  make highlighted text lowercase
v_U           {visual}U  make highlighted text uppercase
g~            g~{motion} switch case for the text that is moved over with
                            {motion}
gu            gu{motion} make the text that is moved over with {motion}
                            lowercase
gU            gU{motion} make the text that is moved over with {motion}
                            uppercase
v_g?          {visual}g? perform rot13 encoding on highlighted text
g?            g?{motion} perform rot13 encoding on the text that is moved over
                            with {motion}

CTRL-A  N  CTRL-A       add N to the number at or after the cursor
CTRL-X  N  CTRL-X       subtract N from the number at or after the cursor

<          N  <{motion}  move the lines that are moved over with {motion} one
                            shiftwidth left
<<         N  <<         move N lines one shiftwidth left
>          N  >{motion}  move the lines that are moved over with {motion} one
                            shiftwidth right
>>         N  >>         move N lines one shiftwidth right
gq         N  gq{motion} format the lines that are moved over with {motion} to
                            'textwidth' length
:ce        :[range]ce[nter] [width]
                         center the lines in [range]
:le        :[range]le[ft] [indent]
                         left-align the lines in [range] (with [indent])
:ri        :[range]ri[ght] [width]
                         right-align the lines in [range]
```

Q_co — Complex changes

```
!          N  !{motion}{command}<CR>
                         filter the lines that are moved over through {command}
!!         N  !!{command}<CR>
                         filter N lines through {command}
v_!           {visual}!{command}<CR>
                         filter the highlighted lines through {command}
:range!   :[range]! {command}<CR>
                         filter [range] lines through {command}
=          N  ={motion}
                         filter the lines that are moved over through 'equalprg'
==         N  ==         filter N lines through 'equalprg'
v_=           {visual}=
                         filter the highlighted lines through 'equalprg'
:s         :[range]s[ubstitute]/{pattern}/{string}/[g][c]
                         substitute {pattern} by {string} in [range] lines;
                            with [g], replace all occurrences of {pattern};
                            with [c], confirm each replacement
:s         :[range]s[ubstitute] [g][c]
                         repeat previous ":s" with new range and options
&             &          Repeat previous ":s" on current line without options
:ret       :[range]ret[ab][!] [tabstop]
                         set 'tabstop' to new value and adjust white space
                            accordingly
```

Q_vi — Visual mode

```
visual-index    list of Visual mode commands.

v          v             start highlighting characters  }  move cursor and use
V          V             start highlighting linewise    }  operator to affect
CTRL-V     CTRL-V start highlighting blockwise   }  highlighted text
v_o        o             exchange cursor position with start of highlighting
gv         gv            start highlighting on previous visual area
v_v        v             highlight characters or stop highlighting
v_V        V             highlight linewise or stop highlighting
v_CTRL-V CTRL-V highlight blockwise or stop highlighting
```

Q_to — Text objects (only in Visual mode or after an operator)

```
v_aw        N  aw        Select "a word"
v_iw        N  iw        Select "inner word"
v_aW        N  aW        Select "a WORD"
v_iW        N  iW        Select "inner WORD"
v_as        N  as        Select "a sentence"
v_is        N  is        Select "inner sentence"

gs          N  gs        goto Sleep for N seconds
```

Q_km — Key mapping

```
:map        :ma[p] {lhs} {rhs}     map {lhs} to {rhs} in Normal and Visual mode
:map!       :ma[p]! {lhs} {rhs}  map {lhs} to {rhs} in Insert and Command-line
                                    mode
:noremap    :no[remap][!] {lhs} {rhs}
                                 same as ":map", no remapping for this {rhs}
:unmap      :unm[ap] {lhs}         remove the mapping of {lhs} for Normal and
                                    Visual mode
:unmap!     :unm[ap]! {lhs}        remove the mapping of {lhs} for Insert and
                                    Command-line mode
:map_l      :ma[p] [lhs]   list mappings (starting with [lhs]) for
                                    Normal and Visual mode
:map_l!     :ma[p]! [lhs]          list mappings (starting with [lhs]) for
                                    Insert and Command-line mode
:cmap       :cmap/:cunmap/:cnoremap
                                 like ":map!"/":unmap!"/":noremap!" but for
                                    Command-line mode only
:imap       :imap/:iunmap/:inoremap
                                 like ":map!"/":unmap!"/":noremap!" but for
                                    Insert mode only
:nmap       :nmap/:nunmap/:nnoremap
                                 like ":map"/":unmap"/":noremap" but for
                                    Normal mode only
:vmap       :vmap/:vunmap/:vnoremap
                                 like ":map"/":unmap"/":noremap" but for
                                    Visual mode only
:omap       :omap/:ounmap/:onoremap
                                 like ":map"/":unmap"/":noremap" but only for
                                    when an operator is pending
:mapc       :mapc[lear]    remove mappings for Normal and Visual mode
:mapc       :mapc[lear]!   remove mappings for Insert and Cmdline mode
:imapc      :imapc[lear]   remove mappings for Insert mode
:vmapc      :vmapc[lear]   remove mappings for Visual mode
:omapc      :omapc[lear]   remove mappings for Operator-pending mode
:nmapc      :nmapc[lear]   remove mappings for Normal mode
:cmapc      :cmapc[lear]   remove mappings for Cmdline mode
```

:mkexrc	:mk[exrc][!] [file]	write current mappings, abbreviations, and settings to [file] (default: ".exrc"; use ! to overwrite)
:mkvimrc	:mkv[imrc][!] [file]	same as :mkexrc, but with default ".nvimrc"
:mksession	:mks[ession][!] [file]	like ":mkvimrc", but store current files, windows, etc. too, to be able to continue this session later

Q_ab — Abbreviations

:abbreviate	:ab[breviate] {lhs} {rhs}	add abbreviation for {lhs} to {rhs}
:abbreviate	:ab[breviate] {lhs}	show abbr's that start with {lhs}
:abbreviate	:ab[breviate]	show all abbreviations
:unabbreviate	:una[bbreviate] {lhs}	remove abbreviation for {lhs}
:noreabbrev	:norea[bbrev] [lhs] [rhs]	like ":ab", but don't remap [rhs]
:iabbrev	:iab/:iunab/:inoreab	like ":ab", but only for Insert mode
:cabbrev	:cab/:cunab/:cnoreab	like ":ab", but only for Command-line mode
:abclear	:abc[lear]	remove all abbreviations
:cabclear	:cabc[lear]	remove all abbr's for Cmdline mode
:iabclear	:iabc[lear]	remove all abbr's for Insert mode

Q_op — Options

:set	:se[t]	show all modified options
:set	:se[t] all	show all options
:set	:se[t] {option}	set boolean option (switch it on), show string or number option
:set	:se[t] no{option}	reset boolean option (switch it off)
:set	:se[t] inv{option}	invert boolean option
:set	:se[t] {option}={value}	set string/number option to {value}
:set	:se[t] {option}+={value}	append {value} to string option, add {value} to number option
:set	:se[t] {option}-={value}	remove {value} to string option, subtract {value} from number option
:set	:se[t] {option}?	show value of {option}
:set	:se[t] {option}&	reset {option} to its default value
:setlocal	:setl[ocal]	like ":set" but set the local value for options that have one
:setglobal	:setg[lobal]	like ":set" but set the global value of a local option
:options	:opt[ions]	open a new window to view and set options, grouped by functionality, a one line explanation and links to the help

Short explanation of each option: option-list

'allowrevins'	'ari'	allow CTRL-_ in Insert mode
'ambiwidth'	'ambw'	what to do with Unicode chars of ambiguous width
'arabic'	'arab'	for Arabic as a default second language
'arabicshape'	'arshape'	do shaping for Arabic characters
'autochdir'	'acd'	change directory to the file in the current window
'autocomplete'	'ac'	enable automatic completion in insert mode
'autocompletedelay'	'acl'	delay in msec before menu appears after typing
'autocompletetimeout'	'act'	initial decay timeout for autocompletion algorithm
'autoindent'	'ai'	take indent for new line from previous line
'autoread'	'ar'	autom. read file when changed outside of Vim
'autowrite'	'aw'	automatically write file if changed
'autowriteall'	'awa'	as 'autowrite', but works with more commands
'background'	'bg'	"dark" or "light", used for highlight colors
'backspace'	'bs'	how backspace works at start of line
'backup'	'bk'	keep backup file after overwriting a file
'backupcopy'	'bkc'	make backup as a copy, don't rename the file
'backupdir'	'bdir'	list of directories for the backup file
'backupext'	'bex'	extension used for the backup file
'backupskip'	'bsk'	no backup for files that match these patterns
'belloff'	'bo'	do not ring the bell for these reasons
'binary'	'bin'	read/write/edit file in binary mode
'bomb'		prepend a Byte Order Mark to the file
'breakat'	'brk'	characters that may cause a line break
'breakindent'	'bri'	wrapped line repeats indent
'breakindentopt'	'briopt'	settings for 'breakindent'
'browsedir'	'bsdir'	which directory to start browsing in
'bufhidden'	'bh'	what to do when buffer is no longer in window
'buflisted'	'bl'	whether the buffer shows up in the buffer list
'buftype'	'bt'	special type of buffer
'casemap'	'cmp'	specifies how case of letters is changed
'cdhome'	'cdh'	change directory to the home directory by ":cd"
'cdpath'	'cd'	list of directories searched with ":cd"
'cedit'		key used to open the command-line window
'charconvert'	'ccv'	expression for character encoding conversion
'chistory'	'chi'	maximum number of quickfix lists in history
'cindent'	'cin'	do C program indenting
'cinkeys'	'cink'	keys that trigger indent when 'cindent' is set
'cinoptions'	'cino'	how to do indenting when 'cindent' is set
'cinscopedecls'	'cinsd'	words that are recognized by 'cino-g'
'cinwords'	'cinw'	words where 'si' and 'cin' add an indent

'clipboard'	'cb'	use the clipboard as the unnamed register
'cmdheight'	'ch'	number of lines to use for the command-line
'cmdwinheight'	'cwh'	height of the command-line window
'colorcolumn'	'cc'	columns to highlight
'columns'	'co'	number of columns in the display
'comments'	'com'	patterns that can start a comment line
'commentstring'	'cms'	template for comments; used for fold marker
'complete'	'cpt'	specify how Insert mode completion works
'completefunc'	'cfu'	function to be used for Insert mode completion
'completeopt'	'cot'	options for Insert mode completion
'completeslash'	'csl'	like 'shellslash' for completion
'completetimeout'	'cto'	initial decay timeout for CTRL-N and CTRL-P
'concealcursor'	'cocu'	whether concealable text is hidden in cursor line
'conceallevel'	'cole'	whether concealable text is shown or hidden
'confirm'	'cf'	ask what to do about unsaved/read-only files
'copyindent'	'ci'	make 'autoindent' use existing indent structure
'cpoptions'	'cpo'	flags for Vi-compatible behavior
'cursorbind'	'crb'	move cursor in window as it moves in other windows
'cursorcolumn'	'cuc'	highlight the screen column of the cursor
'cursorline'	'cul'	highlight the screen line of the cursor
'cursorlineopt'	'culopt'	settings for 'cursorline'
'debug'		set to "msg" to see all error messages
'define'	'def'	pattern to be used to find a macro definition
'delcombine'	'deco'	delete combining characters on their own
'dictionary'	'dict'	list of file names used for keyword completion
'diff'		use diff mode for the current window
'diffanchors'	'dia'	list of {address} to force anchoring of a diff
'diffexpr'	'dex'	expression used to obtain a diff file
'diffopt'	'dip'	options for using diff mode
'digraph'	'dg'	enable the entering of digraphs in Insert mode
'directory'	'dir'	list of directory names for the swap file
'display'	'dy'	list of flags for how to display text
'eadirection'	'ead'	in which direction 'equalalways' works
'encoding'	'enc'	encoding used internally
'endoffile'	'eof'	write CTRL-Z at end of the file
'endofline'	'eol'	write <EOL> for last line in file
'equalalways'	'ea'	windows are automatically made the same size
'equalprg'	'ep'	external program to use for "=" command
'errorbells'	'eb'	ring the bell for error messages
'errorfile'	'ef'	name of the errorfile for the QuickFix mode
'errorformat'	'efm'	description of the lines in the error file
'eventignore'	'ei'	autocommand events that are ignored
'eventignorewin'	'eiw'	autocommand events that are ignored in a window
'expandtab'	'et'	use spaces when <Tab> is inserted
'exrc'	'ex'	read init files in the current directory
'fileencoding'	'fenc'	file encoding for multibyte text
'fileencodings'	'fencs'	automatically detected character encodings
'fileformat'	'ff'	file format used for file I/O
'fileformats'	'ffs'	automatically detected values for 'fileformat'
'fileignorecase'	'fic'	ignore case when using file names
'filetype'	'ft'	type of file, used for autocommands
'fillchars'	'fcs'	characters to use for displaying special items
'findfunc'	'ffu'	function to be called for the :find command
'fixendofline'	'fixeol'	make sure last line in file has <EOL>
'foldclose'	'fcl'	close a fold when the cursor leaves it
'foldcolumn'	'fdc'	width of the column used to indicate folds
'foldenable'	'fen'	set to display all folds open
'foldexpr'	'fde'	expression used when 'foldmethod' is "expr"
'foldignore'	'fdi'	ignore lines when 'foldmethod' is "indent"
'foldlevel'	'fdl'	close folds with a level higher than this
'foldlevelstart'	'fdls'	'foldlevel' when starting to edit a file
'foldmarker'	'fmr'	markers used when 'foldmethod' is "marker"
'foldmethod'	'fdm'	folding type
'foldminlines'	'fml'	minimum number of lines for a fold to be closed
'foldnestmax'	'fdn'	maximum fold depth
'foldopen'	'fdo'	for which commands a fold will be opened
'foldtext'	'fdt'	expression used to display for a closed fold
'follow'		multicursor: motions cascade to all cursors
'formatexpr'	'fex'	expression used with "gq" command
'formatlistpat'	'flp'	pattern used to recognize a list header
'formatoptions'	'fo'	how automatic formatting is to be done
'formatprg'	'fp'	name of external program used with "gq" command
'fsync'	'fs'	whether to invoke fsync() after file write
'grepformat'	'gfm'	format of 'grepprg' output
'grepprg'	'gp'	program to use for ":grep"
'guicursor'	'gcr'	GUI: settings for cursor shape and blinking
'guifont'	'gfn'	GUI: Name(s) of font(s) to be used
'guifontwide'	'gfw'	list of font names for double-wide characters
'guioptions'	'go'	GUI: Which components and options are used
'guitablabel'	'gtl'	GUI: custom label for a tabpage
'guitabtooltip'	'gtt'	GUI: custom tooltip for a tabpage
'helpfile'	'hf'	full path name of the main help file
'helpheight'	'hh'	minimum height of a new help window
'helplang'	'hlg'	preferred help languages
'hidden'	'hid'	don't unload buffer when it is abandoned
'history'	'hi'	number of command-lines that are remembered
'hlsearch'	'hls'	highlight matches with last search pattern
'icon'		let Vim set the text of the window icon
'iconstring'		string to use for the Vim icon text
'ignorecase'	'ic'	ignore case in search patterns

'imcmdline'	'imc'	use IM when starting to edit a command line
'imdisable'	'imd'	do not use the IM in any mode
'iminsert'	'imi'	use :lmap or IM in Insert mode
'imsearch'	'ims'	use :lmap or IM when typing a search pattern
'include'	'inc'	pattern to be used to find an include file
'includeexpr'	'inex'	expression used to process an include line
'incsearch'	'is'	highlight match while typing search pattern
'indentexpr'	'inde'	expression used to obtain the indent of a line
'indentkeys'	'indk'	keys that trigger indenting with 'indentexpr'
'infercase'	'inf'	adjust case of match for keyword completion
'isfname'	'isf'	characters included in file names and pathnames
'isident'	'isi'	characters included in identifiers
'iskeyword'	'isk'	characters included in keywords
'joinspaces'	'js'	two spaces after a period with a join command
'jumpoptions'	'jop'	specifies how jumping is done
'keymap'	'kmp'	name of a keyboard mapping
'keymodel'	'km'	enable starting/stopping selection with keys
'keywordprg'	'kp'	program to use for the "K" command
'langmap'	'lmap'	alphabetic characters for other language mode
'langmenu'	'lm'	language to be used for the menus
'langremap'	'lrm'	do apply 'langmap' to mapped characters
'laststatus'	'ls'	tells when last window has status lines
'lazyredraw'	'lz'	don't redraw while executing macros
'lhistory'	'lhi'	maximum number of location lists in history
'linebreak'	'lbr'	wrap long lines at a blank
'lines'		number of lines in the display
'linespace'	'lsp'	number of pixel lines to use between characters
'lisp'		automatic indenting for Lisp
'lispoptions'	'lop'	changes how Lisp indenting is done
'lispwords'	'lw'	words that change how lisp indenting works
'list'		show <Tab> and <EOL>
'listchars'	'lcs'	characters for displaying in list mode
'loadplugins'	'lpl'	load plugin scripts when starting up
'makeef'	'mef'	name of the errorfile for ":make"
'makeencoding'	'menc'	encoding of external make/grep commands
'makeprg'	'mp'	program to use for the ":make" command
'matchpairs'	'mps'	pairs of characters that "%" can match
'matchtime'	'mat'	tenths of a second to show matching paren
'maxcombine'	'mco'	maximum nr of combining characters displayed
'maxfuncdepth'	'mfd'	maximum recursive depth for user functions
'maxmapdepth'	'mmd'	maximum recursive depth for mapping
'maxmempattern'	'mmp'	maximum memory (in Kbyte) used for pattern search
'menuitems'	'mis'	maximum number of items in a menu
'mkspellmem'	'msm'	memory used before :mkspell compresses the tree
'modeline'	'ml'	recognize modelines at start or end of file
'modelineexpr'	'mle'	allow setting expression options from a modeline
'modelines'	'mls'	number of lines checked for modelines
'modifiable'	'ma'	changes to the text are not possible
'modified'	'mod'	buffer has been modified
'more'		pause listings when the whole screen is filled
'mouse'		enable the use of mouse clicks
'mousefocus'	'mousef'	keyboard focus follows the mouse
'mousehide'	'mh'	hide mouse pointer while typing
'mousemodel'	'mousem'	changes meaning of mouse buttons
'mousemoveevent'	'mousemev'	report mouse moves with <MouseMove>
'mousescroll'		amount to scroll by when scrolling with a mouse
'mouseshape'	'mouses'	shape of the mouse pointer in different modes
'mousetime'	'mouset'	max time between mouse double-click
'nrformats'	'nf'	number formats recognized for CTRL-A command
'number'	'nu'	print the line number in front of each line
'numberwidth'	'nuw'	number of columns used for the line number
'omnifunc'	'ofu'	function for filetype-specific completion
'opendevice'	'odev'	allow reading/writing devices on MS-Windows
'operatorfunc'	'opfunc'	function to be called for g@ operator
'packpath'	'pp'	list of directories used for packages
'paragraphs'	'para'	nroff macros that separate paragraphs
'patchexpr'	'pex'	expression used to patch a file
'patchmode'	'pm'	keep the oldest version of a file
'path'	'pa'	list of directories searched with "gf" et.al.
'preserveindent'	'pi'	preserve the indent structure when reindenting
'previewheight'	'pvh'	height of the preview window
'previewwindow'	'pvw'	identifies the preview window
'pumheight'	'ph'	maximum number of items to show in the popup menu
'pumwidth'	'pw'	minimum width of the popup menu
'pyxversion'	'pyx'	Python version used for pyx* commands
'quoteescape'	'qe'	escape characters used in a string
'readonly'	'ro'	disallow writing the buffer
'redrawtime'	'rdt'	timeout for 'hlsearch' and :match highlighting
'regexpengine'	're'	default regexp engine to use
'relativenumber'	'rnu'	show relative line number in front of each line
'report'		threshold for reporting nr. of lines changed
'revins'	'ri'	inserting characters will work backwards
'rightleft'	'rl'	window is right-to-left oriented
'rightleftcmd'	'rlc'	commands for which editing works right-to-left
'ruler'	'ru'	show cursor line and column in the status line
'rulerformat'	'ruf'	custom format for the ruler
'runtimepath'	'rtp'	list of directories used for runtime files
'scroll'	'scr'	lines to scroll with CTRL-U and CTRL-D
'scrollbind'	'scb'	scroll in window as other windows scroll
'scrolljump'	'sj'	minimum number of lines to scroll

'scrolloff'	'so'	minimum nr. of lines above and below cursor
'scrolloffpad'	'sop'	vertically center cursor at end of file
'scrollopt'	'sbo'	how 'scrollbind' should behave
'sections'	'sect'	nroff macros that separate sections
'secure'		secure mode for reading .vimrc in current dir
'selection'	'sel'	what type of selection to use
'selectmode'	'slm'	when to use Select mode instead of Visual mode
'sessionoptions'	'ssop'	options for :mksession
'shada'	'sd'	use shada file upon startup and exiting
'shell'	'sh'	name of shell to use for external commands
'shellcmdflag'	'shcf'	flag to shell to execute one command
'shellpipe'	'sp'	string to put output of ":make" in error file
'shellquote'	'shq'	quote character(s) for around shell command
'shellredir'	'srr'	string to put output of filter in a temp file
'shellslash'	'ssl'	use forward slash for shell file names
'shelltemp'	'stmp'	whether to use a temp file for shell commands
'shellxescape'	'sxe'	characters to escape when 'shellxquote' is (
'shellxquote'	'sxq'	like 'shellquote', but include redirection
'shiftround'	'sr'	round indent to multiple of shiftwidth
'shiftwidth'	'sw'	number of spaces to use for (auto)indent step
'shortmess'	'shm'	list of flags, reduce length of messages
'showbreak'	'sbr'	string to use at the start of wrapped lines
'showcmd'	'sc'	show (partial) command somewhere
'showcmdloc'	'sloc'	where to show (partial) command
'showfulltag'	'sft'	show full tag pattern when completing tag
'showmatch'	'sm'	briefly jump to matching bracket if insert one
'showmode'	'smd'	message on status line to show current mode
'showtabline'	'stal'	tells when the tabpages line is displayed
'sidescroll'	'ss'	minimum number of columns to scroll horizontal
'sidescrolloff'	'siso'	min. nr. of columns to left and right of cursor
'signcolumn'	'scl'	when and how to display the sign column
'smartcase'	'scs'	no ignore case when pattern has uppercase
'smartindent'	'si'	smart autoindenting for C programs
'smarttab'	'sta'	<Tab> in leading whitespace indents by 'shiftwidth'
'smoothscroll'	'sms'	scroll by screen lines when 'wrap' is set
'softtabstop'	'sts'	number of columns between two soft tab stops
'spell'		enable spell checking
'spellcapcheck'	'spc'	pattern to locate end of a sentence
'spellfile'	'spf'	files where zg and zw store words
'spelllang'	'spl'	language(s) to do spell checking for
'spelloptions'	'spo'	options for spell checking
'spellsuggest'	'sps'	method(s) used to suggest spelling corrections
'splitbelow'	'sb'	new window from split is below the current one
'splitkeep'	'spk'	determines scroll behavior for split windows
'splitright'	'spr'	new window is put right of the current one
'startofline'	'sol'	commands move cursor to first non-blank in line
'statuscolumn'	'stc'	custom format for the status column
'statusline'	'stl'	custom format for the status line
'suffixes'	'su'	suffixes that are ignored with multiple match
'suffixesadd'	'sua'	suffixes added when searching for a file
'swapfile'	'swf'	whether to use a swapfile for a buffer
'switchbuf'	'swb'	sets behavior when switching to another buffer
'synmaxcol'	'smc'	maximum column to find syntax items
'syntax'	'syn'	syntax to be loaded for current buffer
'tabclose'	'tcl'	which tabpage to focus when closing a tab
'tabline'	'tal'	custom format for the console tabpages line
'tabpagemax'	'tpm'	maximum number of tabpages for -p and "tab all"
'tabstop'	'ts'	number of columns between two tab stops
'tagbsearch'	'tbs'	use binary searching in tags files
'tagcase'	'tc'	how to handle case when searching in tags files
'tagfunc'	'tfu'	function to get list of tag matches
'taglength'	'tl'	number of significant characters for a tag
'tagrelative'	'tr'	file names in tag file are relative
'tags'	'tag'	list of file names used by the tag command
'tagstack'	'tgst'	push tags onto the tag stack
'term'		name of the terminal
'termbidi'	'tbidi'	terminal takes care of bi-directionality
'termguicolors'	'tgc'	enable 24-bit RGB color in the TUI
'textwidth'	'tw'	maximum width of text that is being inserted
'thesaurus'	'tsr'	list of thesaurus files for keyword completion
'thesaurusfunc'	'tsrfu'	function to be used for thesaurus completion
'tildeop'	'top'	tilde command "~" behaves like an operator
'timeout'	'to'	time out on mappings and key codes
'timeoutlen'	'tm'	time out time in milliseconds
'title'		let Vim set the title of the window
'titlelen'		percentage of 'columns' used for window title
'titleold'		old title, restored when exiting
'titlestring'		string to use for the Vim window title
'ttimeout'		time out on mappings
'ttimeoutlen'	'ttm'	time out time for key codes in milliseconds
'ttytype'	'tty'	alias for 'term'
'undodir'	'udir'	where to store undo files
'undofile'	'udf'	save undo information in a file
'undolevels'	'ul'	maximum number of changes that can be undone
'undoreload'	'ur'	max nr of lines to save for undo on a buffer reload
'updatecount'	'uc'	after this many characters flush swap file
'updatetime'	'ut'	after this many milliseconds flush swap file
'varsofttabstop'	'vsts'	a list of number of columns between soft tab stops
'vartabstop'	'vts'	a list of number of columns between tab stops
'verbose'	'vbs'	give informative messages

'verbosefile'	'vfile'	file to write messages in
'viewdir'	'vdir'	directory where to store files with :mkview
'viewoptions'	'vop'	specifies what to save for :mkview
'virtualedit'	've'	when to use virtual editing
'visualbell'	'vb'	use visual bell instead of beeping
'warn'		warn for shell command when buffer was changed
'whichwrap'	'ww'	allow specified keys to cross line boundaries
'wildchar'	'wc'	command-line character for wildcard expansion
'wildcharm'	'wcm'	like 'wildchar' but also works when mapped
'wildignore'	'wig'	files matching these patterns are not completed
'wildignorecase'	'wic'	ignore case when completing file names
'wildmenu'	'wmnu'	use menu for command line completion
'wildmode'	'wim'	mode for 'wildchar' command-line expansion
'wildoptions'	'wop'	specifies how command line completion is done
'winaltkeys'	'wak'	when the windows system handles ALT keys
'window'	'wi'	nr of lines to scroll for CTRL-F and CTRL-B
'winfixbuf'	'wfb'	keep window focused on a single buffer
'winfixheight'	'wfh'	keep window height when opening/closing windows
'winfixwidth'	'wfw'	keep window width when opening/closing windows
'winheight'	'wh'	minimum number of lines for the current window
'winhighlight'	'winhl'	window-local highlighting
'winminheight'	'wmh'	minimum number of lines for any window
'winminwidth'	'wmw'	minimal number of columns for any window
'winwidth'	'wiw'	minimal number of columns for current window
'wrap'		long lines wrap and continue on the next line
'wrapmargin'	'wm'	chars from the right where wrapping starts
'wrapscan'	'ws'	searches wrap around the end of the file
'write'		writing to a file is allowed
'writeany'	'wa'	write to file with no need for "!" override
'writebackup'	'wb'	make a backup before overwriting a file
'writedelay'	'wd'	delay this many msec for each char (for debug)

Q_ur — Undo/Redo commands

u	N	u	undo last N changes
CTRL-R	N	CTRL-R	redo last N undone changes
U		U	restore last changed line

Q_et — External commands

:!	:!{command}	execute {command} with a shell
K	K	lookup keyword under the cursor with 'keywordprg' program (default: "man")

Q_qf — Quickfix commands

:cc	:cc [nr]	display error [nr] (default is the same again)
:cnext	:cn	display the next error
:cprevious	:cp	display the previous error
:clist	:cl	list all errors
:cfile	:cf	read errors from the file 'errorfile'
:cgetbuffer	:cgetb	like :cbuffer but don't jump to the first error
:cgetfile	:cg	like :cfile but don't jump to the first error
:cgetexpr	:cgete	like :cexpr but don't jump to the first error
:caddfile	:caddf	add errors from the error file to the current quickfix list
:caddexpr	:cad	add errors from an expression to the current quickfix list
:cbuffer	:cb	read errors from text in a buffer
:cexpr	:cex	read errors from an expression
:cquit	:cq	quit without writing and return error code (to the compiler)
:make	:make [args]	start make, read errors, and jump to first error
:grep	:gr[ep] [args]	execute 'grepprg' to find matches and jump to the first one

Q_vc — Various commands

CTRL-L	CTRL-L	clear and redraw the screen
CTRL-G	CTRL-G	show current file name (with path) and cursor position
ga	ga	show ascii value of character under cursor in decimal, hex, and octal
g8	g8	for utf-8 encoding: show byte sequence for character under cursor in hex
g_CTRL-G	g CTRL-G	show cursor column, line, and character position
CTRL-C	CTRL-C	during searches: Interrupt the search
<Del>	<Del>	while entering a count: delete last character
:version	:ve[rsion]	show version information
:normal	:norm[al][!] {commands}	execute Normal mode commands
:exmode	1q:	switch to Ex-mode

:redir	:redir >{file}	redirect messages to {file}
:silent	:silent[!] {command}	execute {command} silently
:confirm	:confirm {command}	quit, write, etc., asking about unsaved changes or read-only files
:browse	:browse {command}	open/read/write file, using a file selection dialog

Q_ce — Command-line editing

c_<Esc>	<Esc>	abandon command-line (if 'wildchar' is <Esc>, type it twice)
c_CTRL-V	CTRL-V {char}	insert {char} literally
c_CTRL-V	CTRL-V {number}	enter decimal value of character (up to three digits)
c_CTRL-K	CTRL-K {char1} {char2}	enter digraph (See Q_di)
c_CTRL-R	CTRL-R {register}	insert the contents of a register
c_<Left>	<Left>/<Right>	cursor left/right
c_<S-Left>	<S-Left>/<S-Right>	cursor one word left/right
c_CTRL-B	CTRL-B/CTRL-E	cursor to beginning/end of command-line
c_<BS>	<BS>	delete the character in front of the cursor
c_<Del>	<Del>	delete the character under the cursor
c_CTRL-W	CTRL-W	delete the word in front of the cursor
c_CTRL-U	CTRL-U	remove all characters between the cursor and beginning of command-line
c_<Up>	<Up>/<Down>	recall older/newer command-line that starts with current command
c_<S-Up>	<S-Up>/<S-Down>	recall older/newer command-line from history
c_CTRL-G	CTRL-G	next match when 'incsearch' is active
c_CTRL-T	CTRL-T	previous match when 'incsearch' is active
:history	:his[tory]	show older command-lines

Context-sensitive completion on the command-line:

c_wildchar	'wildchar' (default: <Tab>)	do completion on the pattern in front of the cursor; if there are multiple matches, beep and show the first one; further 'wildchar' will show the next ones
c_CTRL-D	CTRL-D	list all names that match the pattern in front of the cursor
c_CTRL-A	CTRL-A	insert all names that match pattern in front of cursor
c_CTRL-L	CTRL-L	insert longest common part of names that match pattern
c_CTRL-N	CTRL-N	after 'wildchar' with multiple matches: go to next match
c_CTRL-P	CTRL-P	after 'wildchar' with multiple matches: go to previous match

Q_ra — Ex ranges

:range	,	separates two line numbers
:range	;	idem, set cursor to the first line number before interpreting the second one
:range	{number}	an absolute line number
:range	.	the current line
:range	$	the last line in the file
:range	%	equal to 1,$ (the entire file)
:range	*	equal to '<,'> (visual area)
:range	't	position of mark t
:range	/{pattern}[/]	the next line where {pattern} matches
:range	?{pattern}[?]	the previous line where {pattern} matches
:range	+[num]	add [num] to the preceding line number (default: 1)
:range	-[num]	subtract [num] from the preceding line number (default: 1)

Q_ex — Special Ex characters

:bar	|	separates two commands (not for ":global" and ":!")
:quote	"	begins comment
:_%	%	current file name (only where a file name is expected)
:_#	#[num]	alternate file name [num] (only where a file name is expected)

Note: The next seven are typed literally; these are not special keys!

:<abuf>	<abuf>	buffer number, for use in an autocommand (only where a file name is expected)
:<afile>	<afile>	file name, for use in an autocommand (only where a file name is expected)
:<amatch>	<amatch>	what matched with the pattern, for use in an autocommand (only where a file name is expected)
:<cword>	<cword>	word under the cursor (only where a file name is expected)
:<cWORD>	<cWORD>	WORD under the cursor (only where a file name is expected) (see WORD)
:<cfile>	<cfile>	file name under the cursor (only where a file name is expected)
:<script>	<script>	file name of a ":source"d file, within that file (only where a file name is expected)

After "%", "#", "<cfile>", "<script>" or "<afile>"

::p	:p	full path
::h	:h	head (file name removed)
::t	:t	tail (file name only)
::r	:r	root (extension removed)

```
               ::e         :e          extension
               ::s         :s/{pat}/{repl}/    substitute {pat} with {repl}
```

Q_st — Starting Vim

```
-file      vim [options] {file} ..      start editing one or more files
--         vim [options] -              read file from stdin
-tag       vim [options] -t {tag}       edit the file associated with {tag}
-qf        vim [options] -q [fname]     start editing in QuickFix mode,
                                           display the first error

        Most useful Vim arguments (for full list see startup-options)

-+      +[num]              put the cursor at line [num] (default: last line)
-+c     +{command}          execute {command} after loading the file
-+/     +/{pat} {file} ..   put the cursor at the first occurrence of {pat}
-e      -e                  Ex-mode
-R      -R                  Read-only mode, implies -n
-m      -m                  modifications not allowed (resets 'write' option)
-d      -d                  diff-mode
-b      -b                  binary mode
-l      -l                  lisp mode
-A      -A                  Arabic mode ('arabic' is set)
-H      -H                  Hebrew mode (Hebrew keymap & 'rightleft' are set)
-V      -V                  Verbose, give informative messages
-r      -r                  give list of swap files
-r      -r {file} ..        recover aborted edit session
-n      -n                  do not create a swap file
-o      -o [num]            open [num] windows (default: one for each file)
-s      -s {scriptin}       first read commands from the file {scriptin}
-w      -w {scriptout}      write typed chars to file {scriptout} (append)
-W      -W {scriptout}      write typed chars to file {scriptout} (overwrite)
-u      -u {vimrc}          read inits from {vimrc} instead of other inits
-i      -i {shada}          read info from {shada} instead of other files
---     --                  end of options, other arguments are file names
--help    --help            show list of arguments and exit
--version --version         show version info and exit
--       -                  read file from stdin
```

Q_ed — Editing a file

```
           Without !: Fail if changes have been made to the current buffer.
              With !: Discard any changes to the current buffer.
:edit_f  :e[dit][!] {file}      edit {file}
:edit    :e[dit][!]             reload the current file
:enew    :ene[w][!]             edit a new, unnamed buffer
:find    :fin[d][!] {file}      find {file} in 'path' and edit it

CTRL-^   N  CTRL-^              edit alternate file N (equivalent to ":e #N")
gf          gf  or ]f           edit the file whose name is under the cursor
:pwd     :pwd                   print the current directory name
:cd      :cd [path]             change the current directory to [path]
:cd-     :cd -          back to previous current directory
:file    :f[ile]                print the current file name and the cursor
                                   position
:file    :f[ile] {name} set the current file name to {name}
:files   :files         show alternate file names
```

Q_fl — Using the argument list — argument-list

```
:args      :ar[gs]              print the argument list, with the current file
                                   in "[]"
:all       :all  or :sall       open a window for every file in the arg list
:wn        :wn[ext][!]          write file and edit next file
:wn        :wn[ext][!] {file}   write to {file} and edit next file, unless
                                   {file} exists; With !, overwrite existing
                                   file
:wN        :wN[ext][!] [file]   write file and edit previous file
```

in current window	in new window	action
:argument :argu[ment] N	:sar[gument] N	edit file N
:next :n[ext]	:sn[ext]	edit next file
:next_f :n[ext] {arglist}	:sn[ext] {arglist}	define new arg list and edit first file
:Next :N[ext]	:sN[ext]	edit previous file
:first :fir[st]	:sfir[st]	edit first file
:last :la[st]	:sla[st]	edit last file

Q_wq — Writing and quitting

```
:w         :[range]w[rite][!]            write to the current file
:w_f       :[range]w[rite] {file}        write to {file}, unless it already
                                           exists
:w_f       :[range]w[rite]! {file}       write to {file}.  Overwrite an existing
                                           file
:w_a       :[range]w[rite][!] >>         append to the current file
:w_a       :[range]w[rite][!] >> {file}  append to {file}
:w_c       :[range]w[rite] !{cmd}        execute {cmd} with [range] lines as
                                           standard input
```

```
:up       :[range]up[date][!]          write to current file if modified
:wall     :wa[ll][!]                   write all changed buffers

:q        :q[uit]              quit current buffer, unless changes have been
                                  made; Exit Vim when there are no other
                                  non-help buffers
:q        :q[uit]!             quit current buffer always, discard any
                                  changes.  Exit Vim when there are no other
                                  non-help buffers
:qa       :qa[ll]              exit Vim, unless changes have been made
:qa       :qa[ll]!             exit Vim always, discard any changes
:cq       :cq                  quit without writing and return error code

:wq       :wq[!]               write the current file and exit
:wq       :wq[!] {file}        write to {file} and exit
:xit      :x[it][!] [file]     like ":wq" but write only when changes have
                                  been made
ZZ           ZZ                same as ":x"
ZQ           ZQ                same as ":q!"
:xall     :xa[ll][!]  or :wqall[!]
                               write all changed buffers and exit

:stop     :st[op][!]           suspend Vim or start new shell; if 'aw' option
                                  is set and [!] not given write the buffer
CTRL-Z     CTRL-Z              same as ":stop"
```

Q_ac — Automatic Commands

```
shada-file      read registers, marks, history at startup, save when exiting.

:rshada         :rsh[ada] [file]        read info from ShaDa file [file]
:rshada         :rsh[ada]! [file]       idem, overwrite existing info
:wshada         :wsh[ada] [file]        add info to ShaDa file [file]
:wshada         :wsh[ada]! [file]       write info to ShaDa file [file]

modeline        Automatic option setting when editing a file

modeline        vim:{set-arg}: ..       In the first and last lines of the
                                        file (see 'ml' option), {set-arg} is
                                        given as an argument to ":set"

autocommand     Automatic execution of commands on certain events.

:autocmd        :au                       list all autocommands
:autocmd        :au {event}               list all autocommands for {event}
:autocmd        :au {event} {pat}         list all autocommands for {event}
                                          with {pat}
:autocmd        :au {event} {pat} {cmd}   enter new autocommands for {event}
                                          with {pat}
:autocmd        :au!                      remove all autocommands
:autocmd        :au! {event}              remove all autocommands for {event}
:autocmd        :au! * {pat}              remove all autocommands for {pat}
:autocmd        :au! {event} {pat}        remove all autocommands for {event}
                                          with {pat}
:autocmd        :au! {event} {pat} {cmd}  remove all autocommands for {event}
                                          with {pat} and enter new one
```

Q_wi — Multi-window commands

```
CTRL-W_s        CTRL-W s  or  :split    split window into two parts
:split_f        :split {file}           split window and edit {file} in one of
                                           them
:vsplit         :vsplit {file}          same, but split vertically
:vertical       :vertical {cmd}         make {cmd} split vertically

:sfind          :sf[ind] {file}         split window, find {file} in 'path'
                                           and edit it
:terminal       :terminal {cmd}         open a terminal window
CTRL-W_l        CTRL-W ]                split window and jump to tag under
                                           cursor
CTRL-W_f        CTRL-W f                split window and edit file name under
                                           the cursor
CTRL-W_^        CTRL-W ^                split window and edit alternate file
CTRL-W_n        CTRL-W n  or  :new      create new empty window
CTRL-W_q        CTRL-W q  or  :q[uit]   quit editing and close window
CTRL-W_c        CTRL-W c  or  :clo[se]  make buffer hidden and close window
CTRL-W_o        CTRL-W o  or  :on[ly]   make current window only one on the
                                           screen

CTRL-W_j        CTRL-W j                move cursor to window below
CTRL-W_k        CTRL-W k                move cursor to window above
CTRL-W_CTRL-W   CTRL-W CTRL-W           move cursor to window below (wrap)
CTRL-W_W        CTRL-W W                move cursor to window above (wrap)
CTRL-W_t        CTRL-W t                move cursor to top window
CTRL-W_b        CTRL-W b                move cursor to bottom window
CTRL-W_p        CTRL-W p                move cursor to previous active window

CTRL-W_r        CTRL-W r                rotate windows downwards
CTRL-W_R        CTRL-W R                rotate windows upwards
CTRL-W_x        CTRL-W x                exchange current window with next one

CTRL-W_=        CTRL-W =                make all windows equal height & width
CTRL-W_-        CTRL-W -                decrease current window height
CTRL-W_+        CTRL-W +                increase current window height
CTRL-W__        CTRL-W _                set current window height (default:
                                           very high)
```

CTRL-W_<	CTRL-W <	decrease current window width
CTRL-W_>	CTRL-W >	increase current window width
CTRL-W_bar	CTRL-W |	set current window width (default:
		widest possible)

Q_bu Buffer list commands

:buffers	:buffers or :files	list all known buffer and file names

:ball	:ball or :sball	edit all args/buffers
:unhide	:unhide or :sunhide	edit all loaded buffers

:badd	:badd {fname}	add file name {fname} to the list
:bunload	:bunload[!] [N]	unload buffer [N] from memory
:bdelete	:bdelete[!] [N]	unload buffer [N] and delete it from
		the buffer list

	in current window	**in new window**	
:buffer	:[N]buffer [N]	:[N]sbuffer [N]	to arg/buf N
:bnext	:[N]bnext [N]	:[N]sbnext [N]	to Nth next arg/buf
:bNext	:[N]bNext [N]	:[N]sbNext [N]	to Nth previous arg/buf
:bprevious	:[N]bprevious [N]	:[N]sbprevious [N]	to Nth previous arg/buf
:bfirst	:bfirst	:sbfirst	to first arg/buf
:blast	:blast	:sblast	to last arg/buf
:bmodified	:[N]bmod [N]	:[N]sbmod [N]	to Nth modified buf

Q_sy Syntax Highlighting

:syn-on	:syntax on	start using syntax highlighting
:syn-off	:syntax off	stop using syntax highlighting

:syn-keyword	:syntax keyword {group-name} {keyword} ..
		add a syntax keyword item
:syn-match	:syntax match {group-name} {pattern} ...
		add syntax match item
:syn-region	:syntax region {group-name} {pattern} ...
		add syntax region item
:syn-sync	:syntax sync [ccomment | lines {N} | ...]
		tell syntax how to sync
:syntax	:syntax [list]	list current syntax items
:syn-clear	:syntax clear	clear all syntax info

:highlight	:highlight clear	clear all highlight info
:highlight	:highlight {group-name} {key}={arg} ..
		set highlighting for {group-name}

:filetype	:filetype on	switch on file type detection, without
		syntax highlighting
:filetype	:filetype plugin indent on
		switch on file type detection, with
		automatic indenting and settings

Q_gu GUI commands

:menu	:menu	list all menus
:menu	:menu {mpath}	list menus starting with {mpath}
:menu	:menu {mpath} {rhs}	add menu {mpath}, giving {rhs}
:menu	:menu {pri} {mpath} {rhs}
		idem, with priorities {pri}
:menu	:menu ToolBar.{name} {rhs}
		add toolbar item, giving {rhs}
:tmenu	:tmenu {mpath} {text}	add tooltip to menu {mpath}
:unmenu	:unmenu {mpath}	remove menu {mpath}

Q_fo Folding

'foldmethod'	set foldmethod=manual	manual folding
	set foldmethod=indent	folding by indent
	set foldmethod=expr	folding by 'foldexpr'
	set foldmethod=syntax	folding by syntax regions
	set foldmethod=marker	folding by 'foldmarker'

zf	zf{motion}	operator: Define a fold manually
:fold	:{range}fold	define a fold for {range} lines
zd	zd	delete one fold under the cursor
zD	zD	delete all folds under the cursor

zo	zo	open one fold under the cursor
zO	zO	open all folds under the cursor
zc	zc	close one fold under the cursor
zC	zC	close all folds under the cursor

zm	zm	fold more: decrease 'foldlevel'
zM	zM	close all folds: make 'foldlevel' zero
zr	zr	reduce folding: increase 'foldlevel'
zR	zR	open all folds: make 'foldlevel' max.

zn	zn	fold none: reset 'foldenable'
zN	zN	fold normal set 'foldenable'
zi	zi	invert 'foldenable'

Recovery after a crash

You have spent several hours typing in that text that has to be finished
next morning, and then disaster strikes: Your computer crashes.

DON'T PANIC!

You can recover most of your changes from the files that Vim uses to store
the contents of the file. Mostly you can recover your work with one command:
vim -r filename

1. The swap file swap-file

Vim stores the things you changed in a swap file. Using the original file
you started from plus the swap file you can mostly recover your work.

You can see the name of the current swap file being used with the command:

:sw[apname] :sw :swapname

Or you can use the swapname() function, which also allows for seeing the
swap file name of other buffers.

The name of the swap file is normally the same as the file you are editing,
with the extension ".swp".

- On Unix, a '.' is prepended to swap file names in the same directory as the edited file. This avoids that the swap file shows up in a directory listing.
- If this file already exists (e.g., when you are recovering from a crash) a warning is given and another extension is used, ".swo", ".swn", etc.
- An existing file will never be overwritten.
- The swap file is deleted as soon as Vim stops editing the file.

E326

Technical: If the ".swp" file name already exists, the last character is
decremented until there is no file with that name or ".saa" is
reached. In the last case, no swap file is created.

By setting the 'directory' option you can place the swap file in another place
than where the edited file is.
Advantages:

- You will not pollute the directories with ".swp" files.
- When the 'directory' is on another partition, reduce the risk of damaging the file system where the file is (in a crash).

Disadvantages:

- You can get name collisions from files with the same name but in different directories (although Vim tries to avoid that by comparing the path name). This will result in bogus ATTENTION warning messages.
- When you use your home directory, and somebody else tries to edit the same file, that user will not see your swap file and will not get the ATTENTION warning message.

If you want to put swap files in a fixed place, put a command resembling the
following ones in your vimrc:

```
:set dir=~/tmp          (for Unix)
:set dir=c:\\tmp        (for Win32)
```

This is also very handy when editing files on floppy. Of course you will have
to create that "tmp" directory for this to work!

For read-only files, a swap file is not used right away. The swap file is
created only when making changes.

The 'swapfile' option can be reset to avoid creating a swapfile. And the
:noswapfile modifier can be used to not create a swapfile for a new buffer.

:nos[wapfile] {command} :nos :noswapfile
Execute {command}. If it contains a command that loads a new
buffer, it will be loaded without creating a swapfile and the
'swapfile' option will be reset. If a buffer already had a
swapfile it is not removed and 'swapfile' is not reset.

Detecting an existing swap file

You can find this in the user manual, section 11.3.

W325

The default SwapExists handler (default-autocmds) skips the E325 prompt
(and automatically chooses "(E)dit") if the swapfile owner process is still
running and owned by the current user. This presumes that you normally don't
want to be bothered with the ATTENTION message just because you happen to

edit the same file from multiple Nvim instances. In the worst case (a system crash) there will be more than one swapfile for the file; use :recover to inspect all of its swapfiles.

Updating the swapfile

The swap file is updated after typing 200 characters or when you have not typed anything for four seconds. This only happens if the buffer was changed, not when you only moved around. The reason why it is not kept up to date all the time is that this would slow down normal work too much. You can change the 200 character count with the 'updatecount' option. You can set the time with the 'updatetime' option. The time is given in milliseconds. After writing to the swap file Vim syncs the file to disk.

If the writing to the swap file is not wanted, it can be switched off by setting the 'updatecount' option to 0. The same is done when starting Vim with the "-n" option. Writing can be switched back on by setting the 'updatecount' option to non-zero. Swap files will be created for all buffers when doing this. But when setting 'updatecount' to zero, the existing swap files will not be removed, it will only affect files that will be opened after this.

If you want to make sure that your changes are in the swap file use this command:

:pre :preserve E313 E314

:pre[serve] Write all text for the current buffer into its swap file. The original file is no longer needed for recovery.

A Vim swap file can be recognized by the first six characters: "b0VIM ". After that comes the version number, e.g., "3.0".

Links and symbolic links

On Unix it is possible to have two names for the same file. This can be done with hard links and with symbolic links (symlinks).

For hard links Vim does not know the other name of the file. Therefore, the name of the swapfile will be based on the name you used to edit the file. There is no check for editing the same file by the other name too, because Vim cannot find the other swapfile (except for searching all of your harddisk, which would be very slow).

For symbolic links Vim resolves the links to find the name of the actual file. The swap file name is based on that name. Thus it doesn't matter by what name you edit the file, the swap file name will normally be the same. However, there are exceptions:

- When the directory of the actual file is not writable the swapfile is put elsewhere.
- When the symbolic links somehow create a loop you get an E773 error message and the unmodified file name will be used. You won't be able to save your file normally.

2. Recovery recovery E308 E311

Basic file recovery is explained in the user manual: usr_11.txt.

Another way to do recovery is to start Vim and use the ":recover" command. This is easy when you start Vim to edit a file and you get the "ATTENTION: Found a swap file ..." message. In this case the single command ":recover" will do the work. You can also give the name of the file or the swap file to the recover command:

:rec :recover E305 E306 E307

:rec[over] [file] Try to recover [file] from the swap file. If [file] is not given use the file name for the current buffer. The current contents of the buffer are lost. This command fails if the buffer was modified.

:rec[over]! [file] Like ":recover", but any changes in the current buffer are lost.

E312 E309 E310 E1364

Vim has some intelligence about what to do if the swap file is corrupt in some way. If Vim has doubt about what it found, it will give an error message and insert lines with "???" in the text. If you see an error message while recovering, search in the file for "???" to see what is wrong. You may want to cut and paste to get the text you need.

The most common remark is "???LINES MISSING". This means that Vim cannot read the text from the original file. This can happen if the system crashed and parts of the original file were not written to disk.

Be sure that the recovery was successful before overwriting the original file or deleting the swap file. It is good practice to write the recovered file elsewhere and run 'diff' to find out if the changes you want are in the recovered file. Or use :DiffOrig.

Once you are sure the recovery is ok delete the swap file. Otherwise, you will continue to get warning messages that the ".swp" file already exists.

Note: Recovering swap files is best-effort. Vim attempts to validate fields and skip corrupted sections, but the swap file format is intended for files you trust. A crafted swap file may trigger parser bugs; such reports are treated as robustness issues rather than security vulnerabilities.

Vim client-server communication

1. Common functionality clientserver

Nvim's RPC functionality allows clients to programmatically control Nvim. Nvim itself takes command-line arguments that cause it to become a client to another Nvim running as a server. These arguments match those provided by Vim's clientserver option.

The following command line arguments are available:

--remote [+{cmd}] {file} ... --remote

Open the file list in a remote Vim. When there is no Vim server, execute locally. Vim allows one init command: +{cmd}. This must be an Ex command that can be followed by "|". It's not yet supported by Nvim. The rest of the command line is taken as the file list. Thus any non-file arguments must come before this. You cannot edit stdin this way --. The remote Vim is raised. If you don't want this use

```
nvim --remote-send "<C-\><C-N>:n filename<CR>"
```

--remote-silent [+{cmd}] {file} ... --remote-silent

As above, but don't complain if there is no server and the file is edited locally.

--remote-tab --remote-tab

Like --remote but open each file in a new tabpage.

--remote-tab-silent --remote-tab-silent

Like --remote-silent but open each file in a new tabpage.

--remote-send {keys} --remote-send

Send {keys} to server and exit. The {keys} are not mapped. Special key names are recognized, e.g., "<CR>" results in a CR character.

--remote-expr {expr} --remote-expr

Evaluate {expr} in server and print the result on stdout.

--remote-ui --remote-ui

Display the UI of the server in the terminal. Fully interactive: keyboard and mouse input are forwarded to the server.

--server {addr} --server

Connect to the named pipe or socket at the given address for executing remote commands. See --listen for specifying an address when starting a server.

Examples

Start an Nvim server listening on a named pipe at '~/.cache/nvim/server.pipe':

```
nvim --listen ~/.cache/nvim/server.pipe
```

Edit "file.txt" in an Nvim server listening at '~/.cache/nvim/server.pipe':

```
nvim --server ~/.cache/nvim/server.pipe --remote file.txt
```

This doesn't work, all arguments after --remote will be used as file names:

```
nvim --remote --server ~/.cache/nvim/server.pipe file.txt
```

Tell the remote server to write all files and exit:

```
nvim --server ~/.cache/nvim/server.pipe --remote-send '<C-\><C-N>:wqa<CR>'
```

REMOTE EDITING

The --remote argument will cause a :drop command to be constructed from the rest of the command line and sent as described above.
Note that the --remote and --remote-wait arguments will consume the rest of

the command line. I.e. all remaining arguments will be regarded as filenames.
You can not put options there!

2. Missing functionality

E5600 clientserver-missing

Vim supports additional functionality in clientserver that's not yet
implemented in Nvim. In particular, none of the "wait" variants are supported
yet. The following command line arguments are not yet available:

--remote-wait [+{cmd}] {file} ... --remote-wait

Not yet supported by Nvim.
As --remote, but wait for files to complete
(unload) in remote Vim.

--remote-wait-silent [+{cmd}] {file} ... --remote-wait-silent

Not yet supported by Nvim.
As --remote-wait, but don't complain if there
is no server.

--remote-tab-wait --remote-tab-wait

Not yet supported by Nvim.
Like --remote-wait but open each file in a new
tabpage.

--remote-tab-wait-silent --remote-tab-wait-silent

Not yet supported by Nvim.
Like --remote-wait-silent but open each file
in a new tabpage.

Nvim support for remote plugins

1. Introduction

remote-plugin-intro

Extensibility is a primary goal of Nvim. Any programming language may be used to extend Nvim without changes to Nvim itself. This is achieved with remote plugins, coprocesses that have a direct communication channel (via RPC) with the Nvim process.

Even though these plugins run in separate processes they can call, be called, and receive events just as if the plugin's code were executed in the main process.

2. Plugin hosts

remote-plugin-hosts

While plugins can be implemented as arbitrary programs that communicate directly with the high-level Nvim API and are called via rpcrequest() and rpcnotify(), that is not the best approach. Instead, developers should first check whether a plugin host is available for their chosen programming language.

Plugin hosts are programs that provide a high-level environment for plugins, taking care of most boilerplate involved in defining commands, autocmds, and functions implemented over RPC connections. Hosts are loaded only when one of their registered plugins require it, keeping Nvim's startup as fast as possible, even if many plugins/hosts are installed.

3. Example

remote-plugin-example

The best way to learn about remote plugins is with an example, so let's see what a Python plugin looks like. This plugin exports a command, a function, and an autocmd. The plugin is called 'Limit', and all it does is limit the number of requests made to it. Here's the plugin source code:

```
import pynvim

@pynvim.plugin
class Limit(object):
    def __init__(self, vim):
        self.vim = vim
        self.calls = 0

    @pynvim.command('Cmd', range='', nargs='*', sync=True)
    def command_handler(self, args, range):
        self._increment_calls()
        self.vim.current.line = (
            'Command: Called %d times, args: %s, range: %s' % (self.calls,
                                                               args,
                                                               range))

    @pynvim.autocmd('BufEnter', pattern='*.py', eval='expand("<afile>")',
                    sync=True)
    def autocmd_handler(self, filename):
        self._increment_calls()
        self.vim.current.line = (
            'Autocmd: Called %s times, file: %s' % (self.calls, filename))

    @pynvim.function('Func')
    def function_handler(self, args):
        self._increment_calls()
        self.vim.current.line = (
            'Function: Called %d times, args: %s' % (self.calls, args))

    def _increment_calls(self):
        if self.calls == 5:
            raise Exception('Too many calls!')
        self.calls += 1
```

As can be seen, the plugin is implemented using idiomatic Python (classes, methods, and decorators). The translation between these language-specific idioms to Vimscript occurs while the plugin manifest is being generated (see the next section).

Notice that the exported command and autocmd are defined with the "sync" flag, which affects how Nvim calls the plugin: with "sync" the rpcrequest() function is used, which will block Nvim until the handler function returns a value. Without the "sync" flag, the call is made using a fire and forget approach with rpcnotify(), meaning return values or exceptions raised in the handler function are ignored.

To test the above plugin, it must be saved in "rplugin/python" in a 'runtimepath' directory (~/.config/nvim/rplugin/python/limit.py for example). Then, the remote plugin manifest must be generated with :UpdateRemotePlugins.

4. Remote plugin manifest

remote-plugin-manifest

:UpdateRemotePlugins

Just installing remote plugins to "rplugin/{host}" isn't enough for them to be automatically loaded when required. You must execute :UpdateRemotePlugins

every time a remote plugin is installed, updated, or deleted.

:UpdateRemotePlugins generates the remote plugin manifest, a special Vimscript file containing declarations for all Vimscript entities (commands/autocommands/functions) defined by all remote plugins, with each entity associated with the host and plugin path.

Manifest declarations are just calls to the remote#host#RegisterPlugin function, which takes care of bootstrapping the host as soon as the declared command, autocommand, or function is used for the first time.

The manifest generation step is necessary to keep Nvim's startup fast in situations where a user has remote plugins with different hosts. For example, say a user has three plugins, for Python, Java and .NET hosts respectively. If we were to load all three plugins at startup, then three language runtimes would also be spawned, which could take seconds!

With the manifest, each host will only be loaded when required. Continuing with the example, say the Java plugin is a semantic completion engine for Java code. If it defines the autocommand BufEnter *.java, then the Java host is spawned only when Nvim loads a buffer matching "*.java".

If the explicit call to :UpdateRemotePlugins seems inconvenient, try to see it like this: It's a way to provide IDE capabilities in Nvim while still keeping it fast and lightweight for general use. It's also analogous to the :helptags command.

$NVIM_RPLUGIN_MANIFEST

Unless $NVIM_RPLUGIN_MANIFEST is set the manifest will be written to a file named rplugin.vim at:

Unix
: $XDG_DATA_HOME/nvim/ or ~/.local/share/nvim/

Windows
: $LOCALAPPDATA/nvim/ or ~/AppData/Local/nvim/

Scrolling

These commands move the contents of the window. If the cursor position is moved off of the window, the cursor is moved onto the window (with 'scrolloff' screen lines around it). A page is the number of lines in the window minus two. The mnemonics for these commands may be a bit confusing. Remember that the commands refer to moving the window (the part of the buffer that you see) upwards or downwards in the buffer. When the window moves upwards in the buffer, the text in the window moves downwards on your screen.

See section 03.7 of the user manual for an introduction.

1. Scrolling downwards

scroll-down

The following commands move the edit window (the part of the buffer that you see) downwards (this means that more lines downwards in the text buffer can be seen):

CTRL-E

CTRL-E Scroll window [count] lines downwards in the buffer. The text moves upwards on the screen. Mnemonic: Extra lines.

CTRL-D

CTRL-D Scroll window Downwards in the buffer. The number of lines comes from the 'scroll' option (default: half a screen). If [count] given, first set 'scroll' option to [count]. The cursor is moved the same number of lines down in the file (if possible; when lines wrap and when hitting the end of the file there may be a difference). When the cursor is on the last line of the buffer nothing happens and a beep is produced. See also 'startofline' option.

<S-Down> or <S-Down> <kPageDown>
<PageDown> or <PageDown> CTRL-F
<S-CR> or <S-CR> <S-NL>
<S-+> or SHIFT-+ <S-Plus>

CTRL-F Scroll window [count] pages Forwards (downwards) in the buffer. See also 'startofline' option. When there is only one window the 'window' option might be used.

z+

z+ Without [count]: Redraw with the line just below the window at the top of the window. Put the cursor in that line, at the first non-blank in the line. With [count]: just like "z<CR>".

2. Scrolling upwards

scroll-up

The following commands move the edit window (the part of the buffer that you see) upwards (this means that more lines upwards in the text buffer can be seen):

CTRL-Y

CTRL-Y Scroll window [count] lines upwards in the buffer. The text moves downwards on the screen. **Note:** When using the MS-Windows key bindings CTRL-Y is remapped to redo.

CTRL-U

CTRL-U Scroll window Upwards in the buffer. The number of lines comes from the 'scroll' option (default: half a screen). If [count] given, first set the 'scroll' option to [count]. The cursor is moved the same number of lines up in the file (if possible; when lines wrap and when hitting the end of the file there may be a difference). When the cursor is on the first line of the buffer nothing happens and a beep is produced. See also 'startofline' option.

<S-Up> or <S-Up> <kPageUp>
<PageUp> or <PageUp> CTRL-B
<S--> or <S-Minus> SHIFT-MINUS

CTRL-B Scroll window [count] pages Backwards (upwards) in the buffer. See also 'startofline' option. When there is only one window the 'window' option might be used.

z^

z^ Without [count]: Redraw with the line just above the window at the bottom of the window. Put the cursor in that line, at the first non-blank in the line. With [count]: First scroll the text to put the [count] line at the bottom of the window, then redraw with the line which is now at the top of the window at the

bottom of the window. Put the cursor in that line, at the first non-blank in the line.

3. Scrolling relative to cursor *scroll-cursor*

The following commands reposition the edit window (the part of the buffer that you see) while keeping the cursor on the same line. Note that the 'scrolloff' option may cause context lines to show above and below the cursor.

z<CR>

z<CR> Redraw, line [count] at top of window (default cursor line). Put cursor at first non-blank in the line.

zt

zt Like "z<CR>", but leave the cursor in the same column.

zN<CR>

z{height}<CR> Redraw, make window {height} lines tall. This is useful to make the number of lines small when screen updating is very slow. Cannot make the height more than the physical screen height.

z.

z. Redraw, line [count] at center of window (default cursor line). Put cursor at first non-blank in the line.

zz

zz Like "z.", but leave the cursor in the same column. Careful: If caps-lock is on, this command becomes "ZZ": write buffer and exit!

z-

z- Redraw, line [count] at bottom of window (default cursor line). Put cursor at first non-blank in the line.

zb

zb Like "z-", but leave the cursor in the same column.

4. Scrolling horizontally *scroll-horizontal*

For the following four commands the cursor follows the screen. If the character that the cursor is on is moved off the screen, the cursor is moved to the closest character that is on the screen. The value of 'sidescroll' is not used.

z<Right> or *zl* *z<Right>*

zl Move the view on the text [count] characters to the right, thus scroll the text [count] characters to the left. This only works when 'wrap' is off.

z<Left> or *zh* *z<Left>*

zh Move the view on the text [count] characters to the left, thus scroll the text [count] characters to the right. This only works when 'wrap' is off.

zL

zL Move the view on the text half a screenwidth to the right, thus scroll the text half a screenwidth to the left. This only works when 'wrap' is off.

zH

zH Move the view on the text half a screenwidth to the left, thus scroll the text half a screenwidth to the right. This only works when 'wrap' is off.

For the following two commands the cursor is not moved in the text, only the text scrolls on the screen.

zs

zs Scroll the text horizontally to position the cursor at the start (left side) of the screen. This only works when 'wrap' is off.

ze

ze Scroll the text horizontally to position the cursor at the end (right side) of the screen. This only works when 'wrap' is off.

5. Scrolling synchronously *scroll-binding*

Occasionally, it is desirable to bind two or more windows together such that when one window is scrolled, the other windows are also scrolled. In Vim,

windows can be given this behavior by setting the (window-specific) 'scrollbind' option. When a window that has 'scrollbind' set is scrolled, all other 'scrollbind' windows are scrolled the same amount, if possible. The behavior of 'scrollbind' can be modified by the 'scrollopt' option.

When using the scrollbars or the mouse wheel, the binding only happens when scrolling the window with focus (where the cursor is). You can use this to avoid scroll-binding for a moment without resetting options.

When a window also has the 'diff' option set, the scroll-binding uses the differences between the two buffers to synchronize the position precisely. Otherwise the following method is used.

scrollbind-relative

Each 'scrollbind' window keeps track of its "relative offset", which can be thought of as the difference between the current window's vertical scroll position and the other window's vertical scroll position. When one of the 'scrollbind' windows is asked to vertically scroll past the beginning or end limit of its text, the window no longer scrolls, but remembers how far past the limit it wishes to be. The window keeps this information so that it can maintain the same relative offset, regardless of its being asked to scroll past its buffer's limits.

However, if a 'scrollbind' window that has a relative offset that is past its buffer's limits is given the cursor focus, the other 'scrollbind' windows must jump to a location where the current window's relative offset is valid. This behavior can be changed by clearing the "jump" flag from the 'scrollopt' option.

syncbind :syncbind :sync

:syncbind — Force all 'scrollbind' windows to have the same relative offset. I.e., when any of the 'scrollbind' windows is scrolled to the top of its buffer, all of the 'scrollbind' windows will also be at the top of their buffers.

scrollbind-quickadj

The 'scrollbind' flag is meaningful when using keyboard commands to vertically scroll a window, and is also meaningful when using the vertical scrollbar or the mouse wheel in the window which has the cursor focus. However, when using the vertical scrollbar or the mouse wheel in a window which doesn't have the cursor focus, 'scrollbind' is ignored.
This allows quick adjustment of the relative offset of 'scrollbind' windows.

6. Scrolling with a mouse wheel

scroll-mouse-wheel

When your mouse has a scroll wheel, it should work with Nvim in the GUI and any terminal that has mouse support. By default only vertical scroll wheels are supported, but some GUIs also support horizontal scroll wheels.

Note that horizontal scrolling only works if 'nowrap' is set. Also, unless the "h" flag in 'guioptions' is set, the cursor moves to the longest visible line if the cursor line is about to be scrolled off the screen (similarly to how the horizontal scrollbar works).

You can control the number of lines / columns to scroll by using the 'mousescroll' option. You can also modify the default behavior by mapping the keys. For example, to scroll a page at a time in normal mode:

```
:map <ScrollWheelUp> <C-B>
:map <ScrollWheelDown> <C-F>
```

Scroll keys can also be combined with modifiers such as Shift, Ctrl, and Alt.

When scrolling with a mouse, the window currently under the cursor is scrolled. This allows you to scroll inactive windows. Note that when scroll keys are remapped to keyboard keys, the active window is affected regardless of the current cursor position.

1. Introduction sign-intro signs gutter

When a debugger or other IDE tool is driving an editor it needs to be able to give specific highlights which quickly tell the user useful information about the file. One example of this would be a debugger which had an icon in the left-hand column denoting a breakpoint. Another example might be an arrow representing the Program Counter (PC). The sign features allow both placement of a sign, or icon, in the left-hand side of the window and definition of a highlight which will be applied to that line. Displaying the sign as an image is most likely only feasible in gvim (although Sun Microsystem's dtterm does support this it's the only terminal emulator I know of which does). A text sign and the highlight should be feasible in any color terminal emulator.

Signs and highlights are not useful just for debuggers. There are plugins that use signs to mark build errors or display version control status.

There are two steps in using signs:

1. Define the sign. This specifies the image, text and highlighting. For example, you can define a "break" sign with an image of a stop roadsign and text "!!".
2. Place the sign. This specifies the file and line number where the sign is displayed. A defined sign can be placed several times in different lines and files.

sign-column

When signs are defined for a file, Vim will automatically add a column of two characters to display them in. When the last sign is unplaced the column disappears again. This behavior can be changed with the 'signcolumn' option.

The color of the column is set with the SignColumn highlight group hl-SignColumn. Example to set the color:

```
:highlight SignColumn guibg=darkgrey
```

If 'cursorline' is enabled, then the CursorLineSign highlight group is used hl-CursorLineSign.

sign-identifier

Each placed sign is identified by a number called the sign identifier. This identifier is used to jump to the sign or to remove the sign. The identifier is assigned when placing the sign using the :sign-place command or the sign_place() function. Each sign identifier should be a unique number (per buffer). Placing the same identifier twice will move the previously placed sign. The sign_place() function can be called with a zero sign identifier to allocate the next available identifier.

sign-group

Each placed sign can be assigned to either the global group or a named group. When placing a sign, if a group name is not supplied, or an empty string is used, then the sign is placed in the global group. Otherwise the sign is placed in the named group. The sign identifier is unique within a group. The sign group allows Vim plugins to use unique signs without interfering with other plugins using signs.

sign-priority

Each placed sign is assigned a priority value independently of the sign group. The default priority for a sign is 10, this value can be changed for different signs by specifying a different value at definition time. When multiple signs that each have an icon or text are placed on the same line, signs are ordered with decreasing priority from left to right, up until the maximum width set in 'signcolumn'. Low priority signs that do not fit are hidden. Highest priority signs with highlight attributes are always shown.

When the line on which the sign is placed is deleted, the sign is removed along with it.

2. Commands sign-commands :sig :sign

Here is an example that places a sign "piet", displayed with the text ">>", in line 23 of the current file:

```
:sign define piet text=>> texthl=Search
:exe ":sign place 2 line=23 name=piet file=" .. expand("%:p")
```

And here is the command to delete it again:

```
:sign unplace 2
```

Note that the ":sign" command cannot be followed by another command or a

comment. If you do need that, use the :execute command.

DEFINING A SIGN. :sign-define E255 E160 E612

See sign_define() for the equivalent Vim script function.

:sig[n] define {name} {argument}...
Define a new sign or set attributes for an existing sign.
The {name} can either be a number (all digits) or a name
starting with a non-digit. Leading zeros are ignored, thus
"0012", "012" and "12" are considered the same name.
About 120 different signs can be defined.

Accepted arguments:

icon={bitmap}
Define the file name where the bitmap can be found. Should be
a full path. The bitmap should fit in the place of two
characters. This is not checked. If the bitmap is too big it
will cause redraw problems.

toolkit **supports**

Win32	.bmp, .ico, .cur

priority={prio}
Default priority for the sign, see sign-priority.

linehl={group}
Highlighting group used for the whole line the sign is placed
in. Most useful is defining a background color.

numhl={group}
Highlighting group used for the line number on the line where
the sign is placed. Combines with hl-LineNr,
hl-LineNrAbove, hl-LineNrBelow, and hl-CursorLineNr.

text={text} E239

Define the text that is displayed when there is no icon or the
GUI is not being used. Only printable characters are allowed
and they must occupy one or two display cells.

texthl={group}
Highlighting group used for the text item.

culhl={group}
Highlighting group used for the text item when the cursor is
on the same line as the sign and 'cursorline' is enabled.

Example:

```
:sign define MySign text=>> texthl=Search linehl=DiffText
```

DELETING A SIGN :sign-undefine E155

See sign_undefine() for the equivalent Vim script function.

:sig[n] undefine {name}
Deletes a previously defined sign. If signs with this {name}
are still placed this will cause trouble.

Example:

```
:sign undefine MySign
```

LISTING SIGNS :sign-list E156

See sign_getdefined() for the equivalent Vim script function.

:sig[n] list Lists all defined signs and their attributes.

:sig[n] list {name}
Lists one defined sign and its attributes.

PLACING SIGNS :sign-place E158

See sign_place() for the equivalent Vim script function.

:sig[n] place {id} line={lnum} name={name} file={fname}
Place sign defined as {name} at line {lnum} in file {fname}.
:sign-fname

The file {fname} must already be loaded in a buffer. The
exact file name must be used, wildcards, $ENV and ~ are not
expanded, white space must not be escaped. Trailing white
space is ignored.

The sign is remembered under {id}, this can be used for
further manipulation. {id} must be a number. Placing the
same {id} multiple times will move the sign.

The following optional sign attributes can be specified before
"file=":
group={group} Place sign in sign group {group}
priority={prio} Assign priority {prio} to sign

By default, the sign is placed in the global sign group.

By default, the sign is assigned a default priority of 10,
unless specified otherwise by the sign definition. To assign
a different priority value, use "priority={prio}" to specify a

value. The priority is used to determine the sign that is
displayed when multiple signs are placed on the same line.

Examples:

```
:sign place 5 line=3 name=sign1 file=a.py
:sign place 6 group=g2 line=2 name=sign2 file=x.py
:sign place 9 group=g2 priority=50 line=5
                              \ name=sign1 file=a.py
```

:sig[n] place {id} line={lnum} name={name} [buffer={nr}]
Same, but use buffer {nr}. If the buffer argument is not
given, place the sign in the current buffer.

Example:

```
:sign place 10 line=99 name=sign3
:sign place 10 line=99 name=sign3 buffer=3
```

E885

:sig[n] place {id} name={name} file={fname}
Change the placed sign {id} in file {fname} to use the defined
sign {name}. See remark above about {fname} :sign-fname.
This can be used to change the displayed sign without moving
it (e.g., when the debugger has stopped at a breakpoint).

The optional "group={group}" attribute can be used before
"file=" to select a sign in a particular group. The optional
"priority={prio}" attribute can be used to change the priority
of an existing sign.

Example:

```
:sign place 23 name=sign1 file=/path/to/edit.py
```

:sig[n] place {id} name={name} [buffer={nr}]
Same, but use buffer {nr}. If the buffer argument is not
given, use the current buffer.

Example:

```
:sign place 23 name=sign1
:sign place 23 name=sign1 buffer=7
```

REMOVING SIGNS :sign-unplace E159

See sign_unplace() for the equivalent Vim script function.

:sig[n] unplace {id} file={fname}
Remove the previously placed sign {id} from file {fname}.
See remark above about {fname} :sign-fname.

:sig[n] unplace {id} group={group} file={fname}
Same but remove the sign {id} in sign group {group}.

:sig[n] unplace {id} group=* file={fname}
Same but remove the sign {id} from all the sign groups.

:sig[n] unplace * file={fname}
Remove all placed signs in file {fname}.

:sig[n] unplace * group={group} file={fname}
Remove all placed signs in group {group} from file {fname}.

:sig[n] unplace * group=* file={fname}
Remove all placed signs in all the groups from file {fname}.

:sig[n] unplace {id} buffer={nr}
Remove the previously placed sign {id} from buffer {nr}.

:sig[n] unplace {id} group={group} buffer={nr}
Remove the previously placed sign {id} in group {group} from
buffer {nr}.

:sig[n] unplace {id} group=* buffer={nr}
Remove the previously placed sign {id} in all the groups from
buffer {nr}.

:sig[n] unplace * buffer={nr}
Remove all placed signs in buffer {nr}.

:sig[n] unplace * group={group} buffer={nr}
Remove all placed signs in group {group} from buffer {nr}.

:sig[n] unplace * group=* buffer={nr}
Remove all placed signs in all the groups from buffer {nr}.

:sig[n] unplace {id}
Remove the previously placed sign {id} from all files it
appears in.

:sig[n] unplace {id} group={group}
Remove the previously placed sign {id} in group {group} from
all files it appears in.

:sig[n] unplace {id} group=*
Remove the previously placed sign {id} in all the groups from
all the files it appears in.

:sig[n] unplace *
Remove all placed signs in the global group from all the

files.

:sig[n] unplace * group={group}
Remove all placed signs in group {group} from all the files.

:sig[n] unplace * group=*
Remove all placed signs in all the groups from all the files.

:sig[n] unplace
Remove a placed sign at the cursor position. If multiple signs are placed in the line, then only one is removed.

:sig[n] unplace group={group}
Remove a placed sign in group {group} at the cursor position.

:sig[n] unplace group=*
Remove a placed sign in any group at the cursor position.

LISTING PLACED SIGNS **:sign-place-list**

See sign_getplaced() for the equivalent Vim script function.

:sig[n] place file={fname}
List signs placed in file {fname}.
See remark above about {fname} :sign-fname.

:sig[n] place group={group} file={fname}
List signs in group {group} placed in file {fname}.

:sig[n] place group=* file={fname}
List signs in all the groups placed in file {fname}.

:sig[n] place buffer={nr}
List signs placed in buffer {nr}.

:sig[n] place group={group} buffer={nr}
List signs in group {group} placed in buffer {nr}.

:sig[n] place group=* buffer={nr}
List signs in all the groups placed in buffer {nr}.

:sig[n] place List placed signs in the global group in all files.

:sig[n] place group={group}
List placed signs with sign group {group} in all files.

:sig[n] place group=*
List placed signs in all sign groups in all files.

JUMPING TO A SIGN **:sign-jump** **E157**

See sign_jump() for the equivalent Vim script function.

:sig[n] jump {id} file={fname}
Open the file {fname} or jump to the window that contains {fname} and position the cursor at sign {id}.
See remark above about {fname} :sign-fname.
If the file isn't displayed in window and the current file can not be abandoned this fails.

:sig[n] jump {id} group={group} file={fname}
Same but jump to the sign in group {group}

:sig[n] jump {id} [buffer={nr}] E934

Same, but use buffer {nr}. This fails if buffer {nr} does not have a name. If the buffer argument is not given, use the current buffer.

:sig[n] jump {id} group={group} [buffer={nr}]
Same but jump to the sign in group {group}

3. Functions **sign-functions-details**

See:
- sign_define()

- sign_jump()
- sign_place()
- sign_placelist()
- sign_undefine()
- sign_unplace()

- sign_unplacelist()

Spell checking

1. Quick start

spell-quickstart E756

This command switches on spell checking:

```
:setlocal spell spelllang=en_us
```

This switches on the 'spell' option and specifies to check for US English.

The words that are not recognized are highlighted with one of these:

SpellBad	word not recognized	hl-SpellBad
SpellCap	word not capitalised	hl-SpellCap
SpellRare	rare word	hl-SpellRare
SpellLocal	wrong spelling for selected region	hl-SpellLocal

Vim only checks words for spelling, there is no grammar check.

If the 'mousemodel' option is set to "popup" and the cursor is on a badly spelled word or it is "popup_setpos" and the mouse pointer is on a badly spelled word, then the popup menu will contain a submenu to replace the bad word. **Note:** this slows down the appearance of the popup menu.

To search for the next misspelled word:

]s

]s Move to next misspelled word after the cursor.
A count before the command can be used to repeat.
'wrapscan' applies.

[s

[s Like "]s" but search backwards, find the misspelled word before the cursor. Doesn't recognize words split over two lines, thus may stop at words that are not highlighted as bad. Does not stop at word with missing capital at the start of a line.

]S

]S Like "]s" but only stop at bad words, not at rare words or words for another region.

[S

[S Like "]S" but search backwards.

]r

]r Move to next "rare" word after the cursor.
A count before the command can be used to repeat.
'wrapscan' applies.

[r

[r Like "]r" but search backwards, find the "rare" word before the cursor. Doesn't recognize words split over two lines, thus may stop at words that are not highlighted as rare.

To add words to your own word list:

zg

zg Add word under the cursor as a good word to the first name in 'spellfile'. A count may precede the command to indicate the entry in 'spellfile' to be used. A count of two uses the second entry.

In Visual mode the selected characters are added as a word (including white space!).
When the cursor is on text that is marked as badly spelled then the marked text is used.
Otherwise the word under the cursor, separated by non-word characters, is used.

If the word is explicitly marked as bad word in another spell file the result is unpredictable.

zG

zG Like "zg" but add the word to the internal word list internal-wordlist.

zw

zw Like "zg" but mark the word as a wrong (bad) word. If the word already appears in 'spellfile' it is turned into a comment line. See spellfile-cleanup for getting rid of those.

zW

zW Like "zw" but add the word to the internal word list internal-wordlist.

zuw zug zuw

zug Undo zw and zg, remove the word from the entry in 'spellfile'. Count used as with zg.

zuW zuG zuW

zuG Undo zW and zG, remove the word from the internal word list. Count used as with zg.

:spe :spellgood E1280

:[count]spe[llgood] {word}
Add {word} as a good word to 'spellfile', like with zg. Without count the first name is used, with a count of two the second entry, etc.

:spe[llgood]! {word} Add {word} as a good word to the internal word list, like with zG.

:spellw :spellwrong

:[count]spellw[rong] {word}
Add {word} as a wrong (bad) word to 'spellfile', as with zw. Without count the first name is used, with a count of two the second entry, etc.

:spellw[rong]! {word} Add {word} as a wrong (bad) word to the internal word list, like with zW.

:spellra :spellrare

:[count]spellra[re] {word}
Add {word} as a rare word to 'spellfile', similar to zw. Without count the first name is used, with a count of two the second entry, etc.

There are no normal mode commands to mark words as rare as this is a fairly uncommon command and all intuitive commands for this are already taken. If you want you can add mappings with e.g.:

```
nnoremap z?  :exe ':spellrare  ' .. expand('<cWORD>')<CR>
nnoremap z/  :exe ':spellrare! ' .. expand('<cWORD>')<CR>
```

:spellundo, zuw, or zuW can be used to undo this.

:spellra[re]! {word} Add {word} as a rare word to the internal word list, similar to zW.

:[count]spellu[ndo] {word} :spellu :spellundo
Like zuw. [count] used as with :spellgood.

:spellu[ndo]! {word} Like zuW. [count] used as with :spellgood.

After adding a word to 'spellfile' with the above commands its associated ".spl" file will automatically be updated and reloaded. If you change 'spellfile' manually you need to use the :mkspell command. This sequence of commands mostly works well:

```
:edit <file in 'spellfile'>

        (make changes to the spell file)

:mkspell! %
```

More details about the 'spellfile' format below spell-wordlist-format.

internal-wordlist

The internal word list is used for all buffers where 'spell' is set. It is not stored, it is lost when you exit Vim. It is also cleared when 'encoding' is set.

Finding suggestions for bad words:

z=

z= For the word under/after the cursor suggest correctly spelled words. This also works to find alternatives for a word that is not highlighted as a bad word, e.g., when the word after it is bad.
In Visual mode the highlighted text is taken as the word to be replaced.
The results are sorted on similarity to the word being replaced.
This may take a long time. Hit CTRL-C when you get bored.

If the command is used without a count the alternatives are listed and you can enter the number of your choice or press <Enter> if you don't want to replace. You can also use the mouse to click on your choice (only works if the mouse can be used in Normal mode and when there are no line wraps). Click on the first line (the header) to cancel.

The suggestions listed normally replace a highlighted bad word. Sometimes they include other text, in that case the replaced text is also listed after a "<".

If a count is used that suggestion is used, without prompting. For example, "1z=" always takes the first suggestion.

If 'verbose' is non-zero a score will be displayed
with the suggestions to indicate the likeliness to the
badly spelled word (the higher the score the more
different).
When a word was replaced the redo command "." will
repeat the word replacement. This works like "ciw",
the good word and <Esc>. This does NOT work for Thai
and other languages without spaces between words.

:spellr :spellrepall E752 E753

:spellr[epall] Repeat the replacement done by z= for all matches
with the replaced word in the current window.

In Insert mode, when the cursor is after a badly spelled word, you can use CTRL-X s to find suggestions. This works like Insert mode completion. Use CTRL-N to use the next suggestion, CTRL-P to go back. i_CTRL-X_s

The 'spellsuggest' option influences how the list of suggestions is generated and sorted. See 'spellsuggest'.

The 'spellcapcheck' option is used to check the first word of a sentence starts with a capital. When there is a line break right after a sentence the highlighting of the next line may be postponed. Use CTRL-L when needed. Also see set-spc-auto for how it can be set automatically when 'spelllang' is set.

The 'spelloptions' option has a few more flags that influence the way spell checking works. For example, "camel" splits CamelCased words so that each part of the word is spell-checked separately.

Vim counts the number of times a good word is encountered. This is used to sort the suggestions: words that have been seen before get a small bonus, words that have been seen often get a bigger bonus. The COMMON item in the affix file can be used to define common words, so that this mechanism also works in a new or short file spell-COMMON.

2. Remarks on spell checking spell-remarks

PERFORMANCE

Vim does on-the-fly spell checking. To make this work fast the word list is loaded in memory. Thus this uses a lot of memory (1 Mbyte or more). There might also be a noticeable delay when the word list is loaded, which happens when 'spell' is set and when 'spelllang' is set while 'spell' was already set. To minimize the delay each word list is only loaded once, it is not deleted when 'spelllang' is made empty or 'spell' is reset. When 'encoding' is set all the word lists are reloaded, thus you may notice a delay then too.

REGIONS

A word may be spelled differently in various regions. For example, English comes in (at least) these variants:

en	all regions
en_au	Australia
en_ca	Canada
en_gb	Great Britain
en_nz	New Zealand
en_us	USA

Words that are not used in one region but are used in another region are highlighted with SpellLocal hl-SpellLocal.

Always use lowercase letters for the language and region names.

When adding a word with zg or another command it's always added for all regions. You can change that by manually editing the 'spellfile'. See spell-wordlist-format. Note that the regions as specified in the files in 'spellfile' are only used when all entries in 'spelllang' specify the same region (not counting files specified by their .spl name).

spell-german

Specific exception: For German these special regions are used:

de	all German words accepted
de_de	old and new spelling
de_19	old spelling
de_20	new spelling
de_at	Austria
de_ch	Switzerland

spell-russian

Specific exception: For Russian these special regions are used:

ru	all Russian words accepted
ru_ru	"IE" letter spelling
ru_yo	"YO" letter spelling

spell-yiddish

Yiddish requires using "utf-8" encoding, because of the special characters used. If you are using latin1 Vim will use transliterated (romanized) Yiddish instead. If you want to use transliterated Yiddish with utf-8 use "yi-tr". In a table:

'encoding'	'spelllang'	
utf-8	yi	Yiddish

latin1	yi	transliterated Yiddish
utf-8	yi-tr	transliterated Yiddish

spell-cjk

Chinese, Japanese and other East Asian characters are normally marked as errors, because spell checking of these characters is not supported. If 'spelllang' includes "cjk", these characters are not marked as errors. This is useful when editing text with spell checking while some Asian words are present.

SPELL FILES

spell-load

Vim searches for spell files in the "spell" subdirectory of the directories in 'runtimepath'. The name is: LL.EEE.spl, where:

LL	the language name
EEE	the value of 'encoding'

The value for "LL" comes from 'spelllang', but excludes the region name. Examples:

'spelllang'	LL
en_us	en
en-rare	en-rare
medical_ca	medical

Only the first file is loaded, the one that is first in 'runtimepath'. If this succeeds then additionally files with the name LL.EEE.add.spl are loaded. All the ones that are found are used.

Additionally, the files related to the names in 'spellfile' are loaded. These are the files that zg and zw add good and wrong words to.

Exceptions:

- Vim uses "latin1" when 'encoding' is "iso-8859-15". The euro sign doesn't matter for spelling.
- When no spell file for 'encoding' is found "ascii" is tried. This only works for languages where nearly all words are ASCII, such as English. It helps when 'encoding' is not "latin1", such as iso-8859-2, and English text is being edited. For the ".add" files the same name as the found main spell file is used.

For example, with these values:

```
'runtimepath' is "~/.config/nvim,/usr/share/nvim/runtime/,~/.config/nvim/after"
'encoding'    is "iso-8859-2"
'spelllang'   is "pl"
```

Vim will look for:

1. ~/.config/nvim/spell/pl.iso-8859-2.spl
2. /usr/share/nvim/runtime/spell/pl.iso-8859-2.spl
3. ~/.config/nvim/spell/pl.iso-8859-2.add.spl
4. /usr/share/nvim/runtime/spell/pl.iso-8859-2.add.spl
5. ~/.config/nvim/after/spell/pl.iso-8859-2.add.spl

This assumes 1. is not found and 2. is found.

If 'encoding' is "latin1" Vim will look for:

1. ~/.config/nvim/spell/pl.latin1.spl
2. /usr/share/nvim/runtime/spell/pl.latin1.spl
3. ~/.config/nvim/after/spell/pl.latin1.spl
4. ~/.config/nvim/spell/pl.ascii.spl
5. /usr/share/nvim/runtime/spell/pl.ascii.spl
6. ~/.config/nvim/after/spell/pl.ascii.spl

This assumes none of them are found (Polish doesn't make sense when leaving out the non-ASCII characters).

A spell file might not be available in the current 'encoding'. See spell-mkspell about how to create a spell file. Converting a spell file with "iconv" will NOT work!

spell-sug-file E781

If there is a file with exactly the same name as the ".spl" file but ending in ".sug", that file will be used for giving better suggestions. It isn't loaded before suggestions are made to reduce memory use.

E758 E759 E778 E779 E780 E782 E5042

When loading a spell file Vim checks that it is properly formatted. If you get an error the file may be truncated, modified or intended for another Vim version.

SPELLFILE CLEANUP spellfile-cleanup

The zw command turns existing entries in 'spellfile' into comment lines. This avoids having to write a new file every time, but results in the file only getting longer, never shorter. To clean up the comment lines in all ".add" spell files do this:

```
:runtime spell/cleanadd.vim
```

This deletes all comment lines, except the ones that start with "##". Use "##" lines to add comments that you want to keep.

You can invoke this script as often as you like. A variable is provided to skip updating files that have been changed recently. Set it to the number of seconds that has passed since a file was changed before it will be cleaned. For example, to clean only files that were not changed in the last hour:

```
let g:spell_clean_limit = 60 * 60
```

The default is one second.

WORDS

Vim uses a fixed method to recognize a word. This is independent of 'iskeyword', so that it also works in help files and for languages that include characters like '-' in 'iskeyword'. The word characters do depend on 'encoding'.

The table with word characters is stored in the main .spl file. Therefore it matters what the current locale is when generating it! A .add.spl file does not contain a word table though.

For a word that starts with a digit the digit is ignored, unless the word as a whole is recognized. Thus if "3D" is a word and "D" is not then "3D" is recognized as a word, but if "3D" is not a word then only the "D" is marked as bad. Hex numbers in the form 0x12ab and 0X12AB are recognized.

WORD COMBINATIONS

It is possible to spell-check words that include a space. This is used to recognize words that are invalid when used by themselves, e.g. for "et al.". It can also be used to recognize "the the" and highlight it.

The number of spaces is irrelevant. In most cases a line break may also appear. However, this makes it difficult to find out where to start checking for spelling mistakes. When you make a change to one line and only that line is redrawn Vim won't look in the previous line, thus when "et" is at the end of the previous line "al." will be flagged as an error. And when you type "the<CR>the" the highlighting doesn't appear until the first line is redrawn. Use CTRL-L to redraw right away. "[s" will also stop at a word combination with a line break.

When encountering a line break Vim skips characters such as "*", '>' and '"', so that comments in C, shell and Vim code can be spell checked.

SYNTAX HIGHLIGHTING spell-syntax

Files that use syntax highlighting can specify where spell checking should be done:

1.	everywhere	default
2.	in specific items	use "contains=@Spell"
3.	everywhere but specific items	use "contains=@NoSpell"

For the second method adding the @NoSpell cluster will disable spell checking again. This can be used, for example, to add @Spell to the comments of a program, and add @NoSpell for items that shouldn't be checked.
Also see :syn-spell for text that is not in a syntax item.

VIM SCRIPTS

If you want to write a Vim script that does something with spelling, you may find these functions useful:

spellbadword()	find badly spelled word at the cursor
spellsuggest()	get list of spelling suggestions
soundfold()	get the sound-a-like version of a word

SETTING 'spellcapcheck' AUTOMATICALLY set-spc-auto

After the 'spelllang' option has been set successfully, Vim will source the files "spell/LANG.vim" and "spell/LANG.lua" in 'runtimepath'. "LANG" is the value of 'spelllang' up to the first comma, dot or underscore. This can be used to set options specifically for the language, especially 'spellcapcheck'.

The distribution includes a few of these files. Use this command to see what they do:

```
:next $VIMRUNTIME/spell/*.vim
```

Note that the default scripts don't set 'spellcapcheck' if it was changed from the default value. This assumes the user prefers another value then.

DOUBLE SCORING spell-double-scoring

The 'spellsuggest' option can be used to select "double" scoring. This mechanism is based on the principle that there are two kinds of spelling mistakes:

1. You know how to spell the word, but mistype something. This results in a small editing distance (character swapped/omitted/inserted) and possibly a word that sounds completely different.
2. You don't know how to spell the word and type something that sounds right. The edit distance can be big but the word is similar after sound-folding.

Since scores for these two mistakes will be very different we use a list for each and mix them.

The sound-folding is slow and people that know the language won't make the second kind of mistakes. Therefore 'spellsuggest' can be set to select the preferred method for scoring the suggestions.

3. Generating a spell file spell-mkspell

Vim uses a binary file format for spelling. This greatly speeds up loading the word list and keeps it small.

.aff .dic Myspell

You can create a Vim spell file from the .aff and .dic files that Myspell uses. Myspell is used by OpenOffice.org and Mozilla. The OpenOffice .oxt files are zip files which contain the .aff and .dic files. You should be able to find them here:

https://extensions.openoffice.org/en/search@f%5B0%5D%3Dfield_project_tags%253A311.html

The older, OpenOffice 2 files may be used if this doesn't work:

http://wiki.services.openoffice.org/wiki/Dictionaries

You can also use a plain word list. The results are the same, the choice depends on what word lists you can find.

Make sure your current locale is set properly, otherwise Vim doesn't know what characters are upper/lower case letters. If the locale isn't available (e.g., when using an MS-Windows codepage on Unix) add tables to the .aff file spell-affix-chars. If the .aff file doesn't define a table then the word table of the currently active spelling is used. If spelling is not active then Vim will try to guess.

:mksp :mkspell

:mksp[ell][!] [-ascii] {outname} {inname} ...
Generate a Vim spell file from word lists. Example:

```
:mkspell /tmp/nl nl_NL.words
```

E751

When {outname} ends in ".spl" it is used as the output file name. Otherwise it should be a language name, such as "en", without the region name. The file written will be "{outname}.{encoding}.spl", where {encoding} is the value of the 'encoding' option.

When the output file already exists [!] must be used to overwrite it.

When the [-ascii] argument is present, words with non-ascii characters are skipped. The resulting file ends in "ascii.spl".

The input can be the Myspell format files {inname}.aff and {inname}.dic. If {inname}.aff does not exist then {inname} is used as the file name of a plain word list.

Multiple {inname} arguments can be given to combine regions into one Vim spell file. Example:

```
:mkspell ~/.config/nvim/spell/en /tmp/en_US /tmp/en_CA /tmp/en_AU
```

This combines the English word lists for US, CA and AU into one en.spl file.
Up to eight regions can be combined. E754 E755
The REP and SAL items of the first .aff file where

they appear are used. spell-REP spell-SAL

E845

This command uses a lot of memory, required to find the optimal word tree (Polish, Italian and Hungarian require several hundred Mbyte). The final result will be much smaller, because compression is used. To avoid running out of memory compression will be done now and then. This can be tuned with the 'mkspellmem' option.

E1578

There is a limit on how many postponed prefix and compound flags can be stored for one word. Reduce the number of affix/compound flags on a word in the .dic file that exceeds it.

After the spell file was written and it was being used in a buffer it will be reloaded automatically.

:mksp[ell] [-ascii] {name}.{enc}.add
Like ":mkspell" above, using {name}.{enc}.add as the input file and producing an output file in the same directory that has ".spl" appended.

:mksp[ell] [-ascii] {name}
Like ":mkspell" above, using {name} as the input file and producing an output file in the same directory that has ".{enc}.spl" appended.

Vim will report the number of duplicate words. This might be a mistake in the list of words. But sometimes it is used to have different prefixes and suffixes for the same basic word to avoid them combining (e.g. Czech uses this). If you want Vim to report all duplicate words set the 'verbose' option.

Since you might want to change a Myspell word list for use with Vim the following procedure is recommended:

1. Obtain the xx_YY.aff and xx_YY.dic files from Myspell.

2. Make a copy of these files to xx_YY.orig.aff and xx_YY.orig.dic.

3. Change the xx_YY.aff and xx_YY.dic files to remove bad words, add missing words, define word characters with FOL/LOW/UPP, etc. The distributed "*.diff" files can be used.

4. Start Vim with the right locale and use :mkspell to generate the Vim spell file.

5. Try out the spell file with ":set spell spelllang=xx" if you wrote it in a spell directory in 'runtimepath', or ":set spelllang=xx.enc.spl" if you wrote it somewhere else.

When the Myspell files are updated you can merge the differences:

1. Obtain the new Myspell files as xx_YY.new.aff and xx_UU.new.dic.

2. Use diff-mode to see what changed:

```
nvim -d xx_YY.orig.dic xx_YY.new.dic
```

3. Take over the changes you like in xx_YY.dic. You may also need to change xx_YY.aff.

4. Rename xx_YY.new.dic to xx_YY.orig.dic and xx_YY.new.aff to xx_YY.orig.aff.

SPELL FILE VERSIONS

E770 E771 E772

Spell checking is a relatively new feature in Vim, thus it's possible that the .spl file format will be changed to support more languages. Vim will check the validity of the spell file and report anything wrong.

E771: Old spell file, needs to be updated
This spell file is older than your Vim. You need to update the .spl file.

E772: Spell file is for newer version of Vim
This means the spell file was made for a later version of Vim. You need to update Vim.

E770: Unsupported section in spell file
This means the spell file was made for a later version of Vim and contains a section that is required for the spell file to work. In this case it's probably a good idea to upgrade your Vim.

SPELL FILE DUMP

If for some reason you want to check what words are supported by the currently used spelling files, use this command:

:spelldump :spelld

:spelld[ump] Open a new window and fill it with all currently valid words. Compound words are not included.
Note: For some languages the result may be enormous, causing Vim to run out of memory.

:spelld[ump]! Like ":spelldump" and include the word count. This is the number of times the word was found while updating the screen. Words that are in COMMON items get a starting count of 10.

The format of the word list is used spell-wordlist-format. You should be able to read it with ":mkspell" to generate one .spl file that includes all the words.

When all entries to 'spelllang' use the same regions or no regions at all then the region information is included in the dumped words. Otherwise only words for the current region are included and no "/regions" line is generated.

Comment lines with the name of the .spl file are used as a header above the words that were generated from that .spl file.

SPELL FILE MISSING spell-SpellFileMissing

If a spell file is missing, the user is asked whether to download it. See package-spellfile.

E797

Note that the SpellFileMissing autocommand must not change or destroy the buffer the user was editing.

4. Spell file format spell-file-format

This is the format of the files that are used by the person who creates and maintains a word list.

Note that we avoid the word "dictionary" here. That is because the goal of spell checking differs from writing a dictionary (as in the book). For spelling we need a list of words that are OK, thus should not be highlighted. Person and company names will not appear in a dictionary, but do appear in a word list. And some old words are rarely used while they are common misspellings. These do appear in a dictionary but not in a word list.

There are two formats: A straight list of words and a list using affix compression. The files with affix compression are used by Myspell (Mozilla and OpenOffice.org). This requires two files, one with .aff and one with .dic extension.

FORMAT OF STRAIGHT WORD LIST spell-wordlist-format

The words must appear one per line. That is all that is required.

Additionally the following items are recognized:

- Empty and blank lines are ignored.

comment
- Lines starting with a # are ignored (comment lines).

/encoding=utf-8
- A line starting with "/encoding=", before any word, specifies the encoding

  of the file. After the second '=' comes an encoding name. This tells Vim to setup conversion from the specified encoding to 'encoding'. Thus you can use one word list for several target encodings.

/regions=usca
- A line starting with "/regions=" specifies the region names that are

  supported. Each region name must be two ASCII letters. The first one is region 1. Thus "/regions=usca" has region 1 "us" and region 2 "ca". In an addition word list the region names should be equal to the main word list!
- Other lines starting with '/' are reserved for future use. The ones that

  are not recognized are ignored. You do get a warning message, so that you know something won't work.
- A "/" may follow the word with the following items:

  = Case must match exactly.
  ? Rare word.
  ! Bad (wrong) word.

1 to 9 A region in which the word is valid. If no regions are specified the word is valid in all regions.

Example:

```
# This is an example word list          comment
/encoding=latin1                        encoding of the file
/regions=uscagb                         regions "us", "ca" and "gb"
example                                 word for all regions
blah/12                                 word for regions "us" and "ca"
vim/!                                   bad word
Campbell/?3                             rare word in region 3 "gb"
's mornings/=                           keep-case word
```

Note that when "/=" is used the same word with all upper-case letters is not accepted. This is different from a word with mixed case that is automatically marked as keep-case, those words may appear in all upper-case letters.

FORMAT WITH .AFF AND .DIC FILES aff-dic-format

There are two files: the basic word list and an affix file. The affix file specifies settings for the language and can contain affixes. The affixes are used to modify the basic words to get the full word list. This significantly reduces the number of words, especially for a language like Polish. This is called affix compression.

The basic word list and the affix file are combined with the ":mkspell" command and results in a binary spell file. All the preprocessing has been done, thus this file loads fast. The binary spell file format is described in the source code (src/spell.c). But only developers need to know about it.

The preprocessing also allows us to take the Myspell language files and modify them before the Vim word list is made. The tools for this can be found in the "src/spell" directory.

The format for the affix and word list files is based on what Myspell uses (the spell checker of Mozilla and OpenOffice.org). A description can be found here:

https://lingucomponent.openoffice.org/affix.readme

Note that affixes are case sensitive, this isn't obvious from the description.

Vim supports quite a few extras. They are described below spell-affix-vim. Attempts have been made to keep this compatible with other spell checkers, so that the same files can often be used. One other project that offers more than Myspell is Hunspell (https://hunspell.github.io).

WORD LIST FORMAT spell-dic-format

A short example, with line numbers:

```
1                                       1234
2 aan
3 Als
4 Etten-Leur
5 et al.
6 's-Gravenhage
7 's-Gravenhaags
8 # word that differs between regions
9 kado/1
10 cadeau/2
11 TCP,IP
12 /the S affix may add a 's'
13 bedel/S
```

The first line contains the number of words. Vim ignores it, but you do get an error message if it's not there. E760

What follows is one word per line. White space at the end of the line is ignored, all other white space matters. The encoding is specified in the affix file spell-SET.

Comment lines start with '#' or '/'. See the example lines 8 and 12. Note that putting a comment after a word is NOT allowed:

```
someword   # comment that causes an error!
```

After the word there is an optional slash and flags. Most of these flags are letters that indicate the affixes that can be used with this word. These are specified with SFX and PFX lines in the .aff file, see spell-SFX and spell-PFX. Vim allows using other flag types with the FLAG item in the affix file spell-FLAG.

When the word only has lower-case letters it will also match with the word starting with an upper-case letter.

When the word includes an upper-case letter, this means the upper-case letter is required at this position. The same word with a lower-case letter at this position will not match. When some of the other letters are upper-case it will not match either.

The word with all upper-case characters will always be OK,

word list	matches	does not match
als	als Als ALS	ALs AlS aLs aLS
Als	Als ALS	als ALs AlS aLs aLS
ALS	ALS	als Als ALs AlS aLs aLS
AlS	AlS ALS	als Als ALs aLs aLS

The KEEPCASE affix ID can be used to specifically match a word with identical case only, see below spell-KEEPCASE.

Note: in line 5 to 7 non-word characters are used. You can include any character in a word. When checking the text a word still only matches when it appears with a non-word character before and after it. For Myspell a word starting with a non-word character probably won't work.

In line 12 the word "TCP/IP" is defined. Since the slash has a special meaning the comma is used instead. This is defined with the SLASH item in the affix file, see spell-SLASH. Note that without this SLASH item the word will be "TCP,IP".

AFFIX FILE FORMAT

spell-aff-format spell-affix-vim

spell-affix-comment

Comment lines in the .aff file start with a '#':

```
# comment line
```

Items with a fixed number of arguments can be followed by a comment. But only if none of the arguments can contain white space. The comment must start with a "#" character. Example:

```
KEEPCASE =  # fix case for words with this flag
```

ENCODING

spell-SET

The affix file can be in any encoding that is supported by "iconv". However, in some cases the current locale should also be set properly at the time :mkspell is invoked. Adding FOL/LOW/UPP lines removes this requirement spell-FOL.

The encoding should be specified before anything where the encoding matters. The encoding applies both to the affix file and the dictionary file. It is done with a SET line:

```
SET utf-8
```

The encoding can be different from the value of the 'encoding' option at the time ":mkspell" is used. Vim will then convert everything to 'encoding' and generate a spell file for 'encoding'. If some of the used characters to not fit in 'encoding' you will get an error message.

spell-affix-mbyte

When using a multibyte encoding it's possible to use more different affix flags. But Myspell doesn't support that, thus you may not want to use it anyway. For compatibility use an 8-bit encoding.

INFORMATION

These entries in the affix file can be used to add information to the spell file. There are no restrictions on the format, but they should be in the right encoding.

spell-NAME spell-VERSION spell-HOME
spell-AUTHOR spell-EMAIL spell-COPYRIGHT

```
NAME            Name of the language
VERSION         1.0.1  with fixes
HOME            https://www.example.com
AUTHOR          John Doe
EMAIL           john AT Doe DOT net
COPYRIGHT       LGPL
```

These fields are put in the .spl file as-is. The :spellinfo command can be used to view the info.

:spellinfo :spelli

```
:spelli[nfo]            Display the information for the spell file(s) used for
                        the current buffer.
```

CHARACTER TABLES

spell-affix-chars

When using an 8-bit encoding the affix file should define what characters are word characters. This is because the system where ":mkspell" is used may not support a locale with this encoding and isalpha() won't work. For example when using "cp1250" on Unix.

E761 E762 spell-FOL
spell-LOW spell-UPP

Three lines in the affix file are needed. Simplistic example:

```
FOL  áëñ
LOW  áëñ
UPP  ÁËÑ
```

All three lines must have exactly the same number of characters.

The "FOL" line specifies the case-folded characters. These are used to compare words while ignoring case. For most encodings this is identical to the lower case line.

The "LOW" line specifies the characters in lower-case. Mostly it's equal to the "FOL" line.

The "UPP" line specifies the characters with upper-case. That is, a character is upper-case where it's different from the character at the same position in "FOL".

An exception is made for the German sharp s ß. The upper-case version is "SS". In the FOL/LOW/UPP lines it should be included, so that it's recognized as a word character, but use the ß character in all three.

ASCII characters should be omitted, Vim always handles these in the same way. When the encoding is UTF-8 no word characters need to be specified.

E763

Vim allows you to use spell checking for several languages in the same file. You can list them in the 'spelllang' option. As a consequence all spell files for the same encoding must use the same word characters, otherwise they can't be combined without errors.

If you get an E763 warning that the word tables differ you need to update your ".spl" spell files. If you downloaded the files, get the latest version of all spell files you use. If you are only using one, e.g., German, then also download the recent English spell files. Otherwise generate the .spl file again with :mkspell. If you still get errors check the FOL, LOW and UPP lines in the used .aff files.

The XX.ascii.spl spell file generated with the "-ascii" argument will not contain the table with characters, so that it can be combine with spell files for any encoding. The .add.spl files also do not contain the table.

MID-WORD CHARACTERS

spell-midword

Some characters are only to be considered word characters if they are used in between two ordinary word characters. An example is the single quote: It is often used to put text in quotes, thus it can't be recognized as a word character, but when it appears in between word characters it must be part of the word. This is needed to detect a spelling error such as they'are. That should be they're, but since "they" and "are" are words themselves that would go unnoticed.

These characters are defined with MIDWORD in the .aff file. Example:

```
MIDWORD '-
```

FLAG TYPES

spell-FLAG

Flags are used to specify the affixes that can be used with a word and for other properties of the word. Normally single-character flags are used. This limits the number of possible flags, especially for 8-bit encodings. The FLAG item can be used if more affixes are to be used. Possible values:

```
FLAG long       use two-character flags
FLAG num        use numbers, from 1 up to 65000
FLAG caplong    use one-character flags without A-Z and two-character
                flags that start with A-Z
```

With "FLAG num" the numbers in a list of affixes need to be separated with a comma: "234,2143,1435". This method is inefficient, but useful if the file is generated with a program.

When using "caplong" the two-character flags all start with a capital: "Aa", "B1", "BB", etc. This is useful to use one-character flags for the most common items and two-character flags for uncommon items.

Note: When using utf-8 only characters up to 65000 may be used for flags.

Note: even when using "num" or "long" the number of flags available to compounding and prefixes is limited to about 250.

AFFIXES

spell-PFX spell-SFX

The usual PFX (prefix) and SFX (suffix) lines are supported (see the Myspell documentation or the Aspell manual: http://aspell.net/man-html/Affix-Compression.html).

Summary:

```
SFX L Y 2
SFX L 0 re [^x]
SFX L 0 ro x
```

The first line is a header and has four fields:

```
SFX {flag} {combine} {count}
```

{flag} The name used for the suffix. Mostly it's a single letter, but other characters can be used, see spell-FLAG.

{combine} Can be 'Y' or 'N'. When 'Y' then the word plus suffix can also have a prefix. When 'N' then a prefix is not allowed.

{count} The number of lines following. If this is wrong you will get an error message.

For PFX the fields are exactly the same.

The basic format for the following lines is:

```
SFX {flag} {strip} {add} {condition} {extra}
```

{flag} Must be the same as the {flag} used in the first line.

{strip} Characters removed from the basic word. There is no check if the characters are actually there, only the length is used (in bytes). This better match the {condition}, otherwise strange things may happen. If the {strip} length is equal to or longer than the basic word the suffix won't be used. When {strip} is 0 (zero) then nothing is stripped.

{add} Characters added to the basic word, after removing {strip}. Optionally there is a '/' followed by flags. The flags apply to the word plus affix. See spell-affix-flags

{condition} A simplistic pattern. Only when this matches with a basic word will the suffix be used for that word. This is normally for using one suffix letter with different {add} and {strip} fields for words with different endings. When {condition} is a . (dot) there is no condition. The pattern may contain:

- Literal characters.
- A set of characters in []. [abc] matches a, b and c. A dash is allowed for a range [a-c], but this is Vim-specific.
- A set of characters that starts with a ^, meaning the complement of the specified characters. [^abc] matches any character but a, b and c.

{extra} Optional extra text:

```
# comment           Comment is ignored
-                   Hunspell uses this, ignored
```

For PFX the fields are the same, but the {strip}, {add} and {condition} apply to the start of the word.

Note: Myspell ignores any extra text after the relevant info. Vim requires this text to start with a "#" so that mistakes don't go unnoticed. Example:

```
SFX F 0 in   [^i]n      # Spion > Spionin
SFX F 0 nen  in         # Bauerin > Bauerinnen
```

However, to avoid lots of errors in affix files written for Myspell, you can add the IGNOREEXTRA flag.

Apparently Myspell allows an affix name to appear more than once. Since this might also be a mistake, Vim checks for an extra "S". The affix files for Myspell that use this feature apparently have this flag. Example:

```
SFX a Y 1 S
SFX a 0 an .

SFX a Y 2 S
SFX a 0 en .
SFX a 0 on .
```

AFFIX FLAGS spell-affix-flags

This is a feature that comes from Hunspell: The affix may specify flags. This works similar to flags specified on a basic word. The flags apply to the basic word plus the affix (but there are restrictions). Example:

```
SFX S Y 1
SFX S 0 s .

SFX A Y 1
SFX A 0 able/S .
```

When the dictionary file contains "drink/AS" then these words are possible:

```
drink
drinks          uses S suffix
drinkable       uses A suffix
drinkables      uses A suffix and then S suffix
```

Generally the flags of the suffix are added to the flags of the basic word, both are used for the word plus suffix. But the flags of the basic word are only used once for affixes, except that both one prefix and one suffix can be used when both support combining.

Specifically, the affix flags can be used for:

- Suffixes on suffixes, as in the example above. This works once, thus you can have two suffixes on a word (plus one prefix).
- Making the word with the affix rare, by using the spell-RARE flag.
- Exclude the word with the affix from compounding, by using the spell-COMPOUNDFORBIDFLAG flag.

- Allow the word with the affix to be part of a compound word on the side of the affix with the spell-COMPOUNDPERMITFLAG.
- Use the NEEDCOMPOUND flag: word plus affix can only be used as part of a compound word. spell-NEEDCOMPOUND
- Compound flags: word plus affix can be part of a compound word at the end, middle, start, etc. The flags are combined with the flags of the basic word. spell-compound
- NEEDAFFIX: another affix is needed to make a valid word.

- CIRCUMFIX, as explained just below.

IGNOREEXTRA spell-IGNOREEXTRA

Normally Vim gives an error for an extra field that does not start with '#'. This avoids errors going unnoticed. However, some files created for Myspell or Hunspell may contain many entries with an extra field. Use the IGNOREEXTRA flag to avoid lots of errors.

CIRCUMFIX spell-CIRCUMFIX

The CIRCUMFIX flag means a prefix and suffix must be added at the same time. If a prefix has the CIRCUMFIX flag then only suffixes with the CIRCUMFIX flag can be added, and the other way around.
An alternative is to only specify the suffix, and give that suffix two flags: the required prefix and the NEEDAFFIX flag. spell-NEEDAFFIX

PFXPOSTPONE spell-PFXPOSTPONE

When an affix file has very many prefixes that apply to many words it's not possible to build the whole word list in memory. This applies to Hebrew (a list with all words is over a Gbyte). In that case applying prefixes must be postponed. This makes spell checking slower. It is indicated by this keyword in the .aff file:

PFXPOSTPONE

Only prefixes without a chop string and without flags can be postponed. Prefixes with a chop string or with flags will still be included in the word list. An exception if the chop string is one character and equal to the last character of the added string, but in lower case. Thus when the chop string is used to allow the following word to start with an upper case letter.

WORDS WITH A SLASH spell-SLASH

The slash is used in the .dic file to separate the basic word from the affix letters and other flags. Unfortunately, this means you cannot use a slash in a word. Thus "TCP/IP" is not a word but "TCP" with the flags "IP". To include a slash in the word put a backslash before it: "TCP\/IP". In the rare case you want to use a backslash inside a word you need to use two backslashes.
Any other use of the backslash is reserved for future expansion.

KEEP-CASE WORDS spell-KEEPCASE

In the affix file a KEEPCASE line can be used to define the affix name used for keep-case words. Example:

KEEPCASE =

This flag is not supported by Myspell. It has the meaning that case matters. This can be used if the word does not have the first letter in upper case at the start of a sentence. Example:

word list	matches	does not match
's morgens/= 's morgens	'S morgens 's Morgens 'S MORGENS	
's Morgens	's Morgens 'S MORGENS 'S morgens 's morgens	

The flag can also be used to avoid that the word matches when it is in all upper-case letters.

RARE WORDS spell-RARE

In the affix file a RARE line can be used to define the affix name used for rare words. Example:

RARE ?

Rare words are highlighted differently from bad words. This is to be used for words that are correct for the language, but are hardly ever used and could be a typing mistake anyway.

This flag can also be used on an affix, so that a basic word is not rare but the basic word plus affix is rare spell-affix-flags. However, if the word also appears as a good word in another way (e.g., in another region) it won't be marked as rare.

BAD WORDS

spell-BAD

In the affix file a BAD line can be used to define the affix name used for bad words. Example:

BAD !

This can be used to exclude words that would otherwise be good. For example "the the" in the .dic file:

the the/!

Once a word has been marked as bad it won't be undone by encountering the same word as good.

The flag also applies to the word with affixes, thus this can be used to mark a whole bunch of related words as bad.

spell-FORBIDDENWORD

FORBIDDENWORD can be used just like BAD. For compatibility with Hunspell.

spell-NEEDAFFIX

The NEEDAFFIX flag is used to require that a word is used with an affix. The word itself is not a good word (unless there is an empty affix). Example:

NEEDAFFIX +

COMPOUND WORDS

spell-compound

A compound word is a longer word made by concatenating words that appear in the .dic file. To specify which words may be concatenated a character is used. This character is put in the list of affixes after the word. We will call this character a flag here. Obviously these flags must be different from any affix IDs used.

spell-COMPOUNDFLAG

The Myspell compatible method uses one flag, specified with COMPOUNDFLAG. All words with this flag combine in any order. This means there is no control over which word comes first. Example:
COMPOUNDFLAG c

spell-COMPOUNDRULE

A more advanced method to specify how compound words can be formed uses multiple items with multiple flags. This is not compatible with Myspell 3.0. Let's start with an example:
COMPOUNDRULE c+
COMPOUNDRULE se

The first line defines that words with the "c" flag can be concatenated in any order. The second line defines compound words that are made of one word with the "s" flag and one word with the "e" flag. With this dictionary:
bork/c
onion/s
soup/e

You can make these words:
```
        bork
        borkbork
        borkborkbork
        (etc.)
        onion
        soup
        onionsoup
```

The COMPOUNDRULE item may appear multiple times. The argument is made out of one or more groups, where each group can be:
```
        one flag                        e.g., c
        alternate flags inside []       e.g., [abc]
```
Optionally this may be followed by:
```
        *       the group appears zero or more times, e.g., sm*e
        +       the group appears one or more times, e.g., c+
        ?       the group appears zero times or once, e.g., x?
```

This is similar to the regexp pattern syntax (but not the same!). A few examples with the sequence of word flags they require:
```
    COMPOUNDRULE x+         x xx xxx etc.
    COMPOUNDRULE yz         yz
    COMPOUNDRULE x+z        xz xxz xxxz etc.
    COMPOUNDRULE yx+        yx yxx yxxx etc.
    COMPOUNDRULE xy?z       xz xyz

    COMPOUNDRULE [abc]z    az bz cz
    COMPOUNDRULE [abc]+z   az aaz abaz bz baz bcbz cz caz cbaz etc.
    COMPOUNDRULE a[xyz]+   ax axx axyz ay ayx ayzz az azy azxy etc.
    COMPOUNDRULE sm*e       se sme smme smmme etc.
    COMPOUNDRULE s[xyz]*e  se sxe sxye sxyxe sye syze sze szye szyxe  etc.
```

A specific example: Allow a compound to be made of two words and a dash:
        In the .aff file:
COMPOUNDRULE sde
NEEDAFFIX x
COMPOUNDWORDMAX 3
COMPOUNDMIN 1
        In the .dic file:
start/s

end/e
-/xd

This allows for the word "start-end", but not "startend".

An additional implied rule is that, without further flags, a word with a prefix cannot be compounded after another word, and a word with a suffix cannot be compounded with a following word. Thus the affix cannot appear on the inside of a compound word. This can be changed with the spell-COMPOUNDPERMITFLAG.

spell-NEEDCOMPOUND

The NEEDCOMPOUND flag is used to require that a word is used as part of a compound word. The word itself is not a good word. Example:

NEEDCOMPOUND &

spell-ONLYINCOMPOUND

The ONLYINCOMPOUND does exactly the same as NEEDCOMPOUND. Supported for compatibility with Hunspell.

spell-COMPOUNDMIN

The minimal character length of a word used for compounding is specified with COMPOUNDMIN. Example:
COMPOUNDMIN 5

When omitted there is no minimal length. Obviously you could just leave out the compound flag from short words instead, this feature is present for compatibility with Myspell.

spell-COMPOUNDWORDMAX

The maximum number of words that can be concatenated into a compound word is specified with COMPOUNDWORDMAX. Example:
COMPOUNDWORDMAX 3

When omitted there is no maximum. It applies to all compound words.

To set a limit for words with specific flags make sure the items in COMPOUNDRULE where they appear don't allow too many words.

spell-COMPOUNDSYLMAX

The maximum number of syllables that a compound word may contain is specified with COMPOUNDSYLMAX. Example:
COMPOUNDSYLMAX 6

This has no effect if there is no SYLLABLE item. Without COMPOUNDSYLMAX there is no limit on the number of syllables.

If both COMPOUNDWORDMAX and COMPOUNDSYLMAX are defined, a compound word is accepted if it fits one of the criteria, thus is either made from up to COMPOUNDWORDMAX words or contains up to COMPOUNDSYLMAX syllables.

spell-COMPOUNDFORBIDFLAG

The COMPOUNDFORBIDFLAG specifies a flag that can be used on an affix. It means that the word plus affix cannot be used in a compound word. Example:
affix file:
COMPOUNDFLAG c
COMPOUNDFORBIDFLAG x
SFX a Y 2
SFX a 0 s .
SFX a 0 ize/x .
dictionary:
word/c
util/ac

This allows for "wordutil" and "wordutils" but not "wordutilize".
Note: this doesn't work for postponed prefixes yet.

spell-COMPOUNDPERMITFLAG

The COMPOUNDPERMITFLAG specifies a flag that can be used on an affix. It means that the word plus affix can also be used in a compound word in a way where the affix ends up halfway through the word. Without this flag that is not allowed.
Note: this doesn't work for postponed prefixes yet.

spell-COMPOUNDROOT

The COMPOUNDROOT flag is used for words in the dictionary that are already a compound. This means it counts for two words when checking the compounding rules. Can also be used for an affix to count the affix as a compounding word.

spell-CHECKCOMPOUNDPATTERN

CHECKCOMPOUNDPATTERN is used to define patterns that, when matching at the position where two words are compounded together forbids the compound.
For example:
CHECKCOMPOUNDPATTERN o e

This forbids compounding if the first word ends in "o" and the second word starts with "e".

The arguments must be plain text, no patterns are actually supported, despite the item name. Case is always ignored.

The Hunspell feature to use three arguments and flags is not supported.

spell-NOCOMPOUNDSUGS

This item indicates that using compounding to make suggestions is not a good idea. Use this when compounding is used with very short or one-character words. E.g. to make numbers out of digits. Without this flag creating suggestions would spend most time trying all kind of weird compound words.

NOCOMPOUNDSUGS

spell-SYLLABLE

The SYLLABLE item defines characters or character sequences that are used to count the number of syllables in a word. Example:
SYLLABLE aáeéiíoóöõuúüûy/aa/au/ea/ee/ei/ie/oa/oe/oo/ou/uu/ui

Before the first slash is the set of characters that are counted for one syllable, also when repeated and mixed, until the next character that is not in this set. After the slash come sequences of characters that are counted for one syllable. These are preferred over using characters from the set. With the example "ideeen" has three syllables, counted by "i", "ee" and "e".

Only case-folded letters need to be included.

Another way to restrict compounding was mentioned above: Adding the spell-COMPOUNDFORBIDFLAG flag to an affix causes all words that are made with that affix to not be used for compounding.

UNLIMITED COMPOUNDING

spell-NOBREAK

For some languages, such as Thai, there is no space in between words. This looks like all words are compounded. To specify this use the NOBREAK item in the affix file, without arguments:
NOBREAK

Vim will try to figure out where one word ends and a next starts. When there are spelling mistakes this may not be quite right.

spell-COMMON

Common words can be specified with the COMMON item. This will give better suggestions when editing a short file. Example:

COMMON the of to and a in is it you that he she was for on are

The words must be separated by white space, up to 25 per line.
When multiple regions are specified in a ":mkspell" command the common words for all regions are combined and used for all regions.

spell-NOSPLITSUGS

This item indicates that splitting a word to make suggestions is not a good idea. Split-word suggestions will appear only when there are few similar words.

NOSPLITSUGS

spell-NOSUGGEST

The flag specified with NOSUGGEST can be used for words that will not be suggested. Can be used for obscene words.

NOSUGGEST %

REPLACEMENTS

spell-REP

In the affix file REP items can be used to define common mistakes. This is used to make spelling suggestions. The items define the "from" text and the "to" replacement. Example:

```
REP 4
REP f ph
REP ph f
REP k ch
REP ch k
```

The first line specifies the number of REP lines following. Vim ignores the number, but it must be there (for compatibility with Myspell).

Don't include simple one-character replacements or swaps. Vim will try these anyway. You can include whole words if you want to, but you might want to use the "file:" item in 'spellsuggest' instead.

You can include a space by using an underscore:

REP the_the the

SIMILAR CHARACTERS

spell-MAP **E783**

In the affix file MAP items can be used to define letters that are very much alike. This is mostly used for a letter with different accents. This is used to prefer suggestions with these letters substituted. Example:

```
MAP 2
MAP eéëêè
MAP uüùúû
```

The first line specifies the number of MAP lines following. Vim ignores the number, but the line must be there.

Each letter must appear in only one of the MAP items. It's a bit more efficient if the first letter is ASCII or at least one without accents.

.SUG FILE

spell-NOSUGFILE

When soundfolding is specified in the affix file then ":mkspell" will normally produce a .sug file next to the .spl file. This file is used to find suggestions by their sound-a-like form quickly. At the cost of a lot of memory (the amount depends on the number of words, :mkspell will display an estimate when it's done).

To avoid producing a .sug file use this item in the affix file:

NOSUGFILE

Users can simply omit the .sug file if they don't want to use it.

SOUND-A-LIKE

spell-SAL

In the affix file SAL items can be used to define the sounds-a-like mechanism to be used. The main items define the "from" text and the "to" replacement. Simplistic example:

```
SAL CIA      X

SAL CH X
SAL C K
SAL K K
```

There are a few rules and this can become quite complicated. An explanation how it works can be found in the Aspell manual:
http://aspell.net/man-html/Phonetic-Code.html.

There are a few special items:

```
SAL followup                 true

SAL collapse_result true
SAL remove_accents true
```

"1" has the same meaning as "true". Any other value means "false".

SIMPLE SOUNDFOLDING

spell-SOFOFROM spell-SOFOTO

The SAL mechanism is complex and slow. A simpler mechanism is mapping all characters to another character, mapping similar sounding characters to the same character. At the same time this does case folding. You can not have both SAL items and simple soundfolding.

There are two items required: one to specify the characters that are mapped and one that specifies the characters they are mapped to. They must have exactly the same number of characters. Example:

```
SOFOFROM abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ
SOFOTO   ebctefghejklnnepkrstevvkesebctefghejklnnepkrstevvkes
```

In the example all vowels are mapped to the same character 'e'. Another method would be to leave out all vowels. Some characters that sound nearly the same and are often mixed up, such as 'm' and 'n', are mapped to the same character. Don't do this too much, all words will start looking alike.

Characters that do not appear in SOFOFROM will be left out, except that all white space is replaced by one space. Sequences of the same character in SOFOFROM are replaced by one.

You can use the soundfold() function to try out the results. Or set the 'verbose' option to see the score in the output of the z= command.

UNSUPPORTED ITEMS

spell-affix-not-supported

These items appear in the affix file of other spell checkers. In Vim they are ignored, not supported or defined in another way.

ACCENT (Hunspell) spell-ACCENT

Use MAP instead. spell-MAP

BREAK (Hunspell) spell-BREAK

Define break points. Unclear how it works exactly.
Not supported.

CHECKCOMPOUNDCASE (Hunspell) spell-CHECKCOMPOUNDCASE

Disallow uppercase letters at compound word boundaries.
Not supported.

CHECKCOMPOUNDDUP (Hunspell) spell-CHECKCOMPOUNDDUP

Disallow using the same word twice in a compound. Not supported.

CHECKCOMPOUNDREP (Hunspell) spell-CHECKCOMPOUNDREP

Something about using REP items and compound words. Not supported.

CHECKCOMPOUNDTRIPLE (Hunspell) spell-CHECKCOMPOUNDTRIPLE

Forbid three identical characters when compounding. Not supported.

CHECKSHARPS (Hunspell) spell-CHECKSHARPS

SS letter pair in uppercased (German) words may be upper case
sharp s (ß). Not supported.

COMPLEXPREFIXES (Hunspell) spell-COMPLEXPREFIXES

Enables using two prefixes. Not supported.

COMPOUND (Hunspell) spell-COMPOUND

This is one line with the count of COMPOUND items, followed by
that many COMPOUND lines with a pattern.
Remove the first line with the count and rename the other
items to COMPOUNDRULE spell-COMPOUNDRULE

COMPOUNDFIRST (Hunspell) spell-COMPOUNDFIRST

Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDBEGIN (Hunspell) spell-COMPOUNDBEGIN

Words signed with COMPOUNDBEGIN may be first elements in
compound words.
Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDLAST (Hunspell) spell-COMPOUNDLAST

Words signed with COMPOUNDLAST may be last elements in
compound words.
Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDEND (Hunspell) spell-COMPOUNDEND

Probably the same as COMPOUNDLAST

COMPOUNDMIDDLE (Hunspell) spell-COMPOUNDMIDDLE

Words signed with COMPOUNDMIDDLE may be middle elements in
compound words.
Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDRULES (Hunspell) spell-COMPOUNDRULES

Number of COMPOUNDRULE lines following. Ignored, but the
argument must be a number.

COMPOUNDSYLLABLE (Hunspell) spell-COMPOUNDSYLLABLE

Use SYLLABLE and COMPOUNDSYLMAX instead. spell-SYLLABLE
spell-COMPOUNDSYLMAX

KEY (Hunspell) spell-KEY

Define characters that are close together on the keyboard.
Used to give better suggestions. Not supported.

LANG (Hunspell) spell-LANG

This specifies language-specific behavior. This actually
moves part of the language knowledge into the program,
therefore Vim does not support it. Each language property
must be specified separately.

LEMMA_PRESENT (Hunspell) spell-LEMMA_PRESENT

Only needed for morphological analysis.

MAXNGRAMSUGS (Hunspell) spell-MAXNGRAMSUGS

Set number of n-gram suggestions. Not supported.

PSEUDOROOT (Hunspell) spell-PSEUDOROOT

Use NEEDAFFIX instead. spell-NEEDAFFIX

SUGSWITHDOTS (Hunspell) spell-SUGSWITHDOTS

Adds dots to suggestions. Vim doesn't need this.

SYLLABLENUM (Hunspell) spell-SYLLABLENUM

Not supported.

TRY (Myspell, Hunspell, others) spell-TRY

Vim does not use the TRY item, it is ignored. For making
suggestions the actual characters in the words are used, that
is much more efficient.

WORDCHARS (Hunspell) spell-WORDCHARS

Used to recognize words. Vim doesn't need it, because there
is no need to separate words before checking them (using a
trie instead of a hashtable).

5. Spell checker design develop-spell

When spell checking was going to be added to Vim a survey was done over the
available spell checking libraries and programs. Unfortunately, the result
was that none of them provided sufficient capabilities to be used as the spell
checking engine in Vim, for various reasons:

- Missing support for multi-byte encodings. At least UTF-8 must be supported,
  so that more than one language can be used in the same file.
  Doing on-the-fly conversion is not always possible (would require iconv
  support).
- For the programs and libraries: Using them as-is would require installing
  them separately from Vim. That's mostly not impossible, but a drawback.
- Performance: A few tests showed that it's possible to check spelling on the
  fly (while redrawing), just like syntax highlighting. But the mechanisms
  used by other code are much slower. Myspell uses a hashtable, for example.
  The affix compression that most spell checkers use makes it slower too.
- For using an external program like aspell a communication mechanism would
  have to be setup. That's complicated to do in a portable way (Unix-only
  would be relatively simple, but that's not good enough). And performance
  will become a problem (lots of process switching involved).
- Missing support for words with non-word characters, such as "Etten-Leur" and
  "et al.", would require marking the pieces of them OK, lowering the
  reliability.
- Missing support for regions or dialects. Makes it difficult to accept
  all English words and highlight non-Canadian words differently.
- Missing support for rare words. Many words are correct but hardly ever used
  and could be a misspelled often-used word.
- For making suggestions the speed is less important and requiring to install
  another program or library would be acceptable. But the word lists probably
  differ, the suggestions may be wrong words.

Spelling suggestions develop-spell-suggestions

For making suggestions there are two basic mechanisms:
1. Try changing the bad word a little bit and check for a match with a good
   word. Or go through the list of good words, change them a little bit and
   check for a match with the bad word. The changes are deleting a character,
   inserting a character, swapping two characters, etc.
2. Perform soundfolding on both the bad word and the good words and then find
   matches, possibly with a few changes like with the first mechanism.

The first is good for finding typing mistakes. After experimenting with
hashtables and looking at solutions from other spell checkers the conclusion
was that a trie (a kind of tree structure) is ideal for this. Both for
reducing memory use and being able to try sensible changes. For example, when
inserting a character only characters that lead to good words need to be
tried. Other mechanisms (with hashtables) need to try all possible letters at
every position in the word. Also, a hashtable has the requirement that word
boundaries are identified separately, while a trie does not require this.
That makes the mechanism a lot simpler.

Soundfolding is useful when someone knows how the words sounds but doesn't
know how it is spelled. For example, the word "dictionary" might be written
as "daktonerie". The number of changes that the first method would need to
try is very big, it's hard to find the good word that way. After soundfolding
the words become "tktnr" and "tkxnry", these differ by only two letters.

To find words by their soundfolded equivalent (soundalike word) we need a list
of all soundfolded words. A few experiments have been done to find out what
the best method is. Alternatives:
1. Do the sound folding on the fly when looking for suggestions. This means
   walking through the trie of good words, soundfolding each word and
   checking how different it is from the bad word. This is very efficient for
   memory use, but takes a long time. On a fast PC it takes a couple of
   seconds for English, which can be acceptable for interactive use. But for
   some languages it takes more than ten seconds (e.g., German, Catalan),
   which is unacceptable slow. For batch processing (automatic corrections)
   it's too slow for all languages.
2. Use a trie for the soundfolded words, so that searching can be done just
   like how it works without soundfolding. This requires remembering a list
   of good words for each soundfolded word. This makes finding matches very
   fast but requires quite a lot of memory, in the order of 1 to 10 Mbyte.
   For some languages more than the original word list.

3. Like the second alternative, but reduce the amount of memory by using affix
   compression and store only the soundfolded basic word. This is what Aspell
   does. Disadvantage is that affixes need to be stripped from the bad word
   before soundfolding it, which means that mistakes at the start and/or end
   of the word will cause the mechanism to fail. Also, this becomes slow when
   the bad word is quite different from the good word.

The choice made is to use the second mechanism and use a separate file. This way a user with sufficient memory can get very good suggestions while a user who is short of memory or just wants the spell checking and no suggestions doesn't use so much memory.

Word frequency

For sorting suggestions it helps to know which words are common. In theory we could store a word frequency with the word in the dictionary. However, this requires storing a count per word. That degrades word tree compression a lot. And maintaining the word frequency for all languages will be a heavy task. Also, it would be nice to prefer words that are already in the text. This way the words that appear in the specific text are preferred for suggestions.

What has been implemented is to count words that have been seen during displaying. A hashtable is used to quickly find the word count. The count is initialized from words listed in COMMON items in the affix file, so that it also works when starting a new file.

This isn't ideal, because the longer Vim is running the higher the counts become. But in practice it is a noticeable improvement over not using the word count.

Nvim arguments

cli-arguments

Most often, Nvim is started to edit a single file with the command:

```
nvim filename
```

More generally, Nvim is started with:

```
nvim [option | filename] ..
```

Option arguments and file name arguments can be mixed, and any number of them can be given. However, watch out for options that take an argument.

The following items decide how to start editing:

-file --- filename One or more file names. The first one will be the current file and read into the buffer. The cursor will be positioned on the first line of the buffer. To avoid a file name starting with a '-' being interpreted as an option, precede the arglist with "--", e.g.:

```
nvim -- -filename
```

All arguments after "--" are interpreted as file names, no other options or "+command" arguments can follow.

--

- Alias for stdin (standard input). Example:

```
echo text | nvim - file
```

"text" is read into buffer 1, "file" is opened as buffer 2. In most cases (except -s, -es, --embed, --headless) if stdin is not a TTY then it is read as text, so "-" is implied:

```
echo text | nvim file
```

The buffer will be marked as modified, because it contains text that needs to be saved (except for readonly -R mode). If you don't like that, put these lines in your init.vim:

```
" Don't set 'modified' when reading from stdin
au StdinReadPost * set nomodified
```

To read stdin as Normal commands use -s with "-":

```
echo "ifoo" | nvim -s -
```

To read stdin as Ex commands use -es or -e:

```
echo "echo getpid()" | nvim -e - -V1
```

To open a file literally named "-", put it after "--":

```
echo foo | nvim -- -
```

To read stdin as text with --headless use "-".

-t -tag -t {tag} A tag. "tag" is looked up in the tags file, the associated file becomes the current file, and the associated command is executed. Mostly this is used for C programs, in which case "tag" often is a function name. The effect is that the file containing that function becomes the current file and the cursor is positioned on the start of the function (see tags).

-q -qf -q [errorfile] QuickFix mode. The file with the name [errorfile] is read and the first error is displayed. See quickfix. If [errorfile] is not given, the 'errorfile' option is used for the file name. See 'errorfile' for the default value.

(nothing) Without one of the four items above, Vim will start editing a new buffer. It's empty and doesn't have a file name.

startup-options

The option arguments may be given in any order. Single-letter options can be combined after one dash. There can be no option arguments after the "--" argument.

--help -h --help -? -? -h Give usage (help) message and exit.

--version -v --version -v Print version information and exit. Same output as for :version command.

--clean

--clean Mimics a fresh install of Nvim:

- Skips initializations from files and environment variables.
- No 'shada' file is read or written.
- Excludes user directories from 'runtimepath'
- Loads builtin plugins, unlike "-u NONE -i NONE".

--noplugin

--noplugin Skip loading plugins. Resets the 'loadplugins' option. Note that the -u argument may also disable loading plugins: argument load vimrc files load plugins

```
(nothing)               yes                yes
-u NONE                 no                 no
-u NORC                 no                 yes
--noplugin              yes                no
```

--startuptime {fname} --startuptime
During startup write timing messages to the file {fname}. This can be used to find out where time is spent while loading your config, plugins and opening the first file. When {fname} already exists new messages are appended.

-+
+[num] The cursor will be positioned on line "num" for the first file being edited. If "num" is missing, the cursor will be positioned on the last line.

-+/
+/{pat} The cursor will be positioned on the first line containing "pat" in the first file being edited (see pattern for the available search patterns). The search starts at the cursor position, which can be the first line or the cursor position last used from shada. To force a search from the first line use "+1 +/pat".

+{command} -+c -c -c {command} {command} will be executed after the first file has been read (and after autocommands and modelines for that file have been processed). "command" is interpreted as an Ex command. If the "command" contains spaces, it must be enclosed in double quotes (this depends on the shell that is used). Example:

```
vim  "+set si"  main.c
vim  "+find stdio.h"
vim  -c "set ff=dos"  -c wq  mine.mak
```

Note: You can use up to 10 "+" or "-c" arguments in a Vim command. They are executed in the order given. A "-S" argument counts as a "-c" argument as well.

--cmd {command} --cmd
{command} will be executed before processing any vimrc file. Otherwise, it acts like -c {command}. You can use up to 10 of these commands, independently from "-c" commands.

-S
-S [file] Executes Vimscript or Lua (".lua") [file] after the first file has been read. See also :source. If [file] is not given, defaults to "Session.vim". Equivalent to:

```
-c "source {file}"
```

Can be repeated like "-c", subject to the same limit of 10 "-c" arguments. {file} cannot start with a "-".

-L -L -r -r Recovery mode. Without a file name argument, a list of existing swap files is given. With a file name, a swap file is read to recover a crashed editing session. See crash-recovery.

-R
-R Readonly mode. The 'readonly' option will be set for all the files being edited. You can still edit the buffer, but will be prevented from accidentally overwriting a file. If you forgot that you are in View mode and did make some changes, you can overwrite a file by adding an exclamation mark to the Ex command, as in ":w!". The 'readonly' option can be reset with ":set noro" (see the options chapter, options). Subsequent edits will not be done in readonly mode. The 'updatecount' option will be set to 10000, meaning that the swap file will not be updated automatically very often. See -M for disallowing modifications.

-m
-m Modifications not allowed to be written. The 'write' option will be reset, so that writing files is disabled. However, the 'write' option can be set to enable writing again.

-M
-M Modifications not allowed. The 'modifiable' option will be reset, so that changes are not allowed. The 'write' option will be reset, so that writing files is disabled. However, the 'modifiable' and 'write' options can be set to enable changes and writing.

-e -e -E -E Start Nvim in Ex-mode.

If stdin is not a TTY:
- -e reads/executes stdin as Ex commands.
- -E reads stdin as text (into buffer 1).

-es -es -Es -s-ex silent-mode -Es Script mode, aka "silent mode", aka "batch mode". No UI, disables most prompts and messages. Unrelated to -s. See also -S to run script files.

-es reads/executes stdin as Ex commands.

```
printf "put ='foo'\n%%print\n" | nvim -es
```

-Es reads stdin as text (into buffer 1). Use -c or "+" to send commands.

```
printf "foo\n" | nvim -Es +"%print"
```

These commands display on stdout:
- :list
- :number
- :print
- :set

With :verbose or 'verbose', other commands display on stderr:

```
nvim -es +"verbose echo 'foo'"
nvim -V1 -es +"echo 'foo'"
```

Commands that wait for typed input (input(), getchar(), ...) stop Nvim on EOF; they do not consume stdin. Lua can read stdin as data:

```
printf 'lua vim.g.b = io.read()\nfoo\nput =g:b\np' | nvim -es
```

Skips user config unless -u was given. Disables shada unless -i was given. Disables swapfile (like -n).

-l

-l {script} [args] Executes Lua {script} non-interactively (no UI) with optional [args] after processing any preceding Nvim cli-arguments, then exits. Exits 1 on Lua error. See -S to run multiple Lua scripts without args, with a UI.

lua-args

All [args] are treated as {script} arguments and stored in the Lua _G.arg global table, thus "-l" ends processing of Nvim arguments. The {script} name is stored at _G.arg[0].

Sets 'verbose' to 1 (like "-V1"), so Lua print() writes to output, as well as other message-emitting functions like :echo. If {script} prints messages and doesn't cause Nvim to exit, Nvim ensures output ends with a newline.

Arguments before "-l" are processed before executing {script}. This example quits before executing "foo.lua":

```
nvim +q -l foo.lua
```

This loads Lua module "bar" before executing "foo.lua":

```
nvim +"lua require('bar')" -l foo.lua
```

lua-shebang

You can set the "shebang" of the script so that Nvim executes the script when called with "./" from a shell (remember to "chmod u+x"):

```
#!/usr/bin/env -S nvim -l
```

Skips user config unless -u was given. Disables plugins unless 'loadplugins' was set. Disables shada unless -i was given. Disables swapfile (like -n).

-b

-b Binary mode. File I/O will only recognize <NL> to separate lines. The 'expandtab' option will be reset. The 'textwidth' option is set to 0. 'modeline' is reset. The 'binary' option is set. This is done after reading the vimrc but before reading any file in the arglist. See also edit-binary.

-A

-A Arabic mode. Sets the 'arabic' option on.

-H

-H Hebrew mode. Sets the 'rightleft' option on and the 'keymap' option to "hebrew".

-V verbose -V[N] Verbose. Sets the 'verbose' option to [N] (default: 10). Messages will be given for each file that is ":source"d and for reading or writing a ShaDa file. Can be used to find out what is happening upon startup and exit. Example:

```
nvim -V8
```

-V[N]{file} Like -V and sets 'verbosefile' to {file} (must not start with a digit). Messages are not displayed, instead they are written to {file}. Example:

```
nvim -V20vimlog
```

-D

-D Debugging. Go to debugging mode when executing the first command from a script. debug-mode

-n

-n Disables swap-file by setting 'updatecount' to 0 (after executing any vimrc). Recovery after a crash will be impossible. Improves performance when working with a file on a very slow medium (usb drive, network share).

Enable it again by setting 'updatecount' to some value, e.g. ":set updatecount=100".

To reduce accesses to the disk, don't use "-n", but set 'updatetime' and 'updatecount' to very big numbers, and type ":preserve" when you want to save your work. This way you keep the possibility for crash recovery.

-o

-o[N] Open N windows, split horizontally. If [N] is not given, one window is opened for every file given as argument. If there is not enough room, only the first few files get a window. If there are more windows than arguments, the last few windows will be editing an empty file.

-O

-O[N] Open N windows, split vertically. Otherwise, it's like -o. If both the -o and the -O option are given, the last one on the command line determines how the windows will be split.

-p

-p[N] Open N tabpages. If [N] is not given, one tabpage is opened for every file given as argument. The maximum is set with 'tabpagemax' pages (default 50). If there are more tabpages than arguments, the last few tabpages will be editing an empty file. Also see tabpage.

-d

-d Start in diff-mode.

-u E282 -u {vimrc} The file {vimrc} is read for initializations. Most other initializations are skipped; see initialization.

This can be used to start Vim in a special mode, with special mappings and settings. A shell alias can be used to make this easy to use. For example, in a C shell descendant:

```
alias vimc 'nvim -u ~/.config/nvim/c_init.vim \!*'
```

And in a Bash shell:

```
alias vimc='nvim -u ~/.config/nvim/c_init.vim'
```

Also consider using autocommands; see autocommand.

When {vimrc} is "NONE" (all uppercase), all initializations from files and environment variables are skipped. Plugins and syntax highlighting are also skipped.

When {vimrc} is "NORC" (all uppercase), this has the same effect as "NONE", but plugins and syntax highlighting are not skipped.

-i

-i {shada} The file {shada} is used instead of the default ShaDa file. If the name "NONE" is used (all uppercase), no ShaDa file is read or written, even if 'shada' is set or when ":rsh" or ":wsh" are used. See also shada-file.

-s

-s {scriptin} Read script file {scriptin}, interpreting characters as Normal-mode input. The same can be done with ":source!":

```
:source! {scriptin}
```

Reads from stdin if {scriptin} is "-":

```
echo "ifoo" | nvim -s -
```

If the end of the file is reached before Nvim exits, further characters are read from the keyboard.

Does not work with -es. See also complex-repeat.

-w_nr

-w {number} -w{number} Set the 'window' option to {number}.

-w

-w {scriptout} All keys that you type are recorded in the file "scriptout", until you exit Vim. Useful to create a script file to be used with "vim -s" or ":source!". Appends to the "scriptout" file if it already exists. {scriptout} cannot start with a digit. See also vim.on_key(). See also complex-repeat.

-W

-W {scriptout} Like -w, but do not append, overwrite an existing file.

--api-info

--api-info Print msgpack-encoded api-metadata and exit.

--embed

--embed Use stdin/stdout as a msgpack-RPC channel, so applications can embed and control Nvim via the RPC API. Nvim exits if the channel is closed, unless the channel was detached (:detach, :detach!, nvim_chan_set()) or another detach=false channel is still open.

Waits for a client to call nvim_ui_attach() before sourcing startup files and reading buffers, so UIs can display early messages/dialogs and make preliminary requests (e.g. nvim_chan_set to set channel config, or nvim_get_api_info for feature-detection). During this pre-startup phase the user config is of course not available (similar to --cmd).

Non-UI embedders must pass --headless, then startup will continue without waiting for nvim_ui_attach:

```
nvim --embed --headless
```

which is equivalent to:

```
nvim --headless --cmd "call stdioopen({'rpc': v:true})"
```

UI embedders that want the UI protocol on a socket (instead of stdio) must pass --listen as well as --embed:

```
nvim --embed --listen addr
```

Then stdin is an RPC channel only if it is a pipe/socket. Otherwise (tty, /dev/null) Nvim waits for a UI to attach at addr, e.g. to start a server for a GUI on a remote host:

```
ssh host 'nvim --embed --listen 0.0.0.0:8888 &'
```

The UI can call nvim_chan_set() with detach=false to enable exit-on-channel-close behavior.

To "daemonize" such a server, use jobstart() with "detach":

```
nvim -es +"lua vim.fn.jobstart({'nvim', '--embed', '--listen', 'addr'}, {detach=true, stdin='null'})" +q
```

See also: ui-startup channel-stdio

--headless

--headless Start without UI, and do not wait for nvim_ui_attach. The builtin TUI is not used, so stdio works as an arbitrary communication channel. channel-stdio

Also useful for scripting (tests) to see messages that would not be printed by -es.

To detect if a UI is available, check if nvim_list_uis() is empty during or after VimEnter.

To read stdin as text, "-" must be given explicitly: --headless cannot assume that stdin is just text.

```
echo foo | nvim --headless +"%print" +"q!" -
```

See also --embed. See also -es, which also disables most messages.

--listen {addr} --listen
Start RPC server on pipe or TCP address {addr}. Sets the primary listen address v:servername to {addr}. serverstart()

To start the server on-demand with systemd, use a systemd socket unit and associated service unit running:

```
systemd-socket-proxyd --exit-idle-time
```

Initialization initialization startup

At startup, Nvim checks environment variables and files and sets values accordingly, proceeding as follows:

1. Set v:starttime and v:startreason.

2. Set the 'shell' option. SHELL COMSPEC The environment variable SHELL, if it exists, is used to set the 'shell' option. On Win32, the COMSPEC variable is used if SHELL is not set.
3. Process the arguments. The options and file names from the command that start Vim are inspected. The -V argument can be used to display or log what happens next, useful for debugging the initializations. The --cmd arguments are executed. Buffers are created for all files (but not loaded yet).
4. Start a server (unless --listen was given) and set v:servername.
5. Wait for UI to connect. Nvim started with --embed waits for the UI to connect before proceeding to load user configuration.
6. Setup default-mappings and default-autocmds. Create popup-menu.
7. Enable filetype and indent plugins. Skipped if the "-u NONE" command line argument was given. This does the same as:

```
:runtime! ftplugin.vim indent.vim
```

8. Load user config (execute Ex commands from files, environment, ...). $VIMINIT environment variable is read as one Ex command line (separate multiple commands with '|' or <NL>). config init.vim init.lua vimrc exrc
   - A file containing initialization commands is generically called a "vimrc" or config file. It can be Vimscript ("init.vim") or Lua ("init.lua"), but not both. E5422 See vimrc-intro base-directories. The config file is located at:
     - Unix ~/.config/nvim/init.vim (or init.lua)
     - Windows ~/AppData/Local/nvim/init.vim (or init.lua)
     - $XDG_CONFIG_HOME $XDG_CONFIG_HOME/nvim/init.vim (or init.lua)
   - If Nvim was started with "-u `{file}`" then `{file}` is used as the config and all initializations until 8. are skipped. $MYVIMRC is not set. "nvim -u NORC" can be used to skip these initializations without reading a file. "nvim -u NONE" also skips plugins and syntax highlighting. -u
   - If Nvim was started with -es or -Es or -l all initializations until "8" are skipped.
   - a. system-vimrc sysinit.vim The system vimrc file is read for initializations. If nvim/sysinit.vim file exists in one of $XDG_CONFIG_DIRS, it will be used. Otherwise the system vimrc file is used. The path of this file is given by the :version command. Usually it's "$VIM/sysinit.vim".
   - b. VIMINIT EXINIT $MYVIMRC Locations searched for initializations, in order of preference. $MYVIMRC is set to the first valid location unless it was already set or when using $VIMINIT:
     - $VIMINIT environment variable (Ex command line).
     - User config: $XDG_CONFIG_HOME/nvim/init.vim (or init.lua).
     - Other config: `{dir}`/nvim/init.vim (or init.lua) where `{dir}` is any directory in $XDG_CONFIG_DIRS.
     - $EXINIT environment variable (Ex command line).
   - c. If the 'exrc' option is on, the current-directory is searched until one of these files is found, in order of precedence:
     - ".nvim.lua"
     - ".nvimrc"
     - ".exrc"
9. Enable filetype detection. Skipped if ":filetype off" was called or if the "-u NONE" command line argument was given. This does the same as:

```
:runtime! filetype.lua
```

10. Enable syntax highlighting. Skipped if ":syntax off" was called or if the "-u NONE" command line argument was given. This does the same as:

```
:runtime! syntax/syntax.vim
```

11. Set the v:vim_did_init variable to 1.
12. Load the plugin scripts. load-plugins
    This does the same as: `:runtime! plugin/**/*.{vim,lua}`
    - The result is that all directories in 'runtimepath' will be searched for the "plugin" sub-directory and all files ending in ".vim" or ".lua" will be sourced (in alphabetical order per directory), also in subdirectories. First "*.vim" are sourced, then "*.lua" files, per directory.
    - However, directories in 'runtimepath' ending in "after" are skipped here and only loaded after packages, see below.
    - Loading plugins won't be done when:
      - The 'loadplugins' option was reset in a vimrc file.
      - The --noplugin command line argument is used.
      - The --clean command line argument is used.
      - The "-u NONE" command line argument is used -u.
    - Note that using `-c 'set noloadplugins'` doesn't work, because the commands from the command line have not been executed yet. You can use `--cmd 'set noloadplugins'` or `--cmd 'set loadplugins'` --cmd.
    - Packages are loaded. These are plugins, as above, but found in the "start" directory of each entry in 'packpath'. Every plugin directory found is added in 'runtimepath' and then the plugins are sourced. See packages.
    - The plugins scripts are loaded, as above, but now only the directories ending in "after" are used. Note that 'runtimepath' will have changed if packages have been found, but that should not add a directory ending in "after".
13. Set 'shellpipe' and 'shellredir', according to the value of the 'shell' option, unless they were already set. Nvim will figure out the values of 'shellpipe' and 'shellredir' for you, unless you have set them yourself.
14. Set 'updatecount' to zero, if -n was given.
15. Set binary options if -b was given.
16. Read the shada-file.
17. Read the quickfix file if -q was given, or exit on failure.
18. Open all windows.
    - When -o was given, windows will be opened (but not displayed yet).
    - When -p was given, tabpages will be created (but not displayed yet).
    - When switching screens, it happens now. Redrawing starts.
    - If -q was given, the first error is jumped to.
    - Buffers for all windows will be loaded, without triggering BufAdd.
19. Execute startup commands.
    - If -t was given, the tag is jumped to.
    - Commands given with -c and +cmd are executed.

- The vim_starting flag is reset, `has("vim_starting")` will now return zero.
- The v:vim_did_enter variable is set to 1.
- The VimEnter autocommands are executed.

Saving the current state of Vim to a file

Whenever you have changed values of options or when you have created a mapping, then you may want to save them in a vimrc file for later use. See save-settings about saving the current state of settings to a file.

Avoiding trojan horses

trojan-horse

While reading the "vimrc" or the "exrc" file in the current directory, some commands can be disabled for security reasons by setting the 'secure' option. This is always done when executing the command from a tags file. Otherwise, it would be possible that you accidentally use a vimrc or tags file that somebody else created and contains nasty commands. The disabled commands are the ones that start a shell, the ones that write to a file, and ":autocmd". The ":map" commands are echoed, so you can see which keys are being mapped.

If you want Vim to execute all commands in a local vimrc file, you can reset the 'secure' option in the EXINIT or VIMINIT environment variable or in the global exrc or vimrc file. This is not possible in vimrc or exrc in the current directory, for obvious reasons.

On Unix systems, this only happens if you are not the owner of the vimrc file. **Warning:** If you unpack an archive that contains a vimrc or exrc file, it will be owned by you. You won't have the security protection. Check the vimrc file before you start Vim in that directory, or reset the 'exrc' option. Some Unix systems allow a user to do "chown" on a file. This makes it possible for another user to create a nasty vimrc and make you the owner. Be careful!

When using tag search commands, executing the search command (the last part of the line in the tags file) is always done in secure mode. This works just like executing a command from a vimrc in the current directory.

If Vim startup is slow

slow-start

If Vim takes a long time to start up, use the --startuptime argument to find out what happens.

If you have 'shada' enabled, the loading of the ShaDa file may take a while. You can find out if this is the problem by disabling ShaDa for a moment (use the Vim argument "-i NONE", -i). Try reducing the number of lines stored in a register with ":set shada='20,<50,s10". shada-file.

Troubleshooting broken configurations

bisect

The extreme flexibility of editors like Vim and Emacs means that any plugin or setting can affect the entire editor in ways that are not initially obvious.

To find the cause of a problem in your config, you must "bisect" it:

1. Remove or disable half of your config.
2. Restart Nvim (:restart).
3. If the problem still occurs, goto 1.
4. If the problem is gone, restore half of the removed lines.
5. Continue narrowing your config in this way, until you find the setting or plugin causing the issue.

Intro message

:intro

When Vim starts without a file name, an introductory message is displayed. It is removed as soon as the display is redrawn. To see the message again, use the ":intro" command. To avoid the intro message on startup, add the "I" flag to 'shortmess'.

$VIM and $VIMRUNTIME

$VIM

The environment variable "$VIM" is used to locate various user files for Nvim, such as the user config. This depends on the system, see startup.

Nvim will try to get the value for $VIM in this order:

1. Environment variable $VIM, if it is set.
2. Path derived from the 'helpfile' option, unless it contains some environment variable too (default is "$VIMRUNTIME/doc/help.txt"). File name ("help.txt", etc.) is removed. Trailing directory names are removed, in this order: "doc", "runtime".
3. Path derived from the location of the `nvim` executable.
4. Compile-time defined installation directory (see output of ":version").

After doing this once, Nvim sets the $VIM environment variable.

$VIMRUNTIME

The environment variable "$VIMRUNTIME" is used to locate various support files, such as the documentation and syntax-highlighting files. For example, the main help file is normally "$VIMRUNTIME/doc/help.txt".

Nvim will try to get the value for $VIMRUNTIME in this order:

1. Environment variable $VIMRUNTIME, if it is set.
2. Directory path "$VIM/runtime", if it exists.
3. Value of $VIM environment variable. This is for backwards compatibility with older Vim versions.
4. If "../share/nvim/runtime" exists relative to v:progpath, it is used.
5. Path derived from the 'helpfile' option (if it doesn't contain '$') with "doc/help.txt" removed from the end.

After doing this once, Nvim sets the $VIMRUNTIME environment variable.

In case you need the value of $VIMRUNTIME in a shell (e.g., for a script that greps in the help files) you might be able to use this:

```
VIMRUNTIME="$(nvim --clean --headless --cmd 'echo $VIMRUNTIME|q')"
```

Suspending **suspend**

CTRL-Z v_CTRL-Z CTRL-Z Suspend Nvim, like ":stop". Works in Normal and in Visual mode. In Insert and Command-line mode, the CTRL-Z is inserted as a normal character. In Visual mode Nvim goes back to Normal mode before suspending.

:sus[pend][!] or :sus :suspend :st :stop :st[op][!] Suspend Nvim using OS "job control"; it will continue if you make it the foreground job again. Triggers VimSuspend before suspending and VimResume when resumed.

If "!" is not given and 'autowrite' is set, every buffer with changes and a file name is written out. If "!" is given or 'autowrite' is not set, changed buffers are not written, don't forget to bring Nvim back to the foreground later!

In the GUI, suspending is implementation-defined.

Exiting **exiting**

There are several ways to exit Vim:
- Close the last window with `:quit`. Only when there are no changes.
- Close the last window with `:quit!`. Also when there are changes.
- Close all windows with `:qall`. Only when there are no changes.
- Close all windows with `:qall!`. Also when there are changes.
- Use `:cquit`. Also when there are changes.

When using `:cquit` or when there was an error message Vim exits with exit code 1. Errors can be avoided by using `:silent!` or with `:catch`.

Saving settings **save-settings**

Mostly you will edit your vimrc files manually. This gives you the greatest flexibility. There are a few commands to generate a vimrc file automatically. You can use these files as they are, or copy/paste lines to include in another vimrc file.

:mk :mkexrc :mk[exrc] [file] Write current key mappings and changed options to [file] (default ".exrc" in the current directory), unless it already exists.

:mk[exrc]! [file] Always write current key mappings and changed options to [file] (default ".exrc" in the current directory).

:mkv :mkvi :mkvimrc :mkv[imrc][!] [file] Like ":mkexrc", but the default is ".nvimrc" in the current directory. The ":version" command is also written to the file.

These commands will write ":map" and ":set" commands to a file, in such a way that when these commands are executed, the current key mappings and options will be set to the same values. The options 'columns', 'endofline', 'fileformat', 'lines', 'modified', and 'scroll' are not included, because these are terminal or file dependent. Note that the options 'binary', 'paste' and 'readonly' are included, this might not always be what you want.

When special keys are used in mappings, the 'cpoptions' option will be temporarily set to its Vim default, to avoid the mappings to be misinterpreted. This makes the file incompatible with Vi, but makes sure it can be used with different terminals.

Only global mappings are stored, not mappings local to a buffer.

A common method is to use a default config file, make some modifications with ":map" and ":set" commands and write the modified file. First read the default vimrc in with a command like ":source ~piet/.vimrc.Cprogs", change the settings and then save them in the current directory with ":mkvimrc!". If you want to make this file your default config, move it to $XDG_CONFIG_HOME/nvim. You could also use autocommands autocommand and/or modelines modeline.

vimrc-option-example

If you only want to add a single option setting to your vimrc, you can use these steps:
1. Edit your vimrc file with Vim.
2. Play with the option until it's right. E.g., try out different values for 'guifont'.
3. Append a line to set the value of the option, using the expression register '=' to enter the value. E.g., for the 'guifont' option:

```
o:set guifont=<C-R>=&guifont<CR><Esc>
```

[<C-R> is a CTRL-R, <CR> is a return, <Esc> is the escape key] You need to escape special characters, esp. spaces.

Views and Sessions **views-sessions**

This is introduced in sections 21.4 and 21.5 of the user manual.

View view-file A View is a collection of settings that apply to one window. You can save a View and when you restore it later, the text is displayed in the same way. The options and mappings in this window will also be restored, so that you can continue editing like when the View was saved.

Session session-file A Session keeps the Views for all windows, plus the global settings. You can save a Session and when you restore it later the window layout looks the same. You can use a Session to quickly switch between different projects, automatically loading the files you were last working on in that project.

Views and Sessions are a nice addition to ShaDa files, which are used to remember information for all Views and Sessions together shada-file.

You can quickly start editing with a previously saved View or Session with the -S argument:

```
vim -S Session.vim
```

:mks :mksession :mks[ession][!] [file] Write a Vim script that restores the current editing session. When [!] is included, an existing file is overwritten. When [file] is omitted, "Session.vim" is used.

The output of ":mksession" is like ":mkvimrc", but additional commands are added to the file. Which ones depends on the 'sessionoptions' option. The resulting file, when executed with a ":source" command:
1. Restores global mappings and options, if 'sessionoptions' contains "options". Lua functions, and script-local mappings, will not be written.

2. Restores global variables that start with an uppercase letter and contain at least one lowercase letter, if 'sessionoptions' contains "globals".
3. Closes all windows in the current tabpage, except the current one; closes all tabpages except the current one (this results in currently loaded buffers to be unloaded, some may become hidden if 'hidden' is set or otherwise specified); wipes out the current buffer, if it is empty and unnamed.
4. Restores the current directory, if 'sessionoptions' contains "curdir", or sets the current directory to where the Session file is, if 'sessionoptions' contains "sesdir".
5. Restores GUI Vim window position, if 'sessionoptions' contains "winpos".
6. Restores screen size, if 'sessionoptions' contains "resize".
7. Reloads the buffer list, with the last cursor positions. If 'sessionoptions' contains "buffers" then all buffers are restored, including hidden and unloaded buffers. Otherwise, only buffers in windows are restored.
8. Restores all windows with the same layout. If 'sessionoptions' contains "help", help windows are restored. If 'sessionoptions' contains "blank", windows editing a buffer without a name will be restored. If 'sessionoptions' contains "winsize" and no (help/blank) windows were left out, the window sizes are restored (relative to the screen size). Otherwise, the windows are just given sensible sizes.
9. Restores the Views for all the windows, as with :mkview. But 'sessionoptions' is used instead of 'viewoptions'.
10. If a file exists with the same name as the Session file, but ending in "x.vim" (for eXtra), executes that as well. You can use `*x.vim` files to specify additional settings and actions associated with a given Session, such as creating menu items in the GUI version.

After restoring the Session, the full filename of your current Session is available in the internal variable v:this_session. An example mapping:

```
:nmap <F2> :wa<Bar>exe "mksession! " .. v:this_session<CR>:so ~/sessions/
```

This saves the current Session, and starts off the command to load another.

A session includes all tabpages, unless "tabpages" was removed from 'sessionoptions'. tabpage

The SessionLoadPre autocmd event is triggered before a session file is loaded/sourced and SessionLoadPost autocmd event is triggered after. While the session file is loading, `g:SessionLoad` is set to 1. Plugins can use this to postpone some work until the SessionLoad-variable SessionLoadPost event is triggered.

:mkvie :mkview :mkvie[w][!] [file] Write a Vim script that restores the contents of the current window. When [!] is included, an existing file is overwritten. When [file] is omitted or is a number from 1 to 9, a name is generated and 'viewdir' prepended. When the last path part of 'viewdir' does not exist, this directory is created. E.g., when 'viewdir' is "$VIM/vimfiles/view" then "view" is created in "$VIM/vimfiles". An existing file is always overwritten then. Use :loadview to load this view again. When [file] is the name of a file ('viewdir' is not used), a command to edit the file is added to the generated file.

The output of ":mkview" contains these items:
1. The argument list used in the window. When the global argument list is used, it is reset to the global list. The index in the argument list is also restored.
2. The file being edited in the window. If there is no file, the window is made empty.
3. Restore mappings, abbreviations and options local to the window, if 'viewoptions' contains "options" or "localoptions". Only option values that are local to the current buffer and the current window are restored. When storing the view as part of a session and "options" is in 'sessionoptions', global values for local options will be stored too. Lua functions are not restored.
4. Restore folds when using manual folding and 'viewoptions' contains "folds". Restore manually opened and closed folds.
5. The scroll position and the cursor position in the file. Doesn't work very well when there are closed folds.
6. The local current directory, if it is different from the global current directory and 'viewoptions' contains "curdir".

Note that Views and Sessions are not perfect:
- They don't restore everything. For example, defined functions, autocommands and ":syntax on" are not included. Things like register contents and command line history are in ShaDa, not in Sessions or Views.
- Global option values are only set when they differ from the default value. When the current value is not the default value, loading a Session will not set it back to the default value. Local options will be set back to the default value though.
- Existing mappings will be overwritten without warning. An existing mapping may cause an error for ambiguity.
- When storing manual folds and when storing manually opened/closed folds, changes in the file between saving and loading the view will mess it up.
- The Vim script is not very efficient. But still faster than typing the commands yourself!

:lo :loadview :lo[adview] [nr] Load the view for the current file. When [nr] is omitted, the view stored with ":mkview" is loaded. When [nr] is specified, the view stored with ":mkview [nr]" is loaded.

The combination of ":mkview" and ":loadview" can be used to store up to ten different views of a file. These are remembered in the directory specified with the 'viewdir' option. The views are stored using the file name. If a file is renamed or accessed through a (symbolic) link, the view will not be found.

You might want to clean up your 'viewdir' directory now and then.

To automatically save and restore views for `*.c` files:

```
au BufWinLeave *.c mkview
au BufWinEnter *.c silent! loadview
```

Shada ("shared data") file

shada shada-file

If you exit Vim and later start it again, you would normally lose a lot of information. The ShaDa file can be used to remember that information, which enables you to continue where you left off. Its name is the abbreviation of SHAred DAta because it is used for sharing data between Nvim sessions.

This is introduced in section 21.3 of the user manual.

The ShaDa file is used to store:
- The command line history.
- The search string history.
- The input-line history.
- Contents of non-empty registers.

- Marks for several files.
- File marks, pointing to locations in files.
- Last search/substitute pattern (for 'n' and '&').
- The buffer list.
- Global variables.

You could also use a Session file. The difference is that the ShaDa file does not depend on what you are working on. There normally is only one ShaDa file. Session files are used to save the state of a specific editing Session. You could have several Session files, one for each project you are working on. ShaDa and Session files together can be used to effectively enter Vim and directly start working in your desired setup. session-file

shada-read

When Vim is started and the 'shada' option is non-empty, the contents of the ShaDa file are read and the info can be used in the appropriate places. The v:oldfiles variable is filled. The marks are not read in at startup (but file marks are). See initialization for how to set the 'shada' option upon startup.

shada-write

When Vim exits and 'shada' is non-empty, the info is stored in the ShaDa file (it's actually merged with the existing one, if one exists shada-merging). The 'shada' option is a string containing information about what info should be stored, and contains limits on how much should be stored (see 'shada').

Notes for Unix:
- The file protection for the ShaDa file will be set to prevent other users from being able to read it, because it may contain any text or commands that you have worked with.
- If you want to share the ShaDa file with other users (e.g. when you "su" to another user), you can make the file writable for the group or everybody. Vim will preserve this when writing new ShaDa files. Be careful, don't allow just anybody to read and write your ShaDa file!
- Vim will not overwrite a ShaDa file that is not writable by the current "real" user. This helps for when you did "su" to become root, but your $HOME is still set to a normal user's home directory. Otherwise, Vim would create a ShaDa file owned by root that nobody else can read.
- The ShaDa file cannot be a symbolic link. This is to avoid security issues.

Marks are stored for each file separately. When a file is read and 'shada' is non-empty, the marks for that file are read from the ShaDa file. **NOTE:** The marks are only written when exiting Vim, which is fine because marks are remembered for all the files you have opened in the current editing session, unless ":bdel" is used. If you want to save the marks for a file that you are about to abandon with ":bdel", use ":wsh". The '[' and ']' marks are not stored, but the '"' mark is. The '"' mark is very useful for jumping to the cursor position when the file was last exited. No marks are saved for files that start with any string given with the "r" flag in 'shada'. This can be used to avoid saving marks for files on removable media (for MS-Windows you would use "ra:,rb:"). The v:oldfiles variable is filled with the file names that the ShaDa file has marks for.

shada-file-marks

Uppercase marks ('A to 'Z) are stored when writing the ShaDa file. The numbered marks ('0 to '9) are a bit special. When the ShaDa file is written (when exiting or with the :wshada command), '0 is set to the current cursor position and file. The old '0 is moved to '1, '1 to '2, etc. This resembles what happens with the "1 to "9 delete registers. If the current cursor position is already present in '0 to '9, it is moved to '0, to avoid having the same position twice. The result is that with "'0", you can jump back to the file and line where you exited Vim. To do that right away, try using this command:

```
vim -c "normal '0"
```

In a C shell descendant, you could make an alias for it:

```
alias lvim vim -c '"'normal "'"0'"'
```

For a Bash-like shell:

```
alias lvim='vim -c "normal '\''0"'
```

Use the "r" flag in 'shada' to specify for which files no marks should be remembered.

MERGING

shada-merging

When writing ShaDa files with :wshada without bang or at regular exit information in the existing ShaDa file is merged with information from current Nvim instance. For this purpose ShaDa files store timestamps associated with ShaDa entries. Specifically the following is being done:

1. History lines are merged, ordered by timestamp. Maximum amount of items in ShaDa file is defined by 'shada' option (shada-/, shada-:, shada-@, etc: one suboption for each character that represents history name (:history)).
2. Local marks and changes for files that were not opened by Nvim are copied to new ShaDa file. Marks for files that were opened by Nvim are merged, changes to files opened by Nvim are ignored. shada-'
3. Jump list is merged: jumps are ordered by timestamp, identical jumps (identical position AND timestamp) are squashed.
4. Search patterns and substitute strings are not merged: search pattern or substitute string which has greatest timestamp will be the only one copied to ShaDa file.
5. For each register entity with greatest timestamp is the only saved. shada-<
6. All saved variables are saved from current Nvim instance. Additionally existing variable values are copied, meaning that the only way to remove variable from a ShaDa file is either removing it by hand or disabling writing variables completely. shada-!
7. For each global mark entity with greatest timestamp is the only saved.
8. Buffer list and header are the only entries which are not merged in any fashion: the only header and buffer list present are the ones from the Nvim instance which was last writing the file. shada-%

COMPATIBILITY

shada-compatibility

ShaDa files are forward and backward compatible. This means that

1. Entries which have unknown type (i.e. that hold unidentified data) are ignored when reading and blindly copied when writing.
2. Register entries with unknown register name are ignored when reading and blindly copied when writing. Limitation: only registers that use name with code in interval [1, 255] are supported. registers

3. Register entries with unknown register type are ignored when reading and merged as usual when writing. getregtype()
4. Local and global mark entries with unknown mark names are ignored when reading. When writing global mark entries are blindly copied and local mark entries are also blindly copied, but only if file they are attached to fits in the shada-' limit. Unknown local mark entry's timestamp is also taken into account when calculating which files exactly should fit into this limit. Limitation: only marks that use name with code in interval [1, 255] are supported. mark-motions
5. History entries with unknown history type are ignored when reading and blindly copied when writing. Limitation: there can be only up to 256 history types. history
6. Unknown keys found in register, local mark, global mark, change, jump and search pattern entries are saved internally and dumped when writing. Entries created during Nvim session never have such additions.
7. Additional elements found in replacement string and history entries are saved internally and dumped. Entries created during Nvim session never have such additions.
8. Additional elements found in variable entries are simply ignored when reading. When writing new variables they will be preserved during merging, but that's all. Variable values dumped from current Nvim session never have additional elements, even if variables themselves were obtained by reading ShaDa files.

"Blindly" here means that there will be no attempts to somehow merge them, even if other entries (with known name/type/etc) are merged. shada-merging

SHADA FILE NAME **shada-file-name**

- Default name of the shada file is: Unix: "$XDG_STATE_HOME/nvim/shada/main.shada" Windows: "$XDG_STATE_HOME/nvim-data/shada/main.shada" See also base-directories.
- To choose a different file name you can use:
  - The "n" flag in the 'shada' option.
  - The -i startup argument. "NONE" means no shada file is ever read or written. Also not for the commands below!
  - The 'shadafile' option. The value from the "-i" argument (if any) is stored in the 'shadafile' option.
- For the commands below, another file name can be given, overriding the default and the name given with 'shada' or "-i" (unless it's NONE).

MANUALLY READING AND WRITING **shada-read-write**

Two commands can be used to read and write the ShaDa file manually. This can be used to exchange registers between two running Vim programs: First type ":wsh" in one and then ":rsh" in the other. Note that if the register already contained something, then ":rsh!" would be required. Also note, however, that this means everything will be overwritten with information from the first Vim, including the command line history, etc.

The ShaDa file itself can be edited by hand too, although we suggest you start with an existing one to get the format right. You need to understand MessagePack (or, more likely, find software that is able to use it) format to do this. This can be useful in order to create a second file, say "~/.my.shada", which could contain certain settings that you always want when you first start Nvim. For example, you can preload registers with particular data, or put certain commands in the command line history. A line in your config file like

```
:rshada! ~/.my.shada
```

can be used to load this information. You could even have different ShaDa files for different types of files (e.g., C code) and load them based on the file name, using the ":autocmd" command (see :autocmd). More information on ShaDa file format is contained in shada-format section.

E136 E929 shada-error-handling Some errors make Nvim leave temporary file named `{basename}.tmp.X` (X is any free letter from a to z) while normally it will create this file, write to it and then rename `{basename}.tmp.X` to `{basename}`. Such errors include:

- Errors which make Nvim think that the file being read is not a ShaDa file at all: non-ShaDa files are not overwritten for safety reasons to avoid accidentally destroying an unrelated file. This could happen e.g. when typing "nvim -i file" in place of "nvim -R file" (yes, somebody did that at least with Vim). Such errors are listed at shada-critical-contents-errors.
- If writing to the temporary file failed: e.g. because of the insufficient space left.
- If renaming file failed: e.g. because of insufficient permissions.
- If target ShaDa file has different from the Nvim instance's owners (user and group) and changing them failed. Unix-specific, applies only when Nvim was launched from root.

Do not forget to remove the temporary file or replace the target file with temporary one after getting one of the above errors or all attempts to create a ShaDa file may fail with E929. If you got one of them when using :wshada (and not when exiting Nvim: i.e. when you have Nvim session running) you have additional options:

- First thing which you should consider if you got any error, except failure to write to the temporary file: remove existing file and replace it with the temporary file. Do it even if you have running Nvim instance.
- Fix the permissions and/or file ownership, free some space and attempt to write again. Do not remove the existing file.
- Use :wshada with bang. Does not help in case of permission error. If target file was actually the ShaDa file some information may be lost in this case. To make the matters slightly better use :rshada prior to writing, but this still will loose buffer-local marks and change list entries for any file which is not opened in the current Nvim instance.
- Remove the target file from shell and use :wshada. Consequences are not different from using :wshada with bang, but "rm -f" works in some cases when you don't have write permissions.

:rsh :rshada E886 :rsh[ada][!] [file] Read from ShaDa file [file] (default: see above). If [!] is given, then any information that is already set (registers, marks, v:oldfiles, etc.) will be overwritten.

:wsh :wshada E137 E138 :wsh[ada][!] [file] Write to ShaDa file [file] (default: see above). The information in the file is first read in to make a merge between old and new info. When [!] is used, the old information is not read first, only the internal info is written (also disables safety checks described in shada-error-handling). If 'shada' is empty, marks for up to 100 files will be written. When you get error "E929: All .tmp.X files exist, cannot write ShaDa file!", check that no old temp files were left behind (e.g. ~/.local/state/nvim/shada/main.shada.tmp*).

Note: Executing :wshada will reset all 'quote marks.

:o :ol :oldfiles :o[ldfiles] List the files that have marks stored in the ShaDa file. This list is read on startup and only changes afterwards with `:rshada!`. Also see v:oldfiles. The number can be used with c_#<. The output can be filtered with :filter, e.g.:

```
filter /\.vim/ oldfiles
```

The filtering happens on the file name.

:bro[wse] o[ldfiles][!] List file names as with :oldfiles, and then prompt for a number. When the number is valid that file from the list is edited.

Use [!] to abandon a modified buffer. abandon

SHADA FILE FORMAT shada-format

ShaDa files are concats of MessagePack entries. Each entry is a concat of exactly four MessagePack objects:

1. First goes type of the entry. Object type must be an unsigned integer. Object type must not be equal to zero.
2. Second goes entry timestamp. It must also be an unsigned integer.
3. Third goes the length of the fourth entry. Unsigned integer as well, used for fast skipping without parsing.
4. Fourth is actual entry data. All currently used ShaDa entries use containers to hold data: either map or array. All string values in those containers are either binary (applies to filenames) or UTF-8, yet parser needs to expect that invalid bytes may be present in a UTF-8 string.

Exact format depends on the entry type:

Entry type (name) Entry data

- 1 (Header) Map containing data that describes the generator instance that wrote this ShaDa file. It is ignored when reading ShaDa files. Contains the following data: Key Data

```
generator  Binary, software used to generate ShaDa
           file. Is equal to "nvim" when ShaDa file was
           written by Nvim.
version    Binary, generator version.
encoding   Binary, effective 'encoding' value.
max_kbyte  Integer, effective |shada-s| limit value.
pid        Integer, instance process ID.
*          It is allowed to have any number of
           additional keys with any data.
```

- 2 (SearchPattern) Map containing data describing last used search or substitute pattern. Normally ShaDa file contains two such entries: one with "ss" key set to true (describes substitute pattern, see :substitute), and one set to false (describes search pattern, see search-commands). "su" key should be true on one of the entries. If key value is equal to default then it is normally not present. Keys: Key Type Default Description

```
sm   Boolean  true     Effective 'magic' value.
sc   Boolean  false    Effective 'smartcase' value.
sl   Boolean  true     True if search pattern comes
                       with a line offset.  See
                       |search-offset|.
se   Boolean  false    True if |search-offset|
                       requested to place cursor at
                       (relative to) the end of the
                       pattern.
so   Integer  0        Offset value. |search-offset|
su   Boolean  false    True if current entry was the
                       last used search pattern.
ss   Boolean  false    True if current entry describes
                       |:substitute| pattern.
sh   Boolean  false    True if |v:hlsearch| is on.
                       With |shada-h| or 'nohlsearch'
                       this key is always false.
sp   Binary   N/A      Actual pattern.  Required.
sb   Boolean  false    True if search direction is
                       backward.
*    any      none     Other keys are allowed for
                       compatibility reasons, see
                       |shada-compatibility|.
```

- 3 (SubString) Array containing last :substitute replacement string. Contains single entry: binary, replacement string used. More entries are allowed for compatibility reasons, see shada-compatibility.
- 4 (HistoryEntry) Array containing one entry from history. Should have two or three entries. First one is history type (unsigned integer), second is history line (binary), third is the separator character (unsigned integer, must be in interval [0, 255]). Third item is only valid for search history. Possible history types are listed in hist-names, here are the corresponding numbers: 0 - cmd, 1 - search, 2 - expr, 3 - input, 4 - debug.
- 5 (Register) Map describing one register (registers). If key value is equal to default then it is normally not present. Keys: Key Type Def Description

```
rt   UInteger         0     Register type:
                           No  Description ~
                           0   |charwise-register|
                           1   |linewise-register|
                           2   |blockwise-register|
rw   UInteger         0     Register width. Only valid
                           for |blockwise-register|s.
rc   Array of binary  N/A   Register contents.  Each
                           entry in the array
                           represents its own line.
                           NUL characters inside the
                           line should be represented
                           as NL according to
                           |NL-used-for-Nul|.
ru   Boolean          false Unnamed register. Whether
                           the unnamed register had
                           pointed to this register.
n    UInteger         N/A   Register name: character
                           code in range [1, 255].
                           Example: |quote0| register
                           has name 48 (ASCII code for
                           zero character).
*    any              none  Other keys are allowed
                           for compatibility reasons,
                           see |shada-compatibility|.
```

- 6 (Variable) Array containing two items: variable name (binary) and variable value (any object). Values are converted using the same code msgpackparse() uses when reading, msgpackdump() when writing, so there may appear msgpack-special-dicts. If there are more then two entries then the rest are ignored (shada-compatibility).
- 7 (GlobalMark)
- 8 (Jump)
- 10 (LocalMark)
- 11 (Change) Map containing some position description: Entry Position

```
GlobalMark Global mark position. |'A|
LocalMark  Local mark position. |'a|
Jump       One position from the |jumplist|.
Change     One position from the |changelist|.

Data contained in the map:
Key  Type      Default  Description ~
l    UInteger  1        Position line number.  Must be
                        greater then zero.
c    UInteger  0        Position column number.
n    UInteger  34 ('"') Mark name.  Only valid for
                        GlobalMark and LocalMark
                        entries.
f    Binary    N/A      File name.  Required.
*    any       none     Other keys are allowed for
                        compatibility reasons, see
                        |shada-compatibility|.
```

- 9 (BufferList) Array containing maps. Each map in the array represents one buffer. Possible keys: Key Type Default Description

```
l    UInteger  1        Position line number.  Must be
                        greater then zero.
c    UInteger  0        Position column number.
f    Binary    N/A      File name.  Required.
*    any       none     Other keys are allowed for
                        compatibility reasons, see
                        |shada-compatibility|.
```

- * (Unknown) Any other entry type is allowed for compatibility reasons, see shada-compatibility.

E574 E575 E576 Errors in ShaDa file may have two types:

1. E575 for “logical” errors.
2. E576 for “critical” errors.

When writing, critical errors trigger behaviour described in shada-error-handling. When reading, critical errors cause the rest of the file to be skipped.

Critical errors include: shada-critical-contents-errors

- Any of first three MessagePack objects being not an unsigned integer.
- Third object requesting amount of bytes greater then bytes left in the ShaDa file.
- Entry with zero type. I.e. first object being equal to zero.
- MessagePack parser failing to parse the entry data.
- MessagePack parser consuming less or requesting greater bytes then described in the third object for parsing fourth object. I.e. when fourth object either contains more then one MessagePack object or it does not contain complete MessagePack object.

Standard Paths standard-path

Nvim stores configuration, data, and logs in standard locations. Plugins are strongly encouraged to follow this pattern also. Use stdpath() to get the paths.

base-directories xdg The "base" (root) directories conform to the XDG Base Directory Specification.
https://specifications.freedesktop.org/basedir/latest/

The $XDG_CONFIG_HOME, $XDG_DATA_HOME, $XDG_RUNTIME_DIR, $XDG_STATE_HOME, $XDG_CACHE_HOME, $XDG_CONFIG_DIRS and $XDG_DATA_DIRS environment variables are used if defined, else default values (listed below) are used.

Note: In the help these defaults are used as placeholders, e.g. "~/.config" is understood as "$XDG_CONFIG_HOME or ~/.config".

CONFIG DIRECTORY (DEFAULT)
$XDG_CONFIG_HOME Nvim: stdpath("config")

```
Unix:         ~/.config                  ~/.config/nvim
Windows:      ~/AppData/Local            ~/AppData/Local/nvim
```

DATA DIRECTORY (DEFAULT)
$XDG_DATA_HOME Nvim: stdpath("data")

```
Unix:         ~/.local/share             ~/.local/share/nvim
Windows:      ~/AppData/Local            ~/AppData/Local/nvim-data
```

RUN DIRECTORY (DEFAULT)
$XDG_RUNTIME_DIR Nvim: stdpath("run")

```
Unix:         /tmp/nvim.user/xxx         /tmp/nvim.user/xxx
Windows:      $TMP/nvim.user/xxx         $TMP/nvim.user/xxx
```

STATE DIRECTORY (DEFAULT)
$XDG_STATE_HOME Nvim: stdpath("state")

```
Unix:         ~/.local/state             ~/.local/state/nvim
Windows:      ~/AppData/Local            ~/AppData/Local/nvim-data
```

CACHE DIRECTORY (DEFAULT)
$XDG_CACHE_HOME Nvim: stdpath("cache")

```
Unix:         ~/.cache                   ~/.cache/nvim
Windows:      ~/AppData/Local/Temp       ~/AppData/Local/Temp/nvim-data
```

LOG DIRECTORY (DEFAULT)
$XDG_STATE_HOME/.../logs Nvim: stdpath("log")

```
Unix:         Not applicable             ~/.local/state/nvim/logs
Windows:      Not applicable             ~/AppData/Local/nvim-data/logs
```

LOG FILE (DEFAULT)
$NVIM_LOG_FILE Nvim: stdpath("log")/nvim.log

```
Unix:         ~/.local/state/nvim        ~/.local/state/nvim/logs/nvim.log
Windows:      ~/AppData/Local/nvim-data  ~/AppData/Local/nvim-data/logs/nvim.log
```

ADDITIONAL CONFIGS DIRECTORY (DEFAULT)
$XDG_CONFIG_DIRS Nvim: stdpath("config_dirs")

```
Unix:         /etc/xdg/                  /etc/xdg/nvim
Windows:      Not applicable             Not applicable
```

ADDITIONAL DATA DIRECTORY (DEFAULT)
$XDG_DATA_DIRS Nvim: stdpath("data_dirs")

```
Unix:         /usr/local/share           /usr/local/share/nvim
              /usr/share                 /usr/share/nvim
Windows:      Not applicable             Not applicable
```

NVIM_APPNAME **$NVIM_APPNAME**

The standard directories can be further configured by the $NVIM_APPNAME environment variable. This variable controls the sub-directory that Nvim will read from (and auto-create) in each of the base directories. For example, setting $NVIM_APPNAME to "foo" before starting will cause Nvim to look for configuration files in $XDG_CONFIG_HOME/foo instead of $XDG_CONFIG_HOME/nvim. $NVIM_APPNAME must be a name, such as "foo", or a relative path, such as "foo/bar".

Note: In the help wherever $XDG_CONFIG_…/nvim is mentioned it is understood as $XDG_CONFIG_…/$NVIM_APPNAME.

state-isolation

One use-case for $NVIM_APPNAME is to "isolate" Nvim applications. Alternatively, for true isolation, on Linux you can use cgroups namespaces:

```
systemd-run --user -qt -p PrivateUsers=yes -p BindPaths=/home/user/profile_xy:/home/user/.config/nvim nvim
```

stateless

To run Nvim without creating any directories or data files:

```
NVIM_LOG_FILE=/dev/null nvim -n -i NONE
```

LOG FILE **log** **$NVIM_LOG_FILE** **E5430**

Besides 'debug' and 'verbose', Nvim keeps a general log file for internal debugging, plugins and RPC clients. The log file can be viewed with:

```
:log nvim
```

Default location is stdpath("log")/nvim.log ($XDG_STATE_HOME/nvim/logs/nvim.log) unless that path is inaccessible or $NVIM_LOG_FILE was set before startup.

See log-files for details about other log files that can be created by Nvim during runtime or by plugins.

Supported platforms

supported-platforms

System	Tier	Versions	Tested versions
Linux (x86_64)	1	>= 2.6.32, glibc >= 2.12	Ubuntu 24.04
Linux (arm64)	1	>= 2.6.32, glibc >= 2.12	Ubuntu 24.04
macOS (x86_64)	1	>= 11	macOS 15
macOS (arm64)	1	>= 11	macOS 26
Windows 64-bit	1	>= Windows 10 Version 2004	Windows Server 2025
FreeBSD	2	>= 10	
OpenBSD	2	>= 7	
MinGW	2	MinGW-w64	
Windows 64-bit	3	< Windows 10 Version 2004	

Note: Windows 10 "Version 2004" or later is required for :terminal. To check your Windows version, run the "winver" command and look for "Version xxxx" (NOT "OS Build").

Note: On Windows "Server" you may need to install vcruntime140.dll: https://learn.microsoft.com/en-us/cpp/windows/latest-supported-vc-redist?view=msvc-170

Support types

- Tier 1: Officially supported and tested with CI. Any contributed patch MUST NOT break support for such platforms.
- Tier 2: Officially supported, but not necessarily tested with CI. Support for these platforms are maintained by best effort, without being a top priority.
- Tier 3: Not tested and no guarantees, and not all features may work.

Adding support for a new platform

IMPORTANT: Before attempting to add support for a new platform please open an issue about it for discussion.

Common

Some common notes when adding support for new platforms:

CMake is the only supported build system. Nvim must be buildable on the platform with CMake.

All functionality related to the new platform must be implemented in its own file inside src/nvim/os unless it's already done in a common file, in which case adding an #ifdef is fine.

Syntax highlighting syntax-highlighting coloring

Syntax highlighting enables Vim to show parts of the text in another font or color. Those parts can be specific keywords or text matching a pattern. Vim doesn't parse the whole file (to keep it fast), so the highlighting has its limitations. Lexical highlighting might be a better name, but since everybody calls it syntax highlighting we'll stick with that.

Vim supports syntax highlighting on all terminals. But since most ordinary terminals have very limited highlighting possibilities, it works best in the GUI version, gvim.

In the User Manual:
usr_06.txt introduces syntax highlighting.
usr_44.txt introduces writing a syntax file.

1. Quick start :syn-qstart

:syn-enable :syntax-enable :syn-on :syntax-on
Syntax highlighting is enabled by default. If you need to enable it again after it was disabled (see below), use:

```
:syntax enable
```

Alternatively:

```
:syntax on
```

What this command actually does is to execute the command

```
:source $VIMRUNTIME/syntax/syntax.vim
```

If the VIM environment variable is not set, Vim will try to find the path in another way (see $VIMRUNTIME). Usually this works just fine. If it doesn't, try setting the VIM environment variable to the directory where the Vim stuff is located. For example, if your syntax files are in the "/usr/vim/vim82/syntax" directory, set $VIMRUNTIME to "/usr/vim/vim82". You must do this in the shell, before starting Vim. This command also sources the menu.vim script when the GUI is running or will start soon.

:hi-normal :highlight-normal
If you are running in the GUI, you can get white text on a black background with:

```
:highlight Normal guibg=Black guifg=White
```

For a color terminal see :hi-normal-cterm.

NOTE: The syntax files on MS-Windows have lines that end in <CR><NL>. The files for Unix end in <NL>. This means you should use the right type of file for your system. Although on MS-Windows the right format is automatically selected if the 'fileformats' option is not empty.

NOTE: When using reverse video ("gvim -fg white -bg black"), the default value of 'background' will not be set until the GUI window is opened, which is after reading the gvimrc. This will cause the wrong default highlighting to be used. To set the default value of 'background' before switching on highlighting, include the ":gui" command in the gvimrc:

```
:gui            " open window and set default for 'background'
:syntax on      " start highlighting, use 'background' to set colors
```

NOTE: Using ":gui" in the gvimrc means that "gvim -f" won't start in the foreground! Use ":gui -f" then.

g:syntax_on

You can toggle the syntax on/off with this command:

```
:if exists("g:syntax_on") | syntax off | else | syntax enable | endif
```

To put this into a mapping, you can use:

```
:map <F7> :if exists("g:syntax_on") <Bar>
     \   syntax off <Bar>
     \ else <Bar>
     \   syntax enable <Bar>
     \ endif <CR>
```

[using the <> notation, type this literally]

Details:
The ":syntax" commands are implemented by sourcing a file. To see exactly how this works, look in the file:
command file

```
    :syntax enable      $VIMRUNTIME/syntax/syntax.vim
    :syntax on          $VIMRUNTIME/syntax/syntax.vim
    :syntax manual      $VIMRUNTIME/syntax/manual.vim
    :syntax off         $VIMRUNTIME/syntax/nosyntax.vim
```

Also see syntax-loading.

NOTE: If displaying long lines is slow and switching off syntax highlighting makes it fast, consider setting the 'synmaxcol' option to a lower value.

2. Syntax files :syn-files

The syntax and highlighting commands for one language are normally stored in a syntax file. The name convention is: "{name}.vim". Where {name} is the name of the language, or an abbreviation (to fit the name in 8.3 characters, a requirement in case the file is used on a DOS filesystem).
Examples:

```
        c.vim           perl.vim        java.vim        html.vim
        cpp.vim         sh.vim          csh.vim
```

The syntax file can contain any Ex commands, just like a vimrc file. But the idea is that only commands for a specific language are included. When a language is a superset of another language, it may include the other one, for example, the cpp.vim file could include the c.vim file:

```
:so $VIMRUNTIME/syntax/c.vim
```

The .vim files are normally loaded with an autocommand. For example:

```
:au Syntax c        runtime! syntax/c.vim
:au Syntax cpp   runtime! syntax/cpp.vim
```

These commands are normally in the file $VIMRUNTIME/syntax/synload.vim.

MAKING YOUR OWN SYNTAX FILES mysyntaxfile

When you create your own syntax files, and you want to have Vim use these automatically with ":syntax enable", do this:

1. Create your user runtime directory. You would normally use the first item of the 'runtimepath' option. Example for Unix:

```
mkdir ~/.config/nvim
```

2. Create a directory in there called "syntax". For Unix:

```
mkdir ~/.config/nvim/syntax
```

3. Write the Vim syntax file. Or download one from the internet. Then write it in your syntax directory. For example, for the "mine" syntax:

```
:w ~/.config/nvim/syntax/mine.vim
```

Now you can start using your syntax file manually:

```
:set syntax=mine
```

You don't have to exit Vim to use this.

If you also want Vim to detect the type of file, see new-filetype.

If you are setting up a system with many users and you don't want each user to add the same syntax file, you can use another directory from 'runtimepath'.

ADDING TO AN EXISTING SYNTAX FILE mysyntaxfile-add

If you are mostly satisfied with an existing syntax file, but would like to add a few items or change the highlighting, follow these steps:

1. Create your user directory from 'runtimepath', see above.

2. Create a directory in there called "after/syntax". For Unix:

```
mkdir -p ~/.config/nvim/after/syntax
```

3. Write a Vim script that contains the commands you want to use. For example, to change the colors for the C syntax:

```
highlight cComment ctermfg=Green guifg=Green
```

4. Write that file in the "after/syntax" directory. Use the name of the

   syntax, with ".vim" added. For our C syntax:

```
:w ~/.config/nvim/after/syntax/c.vim
```

That's it. The next time you edit a C file the Comment color will be different. You don't even have to restart Vim.

If you have multiple files, you can use the filetype as the directory name. All the "*.vim" files in this directory will be used, for example:

```
~/.config/nvim/after/syntax/c/one.vim
~/.config/nvim/after/syntax/c/two.vim
```

REPLACING AN EXISTING SYNTAX FILE

mysyntaxfile-replace

If you don't like a distributed syntax file, or you have downloaded a new version, follow the same steps as for mysyntaxfile above. Just make sure that you write the syntax file in a directory that is early in 'runtimepath'. Vim will only load the first syntax file found, assuming that it sets b:current_syntax.

NAMING CONVENTIONS

group-name {group-name} E669 E5248

A syntax group name is to be used for syntax items that match the same kind of thing. These are then linked to a highlight group that specifies the color. A syntax group name doesn't specify any color or attributes itself.

The name for a highlight or syntax group must consist of ASCII letters, digits, underscores, dots, hyphens, or @. As a regexp: [a-zA-Z0-9_.@-]*. The maximum length of a group name is about 200 bytes. E1249

To be able to allow each user to pick their favorite set of colors, there must be preferred names for highlight groups that are common for many languages. These are the suggested group names (if syntax highlighting works properly you can see the actual color, except for "Ignore"):

```
Comment         any comment

Constant        any constant
String          a string constant: "this is a string"
Character       a character constant: 'c', '\n'
Number          a number constant: 234, 0xff
Boolean         a boolean constant: TRUE, false
Regexp          a regular expression constant: /ab*c/
Float           a floating point constant: 2.3e10

Identifier      any variable name
Function        function name (also: methods for classes)

Statement       any statement
Conditional     if, then, else, endif, switch, etc.
Repeat          for, do, while, etc.
Label           case, default, etc.
Operator        "sizeof", "+", "*", etc.
Keyword         any other keyword
Exception       try, catch, throw

PreProc         generic Preprocessor
Include         preprocessor #include
Define          preprocessor #define
Macro           same as Define
PreCondit       preprocessor #if, #else, #endif, etc.

Type            int, long, char, etc.
StorageClass    static, register, volatile, etc.
Structure       struct, union, enum, etc.
Typedef         a typedef

Special         any special symbol
SpecialChar     special character in a constant
Tag             you can use CTRL-] on this
Delimiter       character that needs attention
SpecialComment  special things inside a comment
Debug           debugging statements

Underlined      text that stands out, HTML links
Bold            bold text
Italic          italic text
BoldItalic      bold and italic text
Dimmed          text that is de-emphasized

Ignore          left blank, hidden  hl-Ignore

Error           any erroneous construct

Todo            anything that needs extra attention; mostly the
                keywords TODO FIXME and XXX

Added           added line in a diff
Changed         changed line in a diff
Removed         removed line in a diff
```

Note that highlight group names are not case sensitive. "String" and "string" can be used for the same group.

The following names are reserved and cannot be used as a group name:

```
NONE   ALL   ALLBUT   contains   contained
```

hl-Ignore

When using the Ignore group, you may also consider using the conceal
mechanism. See conceal.

3. Syntax loading procedure syntax-loading

This explains the details that happen when the command ":syntax enable" is
issued. When Vim initializes itself, it finds out where the runtime files are
located. This is used here as the variable $VIMRUNTIME.

":syntax enable" and ":syntax on" do the following:

```
    Source $VIMRUNTIME/syntax/syntax.vim
    |
    +-  Clear out any old syntax by sourcing $VIMRUNTIME/syntax/nosyntax.vim
    |
    +-  Source first syntax/synload.vim in 'runtimepath'
    |   |
    |   +-  Set up syntax autocmds to load the appropriate syntax file when
    |   |   the 'syntax' option is set. synload-1
    |   |
    |   +-  Source the user's optional file, from the mysyntaxfile variable.
    |       This is for backwards compatibility with Vim 5.x only. synload-2
    |
    +-  Do ":filetype on", which does ":runtime! filetype.vim".  It loads any
    |   filetype.vim files found.  It should always Source
    |   $VIMRUNTIME/filetype.vim, which does the following.
    |   |
    |   +-  Install autocmds based on suffix to set the 'filetype' option
    |   |   This is where the connection between file name and file type is
    |   |   made for known file types. synload-3
    |   |
    |   +-  Source the user's optional file, from the myfiletypefile
    |   |   variable.  This is for backwards compatibility with Vim 5.x only.
    |   |   synload-4
    |   |
    |   +-  Install one autocommand which sources scripts.vim when no file
    |   |   type was detected yet. synload-5
    |   |
    |   +-  Source $VIMRUNTIME/menu.vim, to setup the Syntax menu. menu.vim
    |
    +-  Install a FileType autocommand to set the 'syntax' option when a file
    |   type has been detected. synload-6
    |
    +-  Execute syntax autocommands to start syntax highlighting for each
        already loaded buffer.
```

Upon loading a file, Vim finds the relevant syntax file as follows:

```
    Loading the file triggers the BufReadPost autocommands.
    |
    +-  If there is a match with one of the autocommands from synload-3
    |   (known file types) or synload-4 (user's file types), the 'filetype'
    |   option is set to the file type.
    |
    +-  The autocommand at synload-5 is triggered.  If the file type was not
    |   found yet, then scripts.vim is searched for in 'runtimepath'.  This
    |   should always load $VIMRUNTIME/scripts.vim, which does the following.
    |   |
    |   +-  Source the user's optional file, from the myscriptsfile
    |   |   variable.  This is for backwards compatibility with Vim 5.x only.
    |   |
    |   +-  If the file type is still unknown, check the contents of the file,
    |       again with checks like "getline(1) =~ pattern" as to whether the
    |       file type can be recognized, and set 'filetype'.
    |
    +-  When the file type was determined and 'filetype' was set, this
    |   triggers the FileType autocommand synload-6 above.  It sets
    |   'syntax' to the determined file type.
    |
    +-  When the 'syntax' option was set above, this triggers an autocommand
    |   from synload-1 (and synload-2).  This find the main syntax file in
    |   'runtimepath', with this command:
    |           runtime! syntax/<name>.vim
    |
    +-  Any other user installed FileType or Syntax autocommands are
        triggered.  This can be used to change the highlighting for a specific
        syntax.
```

4. Conversion to HTML convert-to-HTML 2html.vim

The old to html converter has been replaced by a Lua version and the
documentation has been moved to :TOhtml.

5. Syntax file remarks :syn-file-remarks

b:current_syntax-variable

Vim stores the name of the syntax that has been loaded in the

"b:current_syntax" variable. You can use this if you want to load other
settings, depending on which syntax is active. Example:

```
:au BufReadPost * if b:current_syntax == "csh"
:au BufReadPost *   do-some-things
:au BufReadPost * endif
```

ABEL **ft-abel-syntax**

ABEL highlighting provides some user-defined options. To enable them, assign
any value to the respective variable. Example:

```
:let abel_obsolete_ok=1
```

To disable them use ":unlet". Example:

```
:unlet abel_obsolete_ok
```

Variable	Highlight
abel_obsolete_ok	obsolete keywords are statements, not errors
abel_cpp_comments_illegal	do not interpret '//' as inline comment leader

ADA

See ft-ada-syntax

ALGOL 68 **algol68** **ft-algol68-syntax**

This syntax file currently targets the Algol 68 Genie project using the
default UPPER stropping regime. It should also be usable in other
environments using the UPPER stropping regime, though somewhat less complete.

Highlighting can be further configured with the following variables.

Variable	Highlight
algol68_no_preludes	no prelude identifiers, procedures or operators

ANT **ft-ant-syntax**

The ant syntax file provides syntax highlighting for javascript and python
by default. Syntax highlighting for other script languages can be installed
by the function AntSyntaxScript(), which takes the tag name as first argument
and the script syntax file name as second argument. Example:

```
:call AntSyntaxScript('perl', 'perl.vim')
```

will install syntax perl highlighting for the following ant code

```
<script language = 'perl'><![CDATA[
    # everything inside is highlighted as perl
]]></script>
```

See mysyntaxfile-add for installing script languages permanently.

APACHE **ft-apache-syntax**

The apache syntax file provides syntax highlighting for Apache HTTP server
version 2.2.3.

ASSEMBLY **asm68k** **ft-asm-syntax** **ft-asmh8300-syntax** **ft-nasm-syntax**

ft-masm-syntax ft-asm68k-syntax

Files matching "*.i" could be Progress or Assembly. If the automatic
detection doesn't work for you, or you don't edit Progress at all, use this in
your startup vimrc:

```
:let filetype_i = "asm"
```

Replace "asm" with the type of assembly you use.

There are many types of assembly languages that all use the same file name
extensions. Therefore you will have to select the type yourself, or add a
line in the assembly file that Vim will recognize. Currently these syntax
files are included:

```
        asm             GNU assembly (usually have .s or .S extension and were
                        already built using C compiler such as GCC or CLANG)
        asm68k          Motorola 680x0 assembly
        asmh8300        Hitachi H-8300 version of GNU assembly
        ia64            Intel Itanium 64
        fasm            Flat assembly (https://flatassembler.net)
        masm            Microsoft assembly (.masm files are compiled with
                        Microsoft's Macro Assembler.  This is only supported
                        for x86, x86_64, ARM and AARCH64 CPU families)
        nasm            Netwide assembly
```

```
        tasm            Turbo Assembly (with opcodes 80x86 up to Pentium, and
                        MMX)
        pic             PIC assembly (currently for PIC16F84)
```

The most flexible is to add a line in your assembly file containing:

```
asmsyntax=nasm
```

Replace "nasm" with the name of the real assembly syntax. This line must be one of the first five lines in the file. No non-white text must be immediately before or after this text. Note that specifying asmsyntax=foo is equivalent to setting ft=foo in a modeline, and that in case of a conflict between the two settings the one from the modeline will take precedence (in particular, if you have ft=asm in the modeline, you will get the GNU syntax highlighting regardless of what is specified as asmsyntax).

The syntax type can always be overruled for a specific buffer by setting the b:asmsyntax variable:

```
:let b:asmsyntax = "nasm"
```

If b:asmsyntax is not set, either automatically or by hand, then the value of the global variable asmsyntax is used. This can be seen as a default assembly language:

```
:let asmsyntax = "nasm"
```

As a last resort, if nothing is defined, the "asm" syntax is used.

Netwide assembler (nasm.vim) optional highlighting

To enable a feature:

```
:let   {variable}=1|set syntax=nasm
```

To disable a feature:

```
:unlet {variable}  |set syntax=nasm
```

Variable	**Highlight**
nasm_loose_syntax	unofficial parser allowed syntax not as Error (parser dependent; not recommended)
nasm_ctx_outside_macro	contexts outside macro not as Error
nasm_no_warn	potentially risky syntax not as ToDo

ASTRO ft-astro-syntax

Configuration

The following variables control certain syntax highlighting features.
You can add them to your .vimrc.

To enable TypeScript and TSX for ".astro" files (default "disable"):

```
let g:astro_typescript = "enable"
```

To enable Stylus for ".astro" files (default "disable"):

```
let g:astro_stylus = "enable"
```

NOTE: You need to install an external plugin to support stylus in astro files.

ASPPERL ft-aspperl-syntax

ASPVBS ft-aspvbs-syntax

*.asp and *.asa files could be either Perl or Visual Basic script. Since it's hard to detect this you can set two global variables to tell Vim what you are using. For Perl script use:

```
:let g:filetype_asa = "aspperl"
:let g:filetype_asp = "aspperl"
```

For Visual Basic use:

```
:let g:filetype_asa = "aspvbs"
:let g:filetype_asp = "aspvbs"
```

ASYMPTOTE ft-asy-syntax

By default, only basic Asymptote keywords are highlighted. To highlight extended geometry keywords:

```
:let g:asy_syn_plain = 1
```

and for highlighting keywords related to 3D constructions:

```
:let g:asy_syn_three = 1
```

By default, Asymptote-defined colors (e.g: lightblue) are highlighted. To highlight TeX-defined colors (e.g: BlueViolet) use:

```
:let g:asy_syn_texcolors = 1
```

or for Xorg colors (e.g: AliceBlue):

```
:let g:asy_syn_x11colors = 1
```

BAAN **baan-syntax**

The baan.vim gives syntax support for BaanC of release BaanIV up to SSA ERP LN for both 3 GL and 4 GL programming. Large number of standard defines/constants are supported.

Some special violation of coding standards will be signalled when one specify in ones init.vim:

```
let baan_code_stds=1
```

baan-folding

Syntax folding can be enabled at various levels through the variables mentioned below (Set those in your init.vim). The more complex folding on source blocks and SQL can be CPU intensive.

To allow any folding and enable folding at function level use:

```
let baan_fold=1
```

Folding can be enabled at source block level as if, while, for ,... The indentation preceding the begin/end keywords has to match (spaces are not considered equal to a tab).

```
let baan_fold_block=1
```

Folding can be enabled for embedded SQL blocks as SELECT, SELECTDO, SELECTEMPTY, ... The indentation preceding the begin/end keywords has to match (spaces are not considered equal to a tab).

```
let baan_fold_sql=1
```

Note: Block folding can result in many small folds. It is suggested to :set the options 'foldminlines' and 'foldnestmax' in init.vim or use :setlocal in .../after/syntax/baan.vim (see after-directory). Eg:

```
set foldminlines=5
set foldnestmax=6
```

BASIC **ft-basic-syntax** **ft-vb-syntax**

Both Visual Basic and "normal" BASIC use the extension ".bas". To detect which one should be used, Vim checks for the string "VB_Name" in the first five lines of the file. If it is not found, filetype will be "basic", otherwise "vb". Files with the ".frm" extension will always be seen as Visual Basic.

If the automatic detection doesn't work for you or you only edit, for example, FreeBASIC files, use this in your startup vimrc:

```
:let filetype_bas = "freebasic"
```

C ft-c-syntax

A few things in C highlighting are optional. To enable them assign any value (including zero) to the respective variable. Example:

```
:let c_comment_strings = 1
:let c_no_bracket_error = 0
```

To disable them use :unlet. Example:

```
:unlet c_comment_strings
```

Setting the value to zero doesn't work!

An alternative is to switch to the C++ highlighting:

```
:set filetype=cpp
```

Variable	**Highlight**
c_gnu	GNU gcc specific items
c_comment_strings	strings and numbers inside a comment
c_space_errors	trailing white space and spaces before a <Tab>
c_no_trail_space_error	... but no trailing spaces
c_no_tab_space_error	... but no spaces before a <Tab>
c_no_bracket_error	don't highlight {}; inside [] as errors
c_no_curly_error	don't highlight {}; inside [] and () as errors; ...except { and } in first column Default is to highlight them, otherwise you can't spot a missing ")".
c_curly_error	highlight a missing } by finding all pairs; this forces syncing from the start of the file, can be slow
c_no_ansi	don't do standard ANSI types and constants
c_ansi_typedefs	... but do standard ANSI types
c_ansi_constants	... but do standard ANSI constants
c_no_utf	don't highlight \u and \U in strings
c_syntax_for_h	use C syntax for *.h files instead of C++/ObjC/ObjC++ (**NOTE:** This variable is deprecated and no longer necessary, as *.h files now default to C, unless the file contains C++ or Objective-C syntax. If the automated detection fails, the default filetype can be adjusted using g:filetype_h.)
c_no_if0	don't highlight "#if 0" blocks as comments
c_no_cformat	don't highlight %-formats in strings
c_no_c99	don't highlight C99 standard items
c_no_c11	don't highlight C11 standard items
c_no_c23	don't highlight C23 standard items
c_no_c29	don't highlight C29 standard items
c_no_bsd	don't highlight BSD specific types
c_functions	highlight function calls and definitions
c_function_pointers	highlight function pointers definitions

When 'foldmethod' is set to "syntax" then /* */ comments and { } blocks will become a fold. If you don't want comments to become a fold use:

```
:let c_no_comment_fold = 1
```

"#if 0" blocks are also folded, unless:

```
:let c_no_if0_fold = 1
```

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with CTRL-L, try setting the "c_minlines" internal variable to a larger number:

```
:let c_minlines = 100
```

This will make the syntax synchronization start 100 lines before the first displayed line. The default value is 50 (15 when c_no_if0 is set). The disadvantage of using a larger number is that redrawing can become slow.

When using the "#if 0" / "#endif" comment highlighting, notice that this only works when the "#if 0" is within "c_minlines" from the top of the window. If you have a long "#if 0" construct it will not be highlighted correctly.

To match extra items in comments, use the cCommentGroup cluster.
Example:

```
:au Syntax c call MyCadd()
:function MyCadd()
:  syn keyword cMyItem contained Ni
:  syn cluster cCommentGroup add=cMyItem
:  hi link cMyItem Title
:endfun
```

ANSI constants will be highlighted with the "cConstant" group. This includes "NULL", "SIG_IGN" and others. But not "TRUE", for example, because this is not in the ANSI standard. If you find this confusing, remove the cConstant highlighting:

```
:hi link cConstant NONE
```

If you see '{' and '}' highlighted as an error where they are OK, reset the highlighting for cErrInParen and cErrInBracket.

If you want to use folding in your C files, you can add these lines in a file in the "after" directory in 'runtimepath'. For Unix this would be ~/.config/nvim/after/syntax/c.vim.

```
syn sync fromstart
set foldmethod=syntax
```

CANGJIE

ft-cangjie-syntax

This file provides syntax highlighting for the Cangjie programming language, a new-generation language oriented to full-scenario intelligence.

All highlighting is enabled by default. To disable highlighting for a specific group, set the corresponding variable to 0 in your vimrc.
All options to disable highlighting are:

```
:let g:cangjie_builtin_color = 0
:let g:cangjie_comment_color = 0
:let g:cangjie_identifier_color = 0
:let g:cangjie_keyword_color = 0
:let g:cangjie_macro_color = 0
:let g:cangjie_number_color = 0
:let g:cangjie_operator_color = 0
:let g:cangjie_string_color = 0
:let g:cangjie_type_color = 0
```

CH

ft-ch-syntax

C/C++ interpreter. Ch has similar syntax highlighting to C and builds upon the C syntax file. See ft-c-syntax for all the settings that are available for C.

By setting a variable you can tell Vim to use Ch syntax for *.h files, instead of C or C++:

```
:let g:filetype_h = 'ch'
```

CHILL

ft-chill-syntax

Chill syntax highlighting is similar to C. See ft-c-syntax for all the settings that are available. Additionally there is:

```
chill_space_errors      like c_space_errors
chill_comment_string    like c_comment_strings
chill_minlines          like c_minlines
```

CHANGELOG

ft-changelog-syntax

ChangeLog supports highlighting spaces at the start of a line.
If you do not like this, add following line to your vimrc:

```
let g:changelog_spacing_errors = 0
```

This works the next time you edit a changelog file. You can also use "b:changelog_spacing_errors" to set this per buffer (before loading the syntax file).

You can change the highlighting used, e.g., to flag the spaces as an error:

```
:hi link ChangelogError Error
```

Or to avoid the highlighting:

```
:hi link ChangelogError NONE
```

This works immediately.

CLOJURE

ft-clojure-syntax

g:clojure_syntax_keywords

Syntax highlighting of public vars in "clojure.core" is provided by default, but additional symbols can be highlighted by adding them to the g:clojure_syntax_keywords variable. The value should be a Dictionary of syntax group names, each containing a List of identifiers.

```
let g:clojure_syntax_keywords = {
    \   'clojureMacro': ["defproject", "defcustom"],
    \   'clojureFunc': ["string/join", "string/replace"]
    \ }
```

Refer to the Clojure syntax script for valid syntax group names.

There is also b:clojure_syntax_keywords which is a buffer-local variant of this variable intended for use by plugin authors to highlight symbols dynamically.

By setting the b:clojure_syntax_without_core_keywords variable, vars from "clojure.core" will not be highlighted by default. This is useful for namespaces that have set (:refer-clojure :only [])

g:clojure_fold

Setting g:clojure_fold to 1 will enable the folding of Clojure code. Any list, vector or map that extends over more than one line can be folded using the standard Vim fold-commands.

g:clojure_discard_macro

Set this variable to 1 to enable basic highlighting of Clojure's "discard reader macro".

```
#_(defn foo [x]
    (println x))
```

Note that this option will not correctly highlight stacked discard macros (e.g. #_#_).

COBOL **ft-cobol-syntax**

COBOL highlighting has different needs for legacy code than it does for fresh development. This is due to differences in what is being done (maintenance versus development) and other factors. To enable legacy code highlighting, add this line to your vimrc:

```
:let cobol_legacy_code = 1
```

To disable it again, use this:

```
:unlet cobol_legacy_code
```

COLD FUSION **ft-coldfusion-syntax**

The ColdFusion has its own version of HTML comments. To turn on ColdFusion comment highlighting, add the following line to your startup file:

```
:let html_wrong_comments = 1
```

The ColdFusion syntax file is based on the HTML syntax file.

CPP **ft-cpp-syntax**

Most things are the same as ft-c-syntax.

Variable	Highlight
cpp_no_cpp11	don't highlight C++11 standard items
cpp_no_cpp14	don't highlight C++14 standard items
cpp_no_cpp17	don't highlight C++17 standard items
cpp_no_cpp20	don't highlight C++20 standard items
cpp_no_cpp23	don't highlight C++23 standard items
cpp_no_cpp26	don't highlight C++26 standard items

CSH **ft-csh-syntax**

This covers the shell named "csh". Note that on some systems tcsh is actually used.

Detecting whether a file is csh or tcsh is notoriously hard. Some systems symlink /bin/csh to /bin/tcsh, making it almost impossible to distinguish between csh and tcsh. In case VIM guesses wrong you can set the "filetype_csh" variable. For using csh: g:filetype_csh

```
:let g:filetype_csh = "csh"
```

For using tcsh:

```
:let g:filetype_csh = "tcsh"
```

Any script with a tcsh extension or a standard tcsh filename (.tcshrc, tcsh.tcshrc, tcsh.login) will have filetype tcsh. All other tcsh/csh scripts will be classified as tcsh, UNLESS the "filetype_csh" variable exists. If the "filetype_csh" variable exists, the filetype will be set to the value of the variable.

CSV **ft-csv-syntax**

If you change the delimiter of a CSV file, its syntax highlighting will no longer match the changed file content. You will need to unlet the following variable:

```
:unlet b:csv_delimiter
```

And afterwards save and reload the file:

```
:w
:e
```

Now the syntax engine should determine the newly changed CSV delimiter.

CYNLIB ft-cynlib-syntax

Cynlib files are C++ files that use the Cynlib class library to enable
hardware modelling and simulation using C++. Typically Cynlib files have a
.cc or a .cpp extension, which makes it very difficult to distinguish them
from a normal C++ file. Thus, to enable Cynlib highlighting for .cc files,
add this line to your vimrc file:

```
:let cynlib_cyntax_for_cc=1
```

Similarly for cpp files (this extension is only usually used in Windows)

```
:let cynlib_cyntax_for_cpp=1
```

To disable these again, use this:

```
:unlet cynlib_cyntax_for_cc
:unlet cynlib_cyntax_for_cpp
```

CWEB ft-cweb-syntax

Files matching "*.w" could be Progress or cweb. If the automatic detection
doesn't work for you, or you don't edit Progress at all, use this in your
startup vimrc:

```
:let filetype_w = "cweb"
```

CSHARP ft-cs-syntax

C# raw string literals may use any number of quote marks to encapsulate the
block, and raw interpolated string literals may use any number of braces to
encapsulate the interpolation, e.g.

```
$$$"""Hello {{{name}}}"""
```

By default, Vim highlights 3-8 quote marks, and 1-8 interpolation braces.
The maximum numbers of quotes and braces recognized can configured using the
following variables:

Variable	Default
g:cs_raw_string_quote_count	8
g:cs_raw_string_interpolation_brace_count	8

DART ft-dart-syntax

Dart is an object-oriented, typed, class defined, garbage collected language
used for developing mobile, desktop, web, and back-end applications. Dart
uses a C-like syntax derived from C, Java, and JavaScript, with features
adopted from Smalltalk, Python, Ruby, and others.

More information about the language and its development environment at the
official Dart language website at https://dart.dev

dart.vim syntax detects and highlights Dart statements, reserved words,
type declarations, storage classes, conditionals, loops, interpolated values,
and comments. There is no support idioms from Flutter or any other Dart
framework.

Changes, fixes? Submit an issue or pull request via:

https://github.com/pr3d4t0r/dart-vim-syntax/

DESKTOP ft-desktop-syntax

Primary goal of this syntax file is to highlight .desktop and .directory files
according to freedesktop.org standard:
https://specifications.freedesktop.org/desktop-entry-spec/latest/
To highlight nonstandard extensions that does not begin with X-, set

```
let g:desktop_enable_nonstd = 1
```

Note that this may cause wrong highlight.
To highlight KDE-reserved features, set

```
let g:desktop_enable_kde = 1
```

g:desktop_enable_kde follows g:desktop_enable_nonstd if not supplied

DIFF diff.vim

The diff highlighting normally finds translated headers. This can be slow if
there are very long lines in the file. To disable translations:

```
:let diff_translations = 0
```

Also see diff-slow.

DIRCOLORS ft-dircolors-syntax

The dircolors utility highlighting definition has one option. It exists to
provide compatibility with the Slackware GNU/Linux distributions version of
the command. It adds a few keywords that are generally ignored by most
versions. On Slackware systems, however, the utility accepts the keywords and
uses them for processing. To enable the Slackware keywords add the following
line to your startup file:

```
let dircolors_is_slackware = 1
```

DOCBOOK ft-docbk-syntax docbook

DOCBOOK XML ft-docbkxml-syntax

DOCBOOK SGML ft-docbksgml-syntax

There are two types of DocBook files: SGML and XML. To specify what type you
are using the "b:docbk_type" variable should be set. Vim does this for you
automatically if it can recognize the type. When Vim can't guess it the type
defaults to XML.
You can set the type manually:

```
:let b:docbk_type = "sgml"
```

or:

```
:let b:docbk_type = "xml"
```

You need to do this before loading the syntax file, which is complicated.
Simpler is setting the filetype to "docbkxml" or "docbksgml":

```
:set filetype=docbksgml
```

or:

```
:set filetype=docbkxml
```

You can specify the DocBook version for the current buffer:

```
:let b:docbk_ver = 3
```

When "b:docbk_ver" is not set, "g:docbk_ver" is used as a global fallback:

```
:let g:docbk_ver = 3
```

When neither variable is set, version 4 is used.

DOSBATCH ft-dosbatch-syntax

Select the set of Windows Command interpreter extensions that should be
supported with the variable dosbatch_cmdextversion. For versions of Windows
NT (before Windows 2000) this should have the value of 1. For Windows 2000
and later it should be 2.
Select the version you want with the following line:

```
:let dosbatch_cmdextversion = 1
```

If this variable is not defined it defaults to a value of 2 to support
Windows 2000 and later.

The original MS-DOS supports an idiom of using a double colon (::) as an
alternative way to enter a comment line. This idiom can be used with the
current Windows Command Interpreter, but it can lead to problems when used
inside (...) command blocks. You can find a discussion about this on
Stack Overflow -

https://stackoverflow.com/questions/12407800/which-comment-style-should-i-use-in-batch-files

To allow the use of the :: idiom for comments in command blocks with the
Windows Command Interpreter set the dosbatch_colons_comment variable to
anything:

```
:let dosbatch_colons_comment = 1
```

If this variable is set then a :: comment that is the last line in a command
block will be highlighted as an error.

There is an option that covers whether *.btm files should be detected as type
"dosbatch" (MS-DOS batch files) or type "btm" (4DOS batch files). The latter
is used by default. You may select the former with the following line:

```
:let g:dosbatch_syntax_for_btm = 1
```

If this variable is undefined or zero, btm syntax is selected.

DOXYGEN doxygen-syntax

Doxygen generates code documentation using a special documentation format
(similar to Javadoc). This syntax script adds doxygen highlighting to c, cpp,
idl and php files, and should also work with java.

There are a few of ways to turn on doxygen formatting. It can be done
explicitly or in a modeline by appending '.doxygen' to the syntax of the file.
Example:

```
:set syntax=c.doxygen
```

or

```
// vim:syntax=c.doxygen
```

It can also be done automatically for C, C++, C#, IDL and PHP files by setting
the global or buffer-local variable load_doxygen_syntax. This is done by
adding the following to your vimrc.

```
:let g:load_doxygen_syntax=1
```

There are a couple of variables that have an effect on syntax highlighting,
and are to do with non-standard highlighting options.

Variable	Default	Effect
g:doxygen_enhanced_color		
g:doxygen_enhanced_colour	0	Use non-standard highlighting for doxygen comments.
doxygen_my_rendering	0	Disable rendering of HTML bold, italic and html_my_rendering underline.
doxygen_javadoc_autobrief	1	Set to 0 to disable javadoc autobrief colour highlighting.
doxygen_end_punctuation	'[.]'	Set to regexp match for the ending punctuation of brief

There are also some highlight groups worth mentioning as they can be useful in
configuration.

Highlight	Effect
doxygenErrorComment	The colour of an end-comment when missing punctuation in a code, verbatim or dot section
doxygenLinkError	The colour of an end-comment when missing the \endlink from a \link section.

DTD ft-dtd-syntax

The DTD syntax highlighting is case sensitive by default. To disable
case-sensitive highlighting, add the following line to your startup file:

```
:let dtd_ignore_case=1
```

The DTD syntax file will highlight unknown tags as errors. If
this is annoying, it can be turned off by setting:

```
:let dtd_no_tag_errors=1
```

before sourcing the dtd.vim syntax file.
Parameter entity names are highlighted in the definition using the
'Type' highlighting group and 'Comment' for punctuation and '%'.
Parameter entity instances are highlighted using the 'Constant'
highlighting group and the 'Type' highlighting group for the
delimiters % and ;. This can be turned off by setting:

```
:let dtd_no_param_entities=1
```

The DTD syntax file is also included by xml.vim to highlight included dtd's.

EIFFEL

ft-eiffel-syntax

While Eiffel is not case-sensitive, its style guidelines are, and the
syntax highlighting file encourages their use. This also allows to
highlight class names differently. If you want to disable case-sensitive
highlighting, add the following line to your startup file:

```
:let eiffel_ignore_case=1
```

Case still matters for class names and TODO marks in comments.

Conversely, for even stricter checks, add one of the following lines:

```
:let eiffel_strict=1
:let eiffel_pedantic=1
```

Setting eiffel_strict will only catch improper capitalization for the
five predefined words "Current", "Void", "Result", "Precursor", and
"NONE", to warn against their accidental use as feature or class names.

Setting eiffel_pedantic will enforce adherence to the Eiffel style
guidelines fairly rigorously (like arbitrary mixes of upper- and
lowercase letters as well as outdated ways to capitalize keywords).

If you want to use the lower-case version of "Current", "Void",
"Result", and "Precursor", you can use

```
:let eiffel_lower_case_predef=1
```

instead of completely turning case-sensitive highlighting off.

Support for ISE's proposed new creation syntax that is already
experimentally handled by some compilers can be enabled by:

```
:let eiffel_ise=1
```

Finally, some vendors support hexadecimal constants. To handle them, add

```
:let eiffel_hex_constants=1
```

to your startup file.

EUPHORIA

ft-euphoria-syntax

Two syntax highlighting files exist for Euphoria. One for Euphoria
version 3.1.1, which is the default syntax highlighting file, and one for
Euphoria version 4.0.5 or later.

Euphoria version 3.1.1 (https://www.rapideuphoria.com/ link seems dead) is
still necessary for developing applications for the DOS platform, which
Euphoria version 4 (https://www.openeuphoria.org/) does not support.

The following file extensions are auto-detected as Euphoria file type:

```
*.e, *.eu, *.ew, *.ex, *.exu, *.exw
*.E, *.EU, *.EW, *.EX, *.EXU, *.EXW
```

To select syntax highlighting file for Euphoria, as well as for
auto-detecting the *.e and *.E file extensions as Euphoria file type,
add the following line to your startup file:

```
:let g:filetype_euphoria = "euphoria3"
```

       or

```
:let g:filetype_euphoria = "euphoria4"
```

Elixir and Euphoria share the *.ex file extension. If the filetype is
specifically set as Euphoria with the g:filetype_euphoria variable, or the
file is determined to be Euphoria based on keywords in the file, then the
filetype will be set as Euphoria. Otherwise, the filetype will default to
Elixir.

ERLANG

ft-erlang-syntax

Erlang is a functional programming language developed by Ericsson. Files with
the following extensions are recognized as Erlang files: erl, hrl, yaws.

Vim highlights triple-quoted docstrings as comments by default.

If you want triple-quoted docstrings highlighted as Markdown, add the
following line to your vimrc:

```
:let g:erlang_use_markdown_for_docs = 1
```

The plain text inside the docstrings (that is, the characters that are not
highlighted by the Markdown syntax) is still highlighted as a comment.

If you want to highlight the plain text inside the docstrings using a different highlight group, add the following line to your vimrc (the example highlights plain text using the String highlight group):

```
:let g:erlang_docstring_default_highlight = 'String'
```

If you don't enable Markdown, this line highlights the full docstrings according to the specified highlight group.

Use the following line to disable highlighting for the plain text:

```
:let g:erlang_docstring_default_highlight = ''
```

Configuration examples:

```
" Highlight docstrings as Markdown.
:let g:erlang_use_markdown_for_docs = 1

" 1. Highlight Markdown elements in docstrings as Markdown.
" 2. Highlight the plain text in docstrings as String.
:let g:erlang_use_markdown_for_docs = 1
:let g:erlang_docstring_default_highlight = 'String'

" Highlight docstrings as strings (no Markdown).
:let g:erlang_docstring_default_highlight = 'String'

" 1. Highlight Markdown elements in docstrings as Markdown.
" 2. Don't highlight the plain text in docstrings.
:let g:erlang_use_markdown_for_docs = 1
:let g:erlang_docstring_default_highlight = ''
```

ELIXIR ft-elixir-syntax

Elixir is a dynamic, functional language for building scalable and maintainable applications.

The following file extensions are auto-detected as Elixir file types:

```
*.ex, *.exs, *.eex, *.leex, *.lock
```

Elixir and Euphoria share the *.ex file extension. If the filetype is specifically set as Euphoria with the g:filetype_euphoria variable, or the file is determined to be Euphoria based on keywords in the file, then the filetype will be set as Euphoria. Otherwise, the filetype will default to Elixir.

FLEXWIKI ft-flexwiki-syntax

FlexWiki is an ASP.NET-based wiki package available at www.flexwiki.com
NOTE: This site currently doesn't work, on Wikipedia is mentioned that development stopped in 2009.

Syntax highlighting is available for the most common elements of FlexWiki syntax. The associated ftplugin script sets some buffer-local options to make editing FlexWiki pages more convenient. FlexWiki considers a newline as the start of a new paragraph, so the ftplugin sets 'tw'=0 (unlimited line length), 'wrap' (wrap long lines instead of using horizontal scrolling), 'linebreak' (to wrap at a character in 'breakat' instead of at the last char on screen), and so on. It also includes some keymaps that are disabled by default.

If you want to enable the keymaps that make "j" and "k" and the cursor keys move up and down by display lines, add this to your vimrc:

```
:let flexwiki_maps = 1
```

FORM ft-form-syntax

The coloring scheme for syntax elements in the FORM file uses the default modes Conditional, Number, Statement, Comment, PreProc, Type, and String, following the language specifications in 'Symbolic Manipulation with FORM' by J.A.M. Vermaseren, CAN, Netherlands, 1991.

If you want to include your own changes to the default colors, you have to redefine the following syntax groups:

- formConditional
- formNumber
- formStatement
- formHeaderStatement

- formComment
- formPreProc
- formDirective
- formType
- formString

Note that the form.vim syntax file implements FORM preprocessor commands and directives per default in the same syntax group.

A predefined enhanced color mode for FORM is available to distinguish between header statements and statements in the body of a FORM program. To activate this mode define the following variable in your vimrc file

```
:let form_enhanced_color=1
```

The enhanced mode also takes advantage of additional color features for a dark gvim display. Here, statements are colored LightYellow instead of Yellow, and conditionals are LightBlue for better distinction.

Both Visual Basic and FORM use the extension ".frm". To detect which one should be used, Vim checks for the string "VB_Name" in the first five lines of the file. If it is found, filetype will be "vb", otherwise "form".

If the automatic detection doesn't work for you or you only edit, for example, FORM files, use this in your startup vimrc:

```
:let filetype_frm = "form"
```

FORTH ft-forth-syntax

Files matching "*.f" could be Fortran or Forth and those matching "*.fs" could be F# or Forth. If the automatic detection doesn't work for you, or you don't edit F# or Fortran at all, use this in your startup vimrc:

```
:let filetype_f  = "forth"
:let filetype_fs = "forth"
```

FORTRAN ft-fortran-syntax

Default highlighting and dialect
Vim highlights according to Fortran 2023 (the most recent standard). This choice should be appropriate for most users most of the time because Fortran 2023 is almost a superset of previous versions (Fortran 2018, 2008, 2003, 95, 90, 77, and 66). A few legacy constructs deleted or declared obsolescent, respectively, in recent Fortran standards are highlighted as errors and todo items.

The syntax script no longer supports Fortran dialects. The variable fortran_dialect is now silently ignored. Since computers are much faster now, the variable fortran_more_precise is no longer needed and is silently ignored.

Fortran source code form
Fortran code can be in either fixed or free source form. Note that the syntax highlighting will not be correct if the form is incorrectly set.

When you create a new Fortran file, the syntax script assumes fixed source form. If you always use free source form, then

```
:let fortran_free_source=1
```

If you always use fixed source form, then

```
:let fortran_fixed_source=1
```

If the form of the source code depends, in a non-standard way, upon the file extension, then it is most convenient to set fortran_free_source in a ftplugin file. For more information on ftplugin files, see ftplugin. Note that this will work only if the "filetype plugin indent on" command precedes the "syntax on" command in your .vimrc file.

When you edit an existing Fortran file, the syntax script will assume free source form if the fortran_free_source variable has been set, and assumes fixed source form if the fortran_fixed_source variable has been set. Suppose neither of these variables have been set. In that case, the syntax script attempts to determine which source form has been used by examining the file extension using conventions common to the ifort, gfortran, Cray, NAG, and PathScale compilers (.f, .for, .f77 for fixed-source, .f90, .f95, .f03, .f08 for free-source). No default is used for the .fpp and .ftn file extensions

because different compilers treat them differently. If none of this works, then the script examines the first five columns of the first 500 lines of your file. If no signs of free source form are detected, then the file is assumed to be in fixed source form. The algorithm should work in the vast majority of cases. In some cases, such as a file that begins with 500 or more full-line comments, the script may incorrectly decide that the code is in fixed form. If that happens, just add a non-comment statement beginning anywhere in the first five columns of the first twenty-five lines, save (:w), and then reload (:e!) the file.

Vendor extensions
Fixed-form Fortran requires a maximum line length of 72 characters but the script allows a maximum line length of 80 characters as do all compilers created in the last three decades. An even longer line length of 132 characters is allowed if you set the variable fortran_extended_line_length with a command such as

```
:let fortran_extended_line_length=1
```

If you want additional highlighting of the CUDA Fortran extensions, you should set the variable fortran_CUDA with a command such as

```
:let fortran_CUDA=1
```

To activate recognition of some common, non-standard, vendor-supplied intrinsics, you should set the variable fortran_vendor_intrinsics with a command such as

```
:let fortran_vendor_intrinsics=1
```

Tabs in Fortran files
Tabs are not recognized by the Fortran standards. Tabs are not a good idea in fixed format Fortran source code which requires fixed column boundaries. Therefore, tabs are marked as errors. Nevertheless, some programmers like using tabs. If your Fortran files contain tabs, then you should set the variable fortran_have_tabs in your vimrc with a command such as

```
:let fortran_have_tabs=1
```

Unfortunately, the use of tabs will mean that the syntax file will not be able to detect incorrect margins.

Syntax folding of Fortran files
Vim will fold your file using foldmethod=syntax, if you set the variable fortran_fold in your .vimrc with a command such as

```
:let fortran_fold=1
```

to instruct the syntax script to define fold regions for program units, that is main programs starting with a program statement, subroutines, function subprograms, modules, submodules, blocks of comment lines, and block data units. Block, interface, associate, critical, type definition, and change team constructs will also be folded. If you also set the variable fortran_fold_conditionals with a command such as

```
:let fortran_fold_conditionals=1
```

then fold regions will also be defined for do loops, if blocks, select case, select type, and select rank constructs. Note that defining fold regions can be slow for large files.

The syntax/fortran.vim script contains embedded comments that tell you how to comment and/or uncomment some lines to (a) activate recognition of some non-standard, vendor-supplied intrinsics and (b) to prevent features deleted or declared obsolescent in the 2008 standard from being highlighted as todo items.

Limitations
Parenthesis checking does not catch too few closing parentheses. Hollerith strings are not recognized. Some keywords may be highlighted incorrectly because Fortran90 has no reserved words.

For further information related to Fortran, see ft-fortran-indent and ft-fortran-plugin.

FREEBASIC ft-freebasic-syntax

FreeBASIC files will be highlighted differently for each of the four available dialects, "fb", "qb", "fblite" and "deprecated". See ft-freebasic-plugin for how to select the correct dialect.

Highlighting is further configurable via the following variables.

Variable	Highlight
freebasic_no_comment_fold	disable multiline comment folding
freebasic_operators	non-alpha operators
freebasic_space_errors	trailing white space and spaces before a <Tab>
freebasic_type_suffixes	QuickBASIC style type suffixes

FVWM CONFIGURATION FILES ft-fvwm-syntax

In order for Vim to recognize Fvwm configuration files that do not match the patterns fvwmrc or fvwm2rc , you must put additional patterns appropriate to your system in your myfiletypes.vim file. For these patterns, you must set the variable "b:fvwm_version" to the major version number of Fvwm, and the 'filetype' option to fvwm.

For example, to make Vim identify all files in /etc/X11/fvwm2/ as Fvwm2 configuration files, add the following:

```
:au! BufNewFile,BufRead /etc/X11/fvwm2/*  let b:fvwm_version = 2 |
                                        \ set filetype=fvwm
```

GSP ft-gsp-syntax

The default coloring style for GSP pages is defined by ft-html-syntax, and the coloring for java code (within java tags or inline between backticks) is defined by ft-java-syntax. The following HTML groups defined in ft-html-syntax are redefined to incorporate and highlight inline java code:

```
htmlString
htmlValue
htmlEndTag
htmlTag
htmlTagN
```

Highlighting should look fine most of the places where you'd see inline java code, but in some special cases it may not. To add another HTML group where you will have inline java code where it does not highlight correctly, just copy the line you want from ft-html-syntax and add gspJava to the contains clause.

The backticks for inline java are highlighted according to the htmlError group to make them easier to see.

GDB ft-gdb-syntax

The GDB syntax file provides syntax folding (see :syn-fold) for comments and block statements. This can be enabled with:

```
:set foldmethod=syntax
```

GROFF ft-groff-syntax

The groff syntax file is a wrapper for ft-nroff-syntax, see the notes under that heading for examples of use and configuration. The purpose of this wrapper is to set up groff syntax extensions by setting the filetype from a modeline or in a personal filetype definitions file (see filetype.txt).

HASKELL ft-haskell-syntax

The Haskell syntax files support plain Haskell code as well as literate Haskell code, the latter in both Bird style and TeX style. The Haskell syntax highlighting will also highlight C preprocessor directives.

If you want to highlight delimiter characters (useful if you have a light-coloured background), add to your vimrc:

```
:let hs_highlight_delimiters = 1
```

To treat True and False as keywords as opposed to ordinary identifiers, add:

```
:let hs_highlight_boolean = 1
```

To also treat the names of primitive types as keywords:

```
:let hs_highlight_types = 1
```

And to treat the names of even more relatively common types as keywords:

```
:let hs_highlight_more_types = 1
```

If you want to highlight the names of debugging functions, put in your vimrc:

```
:let hs_highlight_debug = 1
```

The Haskell syntax highlighting also highlights C preprocessor
directives, and flags lines that start with # but are not valid
directives as erroneous. This interferes with Haskell's syntax for
operators, as they may start with #. If you want to highlight those
as operators as opposed to errors, put in your vimrc:

```
:let hs_allow_hash_operator = 1
```

The syntax highlighting for literate Haskell code will try to
automatically guess whether your literate Haskell code contains
TeX markup or not, and correspondingly highlight TeX constructs
or nothing at all. You can override this globally by putting
in your vimrc

```
:let lhs_markup = none
```

for no highlighting at all, or

```
:let lhs_markup = tex
```

to force the highlighting to always try to highlight TeX markup.
For more flexibility, you may also use buffer local versions of
this variable, so e.g.

```
:let b:lhs_markup = tex
```

will force TeX highlighting for a particular buffer. It has to be
set before turning syntax highlighting on for the buffer or
loading a file.

HTML **ft-html-syntax**

The coloring scheme for tags in the HTML file works as follows.

The <> of opening tags are colored differently than the </> of a closing tag.
This is on purpose! For opening tags the 'Function' color is used, while for
closing tags the 'Identifier' color is used (See syntax.vim to check how those
are defined for you)

Known tag names are colored the same way as statements in C. Unknown tag
names are colored with the same color as the <> or </> respectively which
makes it easy to spot errors

Note that the same is true for argument (or attribute) names. Known attribute
names are colored differently than unknown ones.

Some HTML tags are used to change the rendering of text. The following tags
are recognized by the html.vim syntax coloring file and change the way normal
text is shown: <B> <I> <U> <EM> <STRONG> (<EM> is used as an alias for <I>,
while <STRONG> as an alias for <B>), <H1> - <H6>, <HEAD>, <TITLE> and <A>, but
only if used as a link (that is, it must include a href as in
<A href="somefile.html">).

If you want to change how such text is rendered, you must redefine the
following syntax groups:

- htmlBold
- htmlBoldUnderline
- htmlBoldUnderlineItalic
- htmlUnderline
- htmlUnderlineItalic
- htmlItalic
- htmlTitle for titles
- htmlH1 - htmlH6 for headings

To make this redefinition work you must redefine them all with the exception
of the last two (htmlTitle and htmlH[1-6], which are optional) and define the
following variable in your vimrc (this is due to the order in which the files
are read during initialization)

```
:let html_my_rendering=1
```

If you'd like to see an example download mysyntax.vim at
https://web.archive.org/web/20241129015117/https://www.fleiner.com/vim/download.html

You can also disable this rendering by adding the following line to your
vimrc file:

```
:let html_no_rendering=1
```

By default Vim starts parsing 1.5 times "html_minlines" lines before the first
displayed line, and searches a further "html_maxlines" lines back for a
synchronization point. These values can be configured using:

```
:let html_minlines = 500
:let html_maxlines = 750
```

HTML comments are rather special (see an HTML reference document for the
details), and the syntax coloring scheme will highlight all errors.
However, if you prefer to use the wrong style (starts with <!-- and
ends with -->) you can define

```
:let html_wrong_comments=1
```

JavaScript and Visual Basic embedded inside HTML documents are highlighted as
'Special' with statements, comments, strings and so on colored as in standard
programming languages. Note that only JavaScript and Visual Basic are
currently supported, no other scripting language has been added yet.

Embedded and inlined cascading style sheets (CSS) are highlighted too.

There are several html preprocessor languages out there. html.vim has been
written such that it should be trivial to include it. To do so add the
following two lines to the syntax coloring file for that language
(the example comes from the asp.vim file):

```
runtime! syntax/html.vim
syn cluster htmlPreproc add=asp
```

Now you just need to make sure that you add all regions that contain
the preprocessor language to the cluster htmlPreproc.

html-folding

The HTML syntax file provides syntax folding (see :syn-fold) between start
and end tags. This can be turned on by

```
:let g:html_syntax_folding = 1
:set foldmethod=syntax
```

Note: Syntax folding might slow down syntax highlighting significantly,
especially for large files.

HTML/OS (BY AESTIVA) ft-htmlos-syntax

The coloring scheme for HTML/OS works as follows:

Functions and variable names are the same color by default, because VIM
doesn't specify different colors for Functions and Identifiers. To change
this (which is recommended if you want function names to be recognizable in a
different color) you need to add the following line to your vimrc:

```
:hi Function cterm=bold ctermfg=LightGray
```

Of course, the ctermfg can be a different color if you choose.

Another issues that HTML/OS runs into is that there is no special filetype to
signify that it is a file with HTML/OS coding. You can change this by opening
a file and turning on HTML/OS syntax by doing the following:

```
:set syntax=htmlos
```

Lastly, it should be noted that the opening and closing characters to begin a
block of HTML/OS code can either be << or [[and >> or]], respectively.

IA64 **intel-itanium** **ft-ia64-syntax**

Highlighting for the Intel Itanium 64 assembly language. See ft-asm-syntax
for how to recognize this filetype.

To have *.inc files be recognized as IA64, add this to your vimrc file:

```
:let g:filetype_inc = "ia64"
```

ICALENDAR

ft-icalendar-syntax

Highlighting for iCalendar files (RFC 5545), as used by calendaring applications with an ".ics" extension.

Component boundaries (BEGIN: and END:), property names, property parameters and recurrence rule parts are highlighted separately. A content line may be split across several lines by inserting a line break followed by a space or a tab; such folded lines are highlighted as a single logical line.

Folding of components is provided by the filetype plugin and is off by default; see ft-icalendar-plugin.

INFORM

ft-inform-syntax

Inform highlighting includes symbols provided by the Inform Library, as most programs make extensive use of it. If do not wish Library symbols to be highlighted add this to your vim startup:

```
:let inform_highlight_simple=1
```

By default it is assumed that Inform programs are Z-machine targeted, and highlights Z-machine assembly language symbols appropriately. If you intend your program to be targeted to a Glulx/Glk environment you need to add this to your startup sequence:

```
:let inform_highlight_glulx=1
```

This will highlight Glulx opcodes instead, and also adds glk() to the set of highlighted system functions.

The Inform compiler will flag certain obsolete keywords as errors when it encounters them. These keywords are normally highlighted as errors by Vim. To prevent such error highlighting, you must add this to your startup sequence:

```
:let inform_suppress_obsolete=1
```

By default, the language features highlighted conform to Compiler version 6.30 and Library version 6.11. If you are using an older Inform development environment, you may with to add this to your startup sequence:

```
:let inform_highlight_old=1
```

IDL

idl-syntax

IDL (Interface Definition Language) files are used to define RPC calls. In Microsoft land, this is also used for defining COM interfaces and calls.

IDL's structure is simple enough to permit a full grammar based approach to rather than using a few heuristics. The result is large and somewhat repetitive but seems to work.

There are some Microsoft extensions to idl files that are here. Some of them are disabled by defining idl_no_ms_extensions.

The more complex of the extensions are disabled by defining idl_no_extensions.

Variable	Effect
idl_no_ms_extensions	Disable some of the Microsoft specific extensions
idl_no_extensions	Disable complex extensions
idlsyntax_showerror	Show IDL errors (can be rather intrusive, but quite helpful)
idlsyntax_showerror_soft	Use softer colours by default for errors

JAVA

ft-java-syntax

The java.vim syntax highlighting file offers several options.

In Java 1.0.2, it was never possible to have braces inside parens, so this was flagged as an error. Since Java 1.1, this is possible (with anonymous classes); and, therefore, is no longer marked as an error. If you prefer the old way, put the following line into your Vim startup file:

```
:let g:java_mark_braces_in_parens_as_errors = 1
```

All (exported) public types declared in java.lang are always automatically imported and available as simple names. To highlight them, use:

```
:let g:java_highlight_java_lang_ids = 1
```

You can also generate syntax items for other public and protected types and opt in to highlight some of their names; see java-package-info-url.

Headers of indented function declarations can be highlighted (along with parts
of lambda expressions and method reference expressions), but it depends on how
you write Java code. Two formats are recognized:

1) If you write function declarations that are consistently indented by either
a tab, or a space . . . or eight space character(s), you may want to set one
of

```
:let g:java_highlight_functions = "indent"
:let g:java_highlight_functions = "indent1"
:let g:java_highlight_functions = "indent2"
:let g:java_highlight_functions = "indent3"
:let g:java_highlight_functions = "indent4"
:let g:java_highlight_functions = "indent5"
:let g:java_highlight_functions = "indent6"
:let g:java_highlight_functions = "indent7"
:let g:java_highlight_functions = "indent8"
```

Note that in terms of 'shiftwidth', this is the leftmost step of indentation.

2) However, if you follow the Java guidelines about how functions and types
are supposed to be named (with respect to upper- and lowercase) and there is
any amount of indentation, you may want to set

```
:let g:java_highlight_functions = "style"
```

In addition, you can combine any value of "g:java_highlight_functions" with

```
:let g:java_highlight_signature = 1
```

to have the name of a function with its parameter list parens distinctly
highlighted from its type parameters, return type, and formal parameters; and
to have the parameter list parens of a lambda expression with its arrow
distinctly highlighted from its formal parameters or identifiers.

If neither setting does work for you, but you would still want headers of
function declarations to be highlighted, modify the current syntax definitions
or compose new ones.

Higher-order function types can be hard to parse by eye, so uniformly toning
down some of their components may be of value. Provided that such type names
conform to the Java naming guidelines, you may arrange it with

```
:let g:java_highlight_generics = 1
```

In Java 1.1, the functions System.out.println() and System.err.println()
should only be used for debugging. Consider adding the following definition
in your startup file:

```
:let g:java_highlight_debug = 1
```

to have the bulk of those statements colored as
        *Debug   debugging statements,
and to make some of their own items further grouped and linked:
        *Special   as DebugSpecial,
        *String   as DebugString,
        *Boolean   as DebugBoolean,
        *Type   as DebugType,
which are used for special characters appearing in strings, strings proper,
boolean literals, and special instance references (super, this, null),
respectively.

Javadoc is a program that takes special comments out of Java program files and
creates HTML pages. The standard configuration will highlight this HTML code
similarly to HTML files (see ft-html-syntax). You can even add JavaScript
and CSS inside this code (see below). The HTML rendering and the Markdown
rendering diverge as follows:
 1. The first sentence (all characters up to the first period ., which is

       followed by a whitespace character or a line terminator, or up to the
       first block tag, e.g. @param, @return) is colored as
          *SpecialComment   special comments.
 2. The text is colored as

          *Comment   comments.
 3. HTML comments are colored as

          *Special   special symbols.
 4. The standard Javadoc tags (@code, @see, etc.) are colored as

          *Special   special symbols
       and some of their arguments are colored as
          *Function   function names.

To turn this feature off for both HTML and Markdown, add the following line to your startup file:

```
:let g:java_ignore_javadoc = 1
```

Alternatively, only suppress HTML comments or Markdown comments:

```
:let g:java_ignore_html = 1
:let g:java_ignore_markdown = 1
```

See ft-java-plugin for additional support available for Markdown comments.

If you use the special Javadoc comment highlighting described above, you can also turn on special highlighting for JavaScript, Visual Basic scripts, and embedded CSS (stylesheets). This only makes sense if any of these languages actually appear in Javadoc comments. The variables to use are

```
:let g:java_javascript = 1
:let g:java_css = 1
:let g:java_vb = 1
```

Note that these three variables are maintained in the HTML syntax file.

Numbers and strings can be recognized in non-Javadoc comments with

```
:let g:java_comment_strings = 1
```

When 'foldmethod' is set to "syntax", multi-line blocks of code ("b"), plain comments ("c"), Javadoc comments ("d"), and adjacent "import" declarations ("i") will be folded by default. Syntax items of any supported kind will remain NOT foldable when its abbreviated name is delisted with

```
:let g:java_ignore_folding = "bcdi"
```

No text is usually written in the first line of a multi-line comment, making folded contents of Javadoc comments less informative with the default 'foldtext' value; you may opt for showing the contents of a second line for any comments written in this way, and showing the contents of a first line otherwise, with

```
:let g:java_foldtext_show_first_or_second_line = 1
```

HTML tags in Javadoc comments can additionally be folded by following the instructions listed under html-folding and giving explicit consent with

```
:let g:java_consent_to_html_syntax_folding = 1
```

Do not default to this kind of folding unless ALL start tags and optional end tags are balanced in Javadoc comments; otherwise, put up with creating runaway folds that break syntax highlighting.

Trailing whitespace characters or a run of space characters before a tab character can be marked as an error with

```
:let g:java_space_errors = 1
```

but either kind of an error can be suppressed by also defining one of

```
:let g:java_no_trail_space_error = 1
:let g:java_no_tab_space_error = 1
```

In order to highlight nested parens with different colors, define colors for javaParen, javaParen1, and javaParen2. For example,

```
:hi link javaParen Comment
```

or

```
:hi javaParen ctermfg=blue guifg=#0000ff
```

Certain modifiers are incompatible with each other, e.g. abstract and final:

```
:syn list javaConceptKind
```

and can be differently highlighted as a group than other modifiers with

```
:hi link javaConceptKind NonText
```

All instances of variable-width lookbehind assertions (/\@<! and /\@<=),
resorted to in syntax item definitions, are confined to arbitrary byte counts.
Another arbitrary value can be selected for a related group of definitions.
For example:

```
:let g:java_lookbehind_byte_counts = {'javaMarkdownCommentTitle': 240}
```

Where each key name of this dictionary is the name of a syntax item. The use
of these assertions in syntax items may vary among revisions, so no definitive
set of supported key names is committed to.

If you notice highlighting errors while scrolling backwards, which are fixed
when redrawing with CTRL-L, try setting the "g:java_minlines" variable to
a larger number:

```
:let g:java_minlines = 50
```

This will make the syntax synchronization start 50 lines before the first
displayed line. The default value is 10. The disadvantage of using a larger
number is that redrawing can become slow.

Significant changes to the Java platform are gradually introduced in the form
of JDK Enhancement Proposals (JEPs) that can be implemented for a release and
offered as its preview features. It may take several JEPs and a few release
cycles for such a feature to become either integrated into the platform or
withdrawn from this effort. To cater for early adopters, there is optional
support in Vim for syntax related preview features that are implemented. You
can request it by specifying a list of preview feature numbers as follows:

```
:let g:java_syntax_previews = [532]
```

The supported JEP numbers are to be drawn from this table:
        430: String Templates [JDK 21]
        532: Primitive types in Patterns, instanceof, and switch

Note that as soon as the particular preview feature will have been integrated
into the Java platform, its entry will be removed from the table and related
optionality will be discontinued.

java-package-info-url

https://github.com/zzzyxwvut/java-vim/blob/master/tools/javaid/src/javaid/package-info.java

JSON ft-json-syntax g:vim_json_conceal

g:vim_json_warnings

The json syntax file provides syntax highlighting with conceal support by
default. To disable concealment:

```
let g:vim_json_conceal = 0
```

To disable syntax highlighting of errors:

```
let g:vim_json_warnings = 0
```

JQ jq_quote_highlight ft-jq-syntax

To disable numbers having their own color add the following to your vimrc:

```
hi link jqNumber Normal
```

If you want quotes to have different highlighting than strings

```
let g:jq_quote_highlight = 1
```

KCONFIG ft-kconfig-syntax

Kconfig syntax highlighting language. For syntax syncing, you can configure
the following variable (default: 50):

```
let kconfig_minlines = 50
```

To configure a bit more (heavier) highlighting, set the following variable:

```
let kconfig_syntax_heavy = 1
```

LACE ft-lace-syntax

Lace (Language for Assembly of Classes in Eiffel) is case insensitive, but the
style guide lines are not. If you prefer case insensitive highlighting, just

define the vim variable 'lace_case_insensitive' in your startup file:

```
:let lace_case_insensitive=1
```

LF (LFRC)

ft-lf-syntax g:lf_shell_syntax

b:lf_shell_syntax

For the lf file manager configuration files (lfrc) the shell commands syntax
highlighting can be changed globally and per buffer by setting a different
'include' command search pattern using these variables:

```
let g:lf_shell_syntax = "syntax/dosbatch.vim"
let b:lf_shell_syntax = "syntax/zsh.vim"
```

These variables are unset by default.

The default 'include' command search pattern is 'syntax/sh.vim'.

LEX

ft-lex-syntax

Lex uses brute-force synchronizing as the "^%%$" section delimiter
gives no clue as to what section follows. Consequently, the value for

```
:syn sync minlines=300
```

may be changed by the user if they are experiencing synchronization
difficulties (such as may happen with large lex files).

LIFELINES

ft-lifelines-syntax

To highlight deprecated functions as errors, add in your vimrc:

```
:let g:lifelines_deprecated = 1
```

LISP

ft-lisp-syntax

The lisp syntax highlighting provides two options:

```
g:lisp_instring : If it exists, then "(...)" strings are highlighted
                  as if the contents of the string were lisp.
                  Useful for AutoLisp.
g:lisp_rainbow  : If it exists and is nonzero, then differing levels
                  of parenthesization will receive different
                  highlighting.
```

The g:lisp_rainbow option provides 10 levels of individual colorization for
the parentheses and backquoted parentheses. Because of the quantity of
colorization levels, unlike non-rainbow highlighting, the rainbow mode
specifies its highlighting using ctermfg and guifg, thereby bypassing the
usual color scheme control using standard highlighting groups. The actual
highlighting used depends on the dark/bright setting (see 'bg').

LITE

ft-lite-syntax

There are two options for the lite syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let lite_sql_query = 1
```

For syncing, minlines defaults to 100. If you prefer another value, you can
set "lite_minlines" to the value you desire. Example:

```
:let lite_minlines = 200
```

LOG

ft-log-syntax

Vim comes with a simplistic generic log syntax highlighter. Because the log
file format is so generic, highlighting is not enabled by default, since it
can be distracting. If you want to enable this, simply set the "log" filetype
manually:

```
:set ft=log
```

To enable this automatically for "*.log" files, add the following to your
personal filetype.vim file (usually located in ~/.config/nvim/filetype.vim
on Unix, see also new-filetype):

```
augroup filetypedetect
  au! BufNewFile,BufRead *.log  setfiletype log
augroup END
```

LPC

ft-lpc-syntax

LPC stands for a simple, memory-efficient language: Lars Pensjö C. The file name of LPC is usually *.c. Recognizing these files as LPC would bother users writing only C programs. If you want to use LPC syntax in Vim, you should set a variable in your vimrc file:

```
:let lpc_syntax_for_c = 1
```

If it doesn't work properly for some particular C or LPC files, use a modeline. For a LPC file:

```
// vim:set ft=lpc:
```

For a C file that is recognized as LPC:

```
// vim:set ft=c:
```

If you don't want to set the variable, use the modeline in EVERY LPC file.

There are several implementations for LPC, we intend to support most widely used ones. Here the default LPC syntax is for MudOS series, for MudOS v22 and before, you should turn off the sensible modifiers, and this will also assert the new efuns after v22 to be invalid, don't set this variable when you are using the latest version of MudOS:

```
:let lpc_pre_v22 = 1
```

For LpMud 3.2 series of LPC:

```
:let lpc_compat_32 = 1
```

For LPC4 series of LPC:

```
:let lpc_use_lpc4_syntax = 1
```

For uLPC series of LPC:
uLPC has been developed to Pike, so you should use Pike syntax instead, and the name of your source file should be *.pike

LUA

ft-lua-syntax

The Lua syntax file can be used for versions 4.0, 5.0+. You can select one of these versions using the global variables g:lua_version and g:lua_subversion.

MAIL

ft-mail.vim

Vim highlights all the standard elements of an email (headers, signatures, quoted text and URLs / email addresses). In keeping with standard conventions, signatures begin in a line containing only "--" followed optionally by whitespaces and end with a newline.

Vim treats lines beginning with "]", "}", "|", ">" or a word followed by ">" as quoted text. However Vim highlights headers and signatures in quoted text only if the text is quoted with ">" (optionally followed by one space).

By default mail.vim synchronises syntax to 100 lines before the first displayed line. If you have a slow machine, and generally deal with emails with short headers, you can change this to a smaller value:

```
:let mail_minlines = 30
```

MAKE

ft-make-syntax

In makefiles, commands are usually highlighted to make it easy for you to spot errors. However, this may be too much coloring for you. You can turn this feature off by using:

```
:let make_no_commands = 1
```

Comments are also highlighted by default. You can turn this off by using:

```
:let make_no_comments = 1
```

There are various Make implementations, which add extensions other than the POSIX specification and thus are mutually incompatible. If the filename is BSDmakefile or GNUmakefile, the corresponding implementation is automatically determined; otherwise vim tries to detect it by the file contents. If you see any wrong highlights because of this, you can enforce a flavor by setting one of the following:

```
:let g:make_flavor = 'bsd'  " or
:let g:make_flavor = 'gnu'  " or
:let g:make_flavor = 'microsoft'
```

MAPLE ft-maple-syntax

Maple V, by Waterloo Maple Inc, supports symbolic algebra. The language supports many packages of functions which are selectively loaded by the user. The standard set of packages' functions as supplied in Maple V release 4 may be highlighted at the user's discretion. Users may place in their vimrc file:

```
:let mvpkg_all= 1
```

to get all package functions highlighted, or users may select any subset by choosing a variable/package from the table below and setting that variable to 1, also in their vimrc file (prior to sourcing $VIMRUNTIME/syntax/syntax.vim).

Table of Maple V Package Function Selectors

```
mv_DEtools       mv_genfunc     mv_networks     mv_process
mv_Galois        mv_geometry    mv_numapprox    mv_simplex
mv_GaussInt      mv_grobner     mv_numtheory    mv_stats
mv_LREtools      mv_group       mv_orthopoly    mv_student
mv_combinat      mv_inttrans    mv_padic        mv_sumtools
mv_combstruct mv_liesymm        mv_plots        mv_tensor
mv_difforms      mv_linalg      mv_plottools    mv_totorder
mv_finance       mv_logic       mv_powseries
```

MARKDOWN ft-markdown-syntax g:markdown_minlines

g:markdown_fenced_languages g:markdown_syntax_conceal

If you have long regions there may be incorrect highlighting. At the cost of slowing down displaying, you can have the engine look further back to sync on the start of a region, for example 500 lines (default is 50):

```
:let g:markdown_minlines = 500
```

If you want to enable fenced code block syntax highlighting in your Markdown documents, set the following variable:

```
:let g:markdown_fenced_languages = ['html', 'python', 'bash=sh']
```

To disable Markdown syntax concealing, add the following to your vimrc:

```
:let g:markdown_syntax_conceal = 0
```

For extended Markdown support with enhanced features such as citations, footnotes, mathematical formulas, academic writing elements and embedded code block highlighting, consider using the pandoc syntax plugin. Set g:filetype_md to "pandoc" and see ft-pandoc-syntax for configuration details.

MATHEMATICA ft-mma-syntax ft-mathematica-syntax

Empty *.m files will automatically be presumed to be Matlab files unless you have the following in your vimrc:

```
let filetype_m = "mma"
```

MBSYNC ft-mbsync-syntax

The mbsync application uses a configuration file to setup mailboxes names, user and password. All files ending with .mbsyncrc or with the name isyncrc will be recognized as mbsync configuration files.

MEDIAWIKI ft-mediawiki-syntax

By default, syntax highlighting includes basic HTML tags like style and headers ft-html-syntax. For strict Mediawiki syntax highlighting:

```
let g:html_no_rendering = 1
```

If HTML highlighting is desired, terminal-based text formatting such as bold and italic is possible by:

```
let g:html_style_rendering = 1
```

MODULA2

ft-modula2-syntax

Vim will recognise comments with dialect tags to automatically select a given dialect.

The syntax for a dialect tag comment is:

```
taggedComment :=
  '(*!' dialectTag '*)'
  ;

dialectTag :=
  m2pim | m2iso | m2r10
  ;

reserved words
  m2pim = 'm2pim', m2iso = 'm2iso', m2r10 = 'm2r10'
```

A dialect tag comment is recognised by Vim if it occurs within the first 200 lines of the source file. Only the very first such comment is recognised, any additional dialect tag comments are ignored.

Example:

```
DEFINITION MODULE FooLib; (*!m2pim*)
...
```

Variable g:modula2_default_dialect sets the default Modula-2 dialect when the dialect cannot be determined from the contents of the Modula-2 file: if defined and set to 'm2pim', the default dialect is PIM.

Example:

```
let g:modula2_default_dialect = 'm2pim'
```

Highlighting is further configurable for each dialect via the following variables.

Variable	Highlight
modula2_iso_allow_lowline	allow low line in identifiers
modula2_iso_disallow_octals	disallow octal integer literals
modula2_iso_disallow_synonyms	disallow "@", "&" and "~" synonyms

```
modula2_pim_allow_lowline       allow low line in identifiers
modula2_pim_disallow_octals     disallow octal integer literals
modula2_pim_disallow_synonyms   disallow "&" and "~" synonyms

modula2_r10_allow_lowline       allow low line in identifiers
```

MOO

ft-moo-syntax

If you use C-style comments inside expressions and find it mangles your highlighting, you may want to use extended (slow!) matches for C-style comments:

```
:let moo_extended_cstyle_comments = 1
```

To disable highlighting of pronoun substitution patterns inside strings:

```
:let moo_no_pronoun_sub = 1
```

To disable highlighting of the regular expression operator "%|", and matching "%(" and "%)" inside strings:

```
:let moo_no_regexp = 1
```

Unmatched double quotes can be recognized and highlighted as errors:

```
:let moo_unmatched_quotes = 1
```

To highlight builtin properties (.name, .location, .programmer etc.):

```
:let moo_builtin_properties = 1
```

Unknown builtin functions can be recognized and highlighted as errors. If you use this option, add your own extensions to the mooKnownBuiltinFunction group. To enable this option:

```
:let moo_unknown_builtin_functions = 1
```

An example of adding sprintf() to the list of known builtin functions:

```
:syn keyword mooKnownBuiltinFunction sprintf contained
```

MSQL ft-msql-syntax

There are two options for the msql syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let msql_sql_query = 1
```

For syncing, minlines defaults to 100. If you prefer another value, you can set "msql_minlines" to the value you desire. Example:

```
:let msql_minlines = 200
```

NEOMUTT ft-neomuttrc-syntax

ft-neomuttlog-syntax

To disable the default NeoMutt log colors:

```
:let g:neolog_disable_default_colors = 1
```

N1QL ft-n1ql-syntax

N1QL is a SQL-like declarative language for manipulating JSON documents in Couchbase Server databases.

Vim syntax highlights N1QL statements, keywords, operators, types, comments, and special values. Vim ignores syntactical elements specific to SQL or its many dialects, like COLUMN or CHAR, that don't exist in N1QL.

NCF ft-ncf-syntax

There is one option for NCF syntax highlighting.

If you want to have unrecognized (by ncf.vim) statements highlighted as errors, use this:

```
:let ncf_highlight_unknowns = 1
```

If you don't want to highlight these errors, leave it unset.

NROFF ft-nroff-syntax

The nroff syntax file works with AT&T n/troff as-is. To support GNU troff (groff), which Linux and BSD distributions use as their default typesetting package, arrange for files to be recognized as groff input (see ft-groff-syntax) or add the following option to your start-up files:

```
:let nroff_is_groff = 1
```

GNU troff differs from older AT&T n/troff programs (that you may still find in Solaris or Plan 9) by extending the "*roff" language syntax. For example, in AT&T troff, you access the count of years since 1900 with the escape sequence \n(yr. In groff you can do the same, which it recognizes for compatibility, or use groff's extended syntax, \n[yr]. AT&T troff documented the yr register as storing the "last two digits of current year", but had a Y2K problem; in groff, you can access the Gregorian year correctly: \n[year]. In groff, font, register, macro, string, and request names can exceed two characters; for example, with groff's mm package, the control lines ".VERBON" and ".VERBOFF" call macros of those names to bracket displays of "verbatim" content.

In order to obtain the best formatted output g/troff can give you, you should follow a few simple rules about spacing and punctuation.

1. Break the line (put a carriage return) at the end of every sentence. Don't permit trailing spaces before the newline.
2. If a line ends with a period, question mark, or exclamation point that does not end a sentence, follow it with the dummy character escape sequence \&.
3. If you're using a macro package, employ its paragraphing macros to achieve indentation of paragraphs and spacing between them.
4. Use the empty request, a '.' on a line by itself, freely to visually separate material for ease of document maintenance.

The reason for these tips is that g/n/troff attempts to detect the ends of sentences, and can use that information to apply inter-sentence space. Using them also minimizes the size of diffs where lines change due only to refilling in the text editor. Macro packages typically employ inter-paragraph spacing amounts other than one vee (which is the result of a blank input line), and typically store that spacing amount, and that of paragraph indentation, in user-configurable registers so that pages lay out consistently.

Unlike TeX, troff fills text line-by-line, not paragraph-by-paragraph. If you desire consistent spacing between words and sentences in formatted output, you must maintain consistent spacing in the input text. To mark both trailing spaces and two or more spaces after a punctuation as an error, use:

```
:let nroff_space_errors = 1
```

Another technique to detect extra spacing and other errors that will interfere with the correct typesetting of your file, is to define an eye-catching highlighting definition for the syntax groups "nroffDefinition" and "nroffDefSpecial" in your configuration files. For example:

```
hi def nroffDefinition cterm=italic gui=reverse
hi def nroffDefSpecial cterm=italic,bold gui=reverse,bold
```

If you want to navigate preprocessor entries in your source file as easily as with section markers, you can activate the following option in your vimrc file:

```
let b:preprocs_as_sections = 1
```

Further, the syntax file adds an extra paragraph marker for the XP paragraphing macro in the ms package, a Berkeley and GNU extension.

Finally, there is a ft-groff-syntax file that can be used to enable groff syntax highlighting either on a per-file basis or globally by default.

OCAML **ft-ocaml-syntax**

The OCaml syntax file handles files having the following prefixes: .ml, .mli, .mll and .mly. By setting the following variable

```
:let ocaml_revised = 1
```

you can switch from standard OCaml-syntax to revised syntax as supported by the camlp4 preprocessor. Setting the variable

```
:let ocaml_noend_error = 1
```

prevents highlighting of "end" as error, which is useful when sources contain very long structures that Vim does not synchronize anymore.

PANDOC **ft-pandoc-syntax**

By default, markdown files will be detected as filetype "markdown". Alternatively, you may want them to be detected as filetype "pandoc" instead. To do so, set the g:filetype_md var:

```
:let g:filetype_md = 'pandoc'
```

The pandoc syntax plugin uses conceal for pretty highlighting. Default is 1

```
:let g:pandoc#syntax#conceal#use = 1
```

To specify elements that should not be concealed, set the following variable:

```
:let g:pandoc#syntax#conceal#blacklist = []
```

This is a list of the rules which can be used here:

- titleblock
- image
- block
- subscript
- superscript

- strikeout
- atx
- codeblock_start
- codeblock_delim
- footnote
- definition
- list
- newline
- dashes
- ellipses
- quotes
- inlinecode
- inlinemath

You can customize the way concealing works. For example, if you prefer to
mark footnotes with the * symbol:

```
:let g:pandoc#syntax#conceal#cchar_overrides = {"footnote" : "*"}
```

To conceal the urls in links, use:

```
:let g:pandoc#syntax#conceal#urls = 1
```

Prevent highlighting specific codeblock types so that they remain Normal.
Codeblock types include "definition" for codeblocks inside definition blocks
and "delimited" for delimited codeblocks. Default = []

```
:let g:pandoc#syntax#codeblocks#ignore = ['definition']
```

Use embedded highlighting for delimited codeblocks where a language is
specified. Default = 1

```
:let g:pandoc#syntax#codeblocks#embeds#use = 1
```

For specify what languages and using what syntax files to highlight embeds.
This is a list of language names. When the language pandoc and vim use don't
match, you can use the "PANDOC=VIM" syntax. For example:

```
:let g:pandoc#syntax#codeblocks#embeds#langs = ["ruby", "bash=sh"]
```

To use italics and strong in emphases. Default = 1

```
:let g:pandoc#syntax#style#emphases = 1
```

"0" will add "block" to g:pandoc#syntax#conceal#blacklist, because otherwise
you couldn't tell where the styles are applied.

To add underline subscript, superscript and strikeout text styles. Default = 1

```
:let g:pandoc#syntax#style#underline_special = 1
```

Detect and highlight definition lists. Disabling this can improve
performance. Default = 1 (i.e., enabled by default)

```
:let g:pandoc#syntax#style#use_definition_lists = 1
```

The pandoc syntax script also comes with the following commands:

```
:PandocHighlight LANG
```

Enables embedded highlighting for language LANG in codeblocks. Uses the
syntax for items in g:pandoc#syntax#codeblocks#embeds#langs.

```
:PandocUnhighlight LANG
```

Disables embedded highlighting for language LANG in codeblocks.

PAPP **ft-papp-syntax**

The PApp syntax file handles .papp files and, to a lesser extent, .pxml
and .pxsl files which are all a mixture of perl/xml/html/other using xml
as the top-level file format. By default everything inside phtml or pxml
sections is treated as a string with embedded preprocessor commands. If
you set the variable:

```
:let papp_include_html=1
```

in your startup file it will try to syntax-highlight html code inside phtml
sections, but this is relatively slow and much too colourful to be able to
edit sensibly. ;)

The newest version of the papp.vim syntax file can usually be found at
http://papp.plan9.de.

PASCAL **ft-pascal-syntax**

Files matching "*.p" could be Progress or Pascal and those matching "*.pp"
could be Puppet or Pascal. If the automatic detection doesn't work for you,
or you only edit Pascal files, use this in your startup vimrc:

```
:let filetype_p  = "pascal"
:let filetype_pp = "pascal"
```

The Pascal syntax file has been extended to take into account some extensions
provided by Turbo Pascal, Free Pascal Compiler and GNU Pascal Compiler.
Delphi keywords are also supported. By default, Turbo Pascal 7.0 features are
enabled. If you prefer to stick with the standard Pascal keywords, add the
following line to your startup file:

```
:let pascal_traditional=1
```

To switch on Delphi specific constructions (such as one-line comments,
keywords, etc):

```
:let pascal_delphi=1
```

The option pascal_symbol_operator controls whether symbol operators such as +,
*, .., etc. are displayed using the Operator color or not. To colorize symbol
operators, add the following line to your startup file:

```
:let pascal_symbol_operator=1
```

Some functions are highlighted by default. To switch it off:

```
:let pascal_no_functions=1
```

Furthermore, there are specific variables for some compilers. Besides
pascal_delphi, there are pascal_gpc and pascal_fpc. Default extensions try to
match Turbo Pascal.

```
:let pascal_gpc=1
```

or

```
:let pascal_fpc=1
```

To ensure that strings are defined on a single line, you can define the
pascal_one_line_string variable.

```
:let pascal_one_line_string=1
```

If you dislike <Tab> chars, you can set the pascal_no_tabs variable. Tabs
will be highlighted as Error.

```
:let pascal_no_tabs=1
```

PERL ft-perl-syntax

There are a number of possible options to the perl syntax highlighting.

Inline POD highlighting is now turned on by default. If you don't wish to have the added complexity of highlighting POD embedded within Perl files, you may set the 'perl_include_pod' option to 0:

```
:let perl_include_pod = 0
```

To reduce the complexity of parsing (and increase performance) you can switch off two elements in the parsing of variable names and contents.

To handle package references in variable and function names not differently from the rest of the name (like 'PkgName::' in '$PkgName::VarName'):

```
:let perl_no_scope_in_variables = 1
```

(In Vim 6.x it was the other way around: "perl_want_scope_in_variables" enabled it.)

If you do not want complex things like @{${"foo"}} to be parsed:

```
:let perl_no_extended_vars = 1
```

(In Vim 6.x it was the other way around: "perl_extended_vars" enabled it.)

The coloring strings can be changed. By default strings and qq friends will be highlighted like the first line. If you set the variable perl_string_as_statement, it will be highlighted as in the second line.

```
   "hello world!"; qq|hello world|;
   ^^^^^^^^^^^^^^NN^^^^^^^^^^^^^^^N       (unlet perl_string_as_statement)
   S^^^^^^^^^^^^SNNSSS^^^^^^^^^^^SN       (let perl_string_as_statement)
```

(^ = perlString, S = perlStatement, N = None at all)

The syncing has 3 options. The first two switch off some triggering of synchronization and should only be needed in case it fails to work properly. If while scrolling all of a sudden the whole screen changes color completely then you should try and switch off one of those. Let the developer know if you can figure out the line that causes the mistake.

One triggers on "^\s*sub\s*" and the other on "^[$@%]" more or less.

```
:let perl_no_sync_on_sub
:let perl_no_sync_on_global_var
```

Below you can set the maximum distance VIM should look for starting points for its attempts in syntax highlighting.

```
:let perl_sync_dist = 100
```

If you want to use folding with perl, set perl_fold:

```
:let perl_fold = 1
```

If you want to fold blocks in if statements, etc. as well set the following:

```
:let perl_fold_blocks = 1
```

Subroutines are folded by default if 'perl_fold' is set. If you do not want this, you can set 'perl_nofold_subs':

```
:let perl_nofold_subs = 1
```

Anonymous subroutines are not folded by default; you may enable their folding via 'perl_fold_anonymous_subs':

```
:let perl_fold_anonymous_subs = 1
```

Packages are also folded by default if 'perl_fold' is set. To disable this behavior, set 'perl_nofold_packages':

```
:let perl_nofold_packages = 1
```

PHP3 and PHP4 ft-php-syntax ft-php3-syntax

[**Note:** Previously this was called "php3", but since it now also supports php4 it has been renamed to "php"]

There are the following options for the php syntax highlighting.

If you like SQL syntax highlighting inside Strings:

```
let php_sql_query = 1
```

For highlighting the Baselib methods:

```
let php_baselib = 1
```

Enable HTML syntax highlighting inside strings:

```
let php_htmlInStrings = 1
```

Using the old colorstyle:

```
let php_oldStyle = 1
```

Enable highlighting ASP-style short tags:

```
let php_asp_tags = 1
```

Disable short tags:

```
let php_noShortTags = 1
```

For highlighting parent error] or):

```
let php_parent_error_close = 1
```

For skipping a php end tag, if there exists an open (or [without a closing
one:

```
let php_parent_error_open = 1
```

Enable folding for classes and functions:

```
let php_folding = 1
```

Selecting syncing method:

```
let php_sync_method = x
```

x = -1 to sync by search (default),
x > 0 to sync at least x lines backwards,
x = 0 to sync from start.

PLAINTEX ft-plaintex-syntax

TeX is a typesetting language, and plaintex is the file type for the "plain"
variant of TeX. If you never want your *.tex files recognized as plain TeX,
see ft-tex-plugin.

This syntax file has the option

```
let g:plaintex_delimiters = 1
```

if you want to highlight brackets "[]" and braces "{}".

PPWIZARD ft-ppwiz-syntax

PPWizard is a preprocessor for HTML and OS/2 INF files

This syntax file has the options:

- ppwiz_highlight_defs : Determines highlighting mode for PPWizard's

  definitions. Possible values are

  ppwiz_highlight_defs = 1 : PPWizard #define statements retain the
  colors of their contents (e.g. PPWizard macros and variables).

  ppwiz_highlight_defs = 2 : Preprocessor #define and #evaluate
  statements are shown in a single color with the exception of line
  continuation symbols.

  The default setting for ppwiz_highlight_defs is 1.

- ppwiz_with_html : If the value is 1 (the default), highlight literal

  HTML code; if 0, treat HTML code like ordinary text.

PHTML ft-phtml-syntax

There are two options for the phtml syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let phtml_sql_query = 1
```

For syncing, minlines defaults to 100. If you prefer another value, you can set "phtml_minlines" to the value you desire. Example:

```
:let phtml_minlines = 200
```

POSTSCRIPT ft-postscr-syntax

There are several options when it comes to highlighting PostScript.

First which version of the PostScript language to highlight. There are currently three defined language versions, or levels. Level 1 is the original and base version, and includes all extensions prior to the release of level 2. Level 2 is the most common version around, and includes its own set of extensions prior to the release of level 3. Level 3 is currently the highest level supported. You select which level of the PostScript language you want highlighted by defining the postscr_level variable as follows:

```
:let postscr_level=2
```

If this variable is not defined it defaults to 2 (level 2) since this is the most prevalent version currently.

Note: Not all PS interpreters will support all language features for a particular language level. In particular the %!PS-Adobe-3.0 at the start of PS files does NOT mean the PostScript present is level 3 PostScript!

If you are working with Display PostScript, you can include highlighting of Display PS language features by defining the postscr_display variable as follows:

```
:let postscr_display=1
```

If you are working with Ghostscript, you can include highlighting of Ghostscript specific language features by defining the variable postscr_ghostscript as follows:

```
:let postscr_ghostscript=1
```

PostScript is a large language, with many predefined elements. While it useful to have all these elements highlighted, on slower machines this can cause Vim to slow down. In an attempt to be machine friendly font names and character encodings are not highlighted by default. Unless you are working explicitly with either of these this should be ok. If you want them to be highlighted you should set one or both of the following variables:

```
:let postscr_fonts=1
:let postscr_encodings=1
```

There is a stylistic option to the highlighting of and, or, and not. In PostScript the function of these operators depends on the types of their operands - if the operands are booleans then they are the logical operators, if they are integers then they are binary operators. As binary and logical operators can be highlighted differently they have to be highlighted one way or the other. By default they are treated as logical operators. They can be highlighted as binary operators by defining the variable postscr_andornot_binary as follows:

```
:let postscr_andornot_binary=1
```

ft-printcap-syntax

PRINTCAP + TERMCAP ft-ptcap-syntax ft-termcap-syntax

This syntax file applies to the printcap and termcap databases.

In order for Vim to recognize printcap/termcap files that do not match the patterns "*printcap*", or "*termcap*", you must put additional patterns appropriate to your system in your myfiletypefile file. For these patterns, you must set the variable "b:ptcap_type" to either "print" or "term", and then the 'filetype' option to ptcap.

For example, to make Vim identify all files in /etc/termcaps/ as termcap files, add the following:

```
:au BufNewFile,BufRead /etc/termcaps/* let b:ptcap_type = "term" |
                                    \ set filetype=ptcap
```

If you notice highlighting errors while scrolling backwards, which

are fixed when redrawing with CTRL-L, try setting the "ptcap_minlines"
internal variable to a larger number:

```
:let ptcap_minlines = 50
```

(The default is 20 lines.)

PROGRESS ft-progress-syntax

Files matching "*.w" could be Progress or cweb. If the automatic detection
doesn't work for you, or you don't edit cweb at all, use this in your
startup vimrc:

```
:let filetype_w = "progress"
```

The same happens for "*.i", which could be assembly, and "*.p", which could be
Pascal. Use this if you don't use assembly and Pascal:

```
:let filetype_i = "progress"
:let filetype_p = "progress"
```

PYTHON ft-python-syntax

There are seven options to control Python syntax highlighting.

For highlighted numbers:

```
:let python_no_number_highlight = 1
```

For highlighted builtin functions:

```
:let python_no_builtin_highlight = 1
```

For highlighted standard exceptions:

```
:let python_no_exception_highlight = 1
```

For highlighted doctests and code inside:

```
:let python_no_doctest_highlight = 1
```

or

```
:let python_no_doctest_code_highlight = 1
```

The first option implies the second one.

For highlighted trailing whitespace and mix of spaces and tabs:

```
:let python_space_error_highlight = 1
```

For highlighted built-in constants distinguished from other keywords:

```
:let python_constant_highlight = 1
```

If you want all possible Python highlighting:

```
:let python_highlight_all = 1
```

This has the same effect as setting python_space_error_highlight,
python_constant_highlight and unsetting all the other ones.

If you use Python 2 or straddling code (Python 2 and 3 compatible),
you can enforce the use of an older syntax file with support for
Python 2 and up to Python 3.5.

```
:let python_use_python2_syntax = 1
```

This option will exclude all modern Python 3.6 or higher features.

Note: Only existence of these options matters, not their value.
You can replace 1 above with anything.

QUAKE ft-quake-syntax

The Quake syntax definition should work for most FPS (First Person Shooter)
based on one of the Quake engines. However, the command names vary a bit
between the three games (Quake, Quake 2, and Quake 3 Arena) so the syntax
definition checks for the existence of three global variables to allow users

to specify what commands are legal in their files. The three variables can
be set for the following effects:

set to highlight commands only available in Quake:

```
:let quake_is_quake1 = 1
```

set to highlight commands only available in Quake 2:

```
:let quake_is_quake2 = 1
```

set to highlight commands only available in Quake 3 Arena:

```
:let quake_is_quake3 = 1
```

Any combination of these three variables is legal, but might highlight more
commands than are actually available to you by the game.

R ft-r-syntax

The parsing of R code for syntax highlight starts 40 lines backwards, but you
can set a different value in your vimrc. Example:

```
let r_syntax_minlines = 60
```

You can also turn off syntax highlighting of ROxygen:

```
let r_syntax_hl_roxygen = 0
```

enable folding of code delimited by parentheses, square brackets and curly
braces:

```
let r_syntax_folding = 1
```

and highlight as functions all keywords followed by an opening parenthesis:

```
let r_syntax_fun_pattern = 1
```

R MARKDOWN ft-rmd-syntax

To disable syntax highlight of YAML header, add to your vimrc:

```
let rmd_syn_hl_yaml = 0
```

To disable syntax highlighting of citation keys:

```
let rmd_syn_hl_citations = 0
```

To highlight R code in knitr chunk headers:

```
let rmd_syn_hl_chunk = 1
```

By default, chunks of R code will be highlighted following the rules of R
language. Moreover, whenever the buffer is saved, Vim scans the buffer and
highlights other languages if they are present in new chunks. LaTeX code also
is automatically recognized and highlighted when the buffer is saved. This
behavior can be controlled with the variables rmd_dynamic_fenced_languages,
and rmd_include_latex whose valid values are:

```
let rmd_dynamic_fenced_languages = 0 " No autodetection of languages
let rmd_dynamic_fenced_languages = 1 " Autodetection of languages
let rmd_include_latex = 0 " Don't highlight LaTeX code
let rmd_include_latex = 1 " Autodetect LaTeX code
let rmd_include_latex = 2 " Always include LaTeX highlighting
```

If the value of rmd_dynamic_fenced_languages is 0, you still can set the
list of languages whose chunks of code should be properly highlighted, as in
the example:

```
let rmd_fenced_languages = ['r', 'python']
```

R RESTRUCTURED TEXT ft-rrst-syntax

To highlight R code in knitr chunk headers, add to your vimrc:

```
let rrst_syn_hl_chunk = 1
```

RASI ft-rasi-syntax

Rasi stands for Rofi Advanced Style Information. It is used by the program rofi to style the rendering of the search window. The language is heavily inspired by CSS stylesheet. Files with the following extensions are recognized as rasi files: .rasi.

READLINE ft-readline-syntax

The readline library is primarily used by the BASH shell, which adds quite a few commands and options to the ones already available. To highlight these items as well you can add the following to your vimrc or just type it in the command line before loading a file with the readline syntax:

```
let readline_has_bash = 1
```

This will add highlighting for the commands that BASH (version 2.05a and later, and part earlier) adds.

REGO ft-rego-syntax

Rego is a query language developed by Styra. It is mostly used as a policy language for kubernetes, but can be applied to almost anything. Files with the following extensions are recognized as rego files: .rego.

RESTRUCTURED TEXT ft-rst-syntax

Syntax highlighting is enabled for code blocks within the document for a select number of file types. See $VIMRUNTIME/syntax/rst.vim for the default syntax list.

To set a user-defined list of code block syntax highlighting:

```
let rst_syntax_code_list = ['vim', 'lisp', ...]
```

To assign multiple code block types to a single syntax, define rst_syntax_code_list as a mapping:

```
let rst_syntax_code_list = {
        \ 'cpp': ['cpp', 'c++'],
        \ 'bash': ['bash', 'sh'],
        ...
\ }
```

To use color highlighting for emphasis text:

```
let rst_use_emphasis_colors = 1
```

To enable folding of sections:

```
let rst_fold_enabled = 1
```

Note that folding can cause performance issues on some platforms.

The minimum line syntax sync is set to 50. To modify this number:

```
let rst_minlines = 100
```

REXX ft-rexx-syntax

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with CTRL-L, try setting the "rexx_minlines" internal variable to a larger number:

```
:let rexx_minlines = 50
```

This will make the syntax synchronization start 50 lines before the first displayed line. The default value is 10. The disadvantage of using a larger number is that redrawing can become slow.

Vim tries to guess what type a ".r" file is. If it can't be detected (from comment lines), the default is "r". To make the default rexx add this line to your vimrc: g:filetype_r

```
:let g:filetype_r = "r"
```

RUBY ft-ruby-syntax

Ruby: Operator highlighting	ruby_operators
Ruby: Whitespace errors	ruby_space_errors
Ruby: Folding	ruby_fold ruby_foldable_groups

    Ruby: Reducing expensive operations ruby_no_expensive ruby_minlines
    Ruby: Spellchecking strings   ruby_spellcheck_strings

ruby_operators

Ruby: Operator highlighting

Operators can be highlighted by defining "ruby_operators":

```
:let ruby_operators = 1
```

ruby_space_errors

Ruby: Whitespace errors

Whitespace errors can be highlighted by defining "ruby_space_errors":

```
:let ruby_space_errors = 1
```

This will highlight trailing whitespace and tabs preceded by a space character as errors. This can be refined by defining "ruby_no_trail_space_error" and "ruby_no_tab_space_error" which will ignore trailing whitespace and tabs after spaces respectively.

ruby_fold ruby_foldable_groups

Ruby: Folding

Folding can be enabled by defining "ruby_fold":

```
:let ruby_fold = 1
```

This will set the value of 'foldmethod' to "syntax" locally to the current buffer or window, which will enable syntax-based folding when editing Ruby filetypes.

Default folding is rather detailed, i.e., small syntax units like "if", "do", "%w[]" may create corresponding fold levels.

You can set "ruby_foldable_groups" to restrict which groups are foldable:

```
:let ruby_foldable_groups = 'if case %'
```

The value is a space-separated list of keywords:

keyword	meaning
ALL	Most block syntax (default)
NONE	Nothing
if	"if" or "unless" block
def	"def" block
class	"class" block
module	"module" block
do	"do" block
begin	"begin" block
case	"case" block
for	"for", "while", "until" loops
{	Curly bracket block or hash literal
[	Array literal
%	Literal with "%" notation, e.g.: %w(STRING), %!STRING!
/	Regexp
string	String and shell command output (surrounded by ', ", "`")
:	Symbol
#	Multiline comment
<<	Here documents
__END__	Source code after "__END__" directive

ruby_no_expensive

Ruby: Reducing expensive operations

By default, the "end" keyword is colorized according to the opening statement of the block it closes. While useful, this feature can be expensive; if you experience slow redrawing (or you are on a terminal with poor color support) you may want to turn it off by defining the "ruby_no_expensive" variable:

```
:let ruby_no_expensive = 1
```

In this case the same color will be used for all control keywords.

ruby_minlines

If you do want this feature enabled, but notice highlighting errors while scrolling backwards, which are fixed when redrawing with CTRL-L, try setting the "ruby_minlines" variable to a value larger than 50:

```
:let ruby_minlines = 100
```

Ideally, this value should be a number of lines large enough to embrace your largest class or module.

ruby_spellcheck_strings

Ruby: Spellchecking strings

Ruby syntax will perform spellchecking of strings if you define "ruby_spellcheck_strings":

```
:let ruby_spellcheck_strings = 1
```

SCHEME ft-scheme-syntax

By default only R7RS keywords are highlighted and properly indented.

scheme.vim also supports extensions of the CHICKEN Scheme->C compiler.
Define b:is_chicken or g:is_chicken, if you need them.

SDL ft-sdl-syntax

The SDL highlighting probably misses a few keywords, but SDL has so many
of them it's almost impossibly to cope.

The new standard, SDL-2000, specifies that all identifiers are
case-sensitive (which was not so before), and that all keywords can be
used either completely lowercase or completely uppercase. To have the
highlighting reflect this, you can set the following variable:

```
:let sdl_2000=1
```

This also sets many new keywords. If you want to disable the old
keywords, which is probably a good idea, use:

```
:let SDL_no_96=1
```

The indentation is probably also incomplete, but right now I am very
satisfied with it for my own projects.

SED ft-sed-syntax

To make tabs stand out from regular blanks (accomplished by using Todo
highlighting on the tabs), define "g:sed_highlight_tabs" by putting

```
:let g:sed_highlight_tabs = 1
```

in the vimrc file. (This special highlighting only applies for tabs
inside search patterns, replacement texts, addresses or text included
by an Append/Change/Insert command.) If you enable this option, it is
also a good idea to set the tab width to one character; by doing that,
you can easily count the number of tabs in a string.

GNU sed allows comments after text on the same line. BSD sed only allows
comments where "#" is the first character of the line. To enforce BSD-style
comments, i.e. mark end-of-line comments as errors, use:

```
:let g:sed_dialect = "bsd"
```

Note that there are other differences between GNU sed and BSD sed which are
not (yet) affected by this setting.

Bugs:

  The transform command (y) is treated exactly like the substitute
  command. This means that, as far as this syntax file is concerned,
  transform accepts the same flags as substitute, which is wrong.
  (Transform accepts no flags.) I tolerate this bug because the
  involved commands need very complex treatment (95 patterns, one for
  each plausible pattern delimiter).

SGML ft-sgml-syntax

The coloring scheme for tags in the SGML file works as follows.

The <> of opening tags are colored differently than the </> of a closing tag.
This is on purpose! For opening tags the 'Function' color is used, while for
closing tags the 'Type' color is used (See syntax.vim to check how those are
defined for you)

Known tag names are colored the same way as statements in C. Unknown tag
names are not colored which makes it easy to spot errors.

Note that the same is true for argument (or attribute) names. Known attribute
names are colored differently than unknown ones.

Some SGML tags are used to change the rendering of text. The following tags
are recognized by the sgml.vim syntax coloring file and change the way normal
text is shown: <varname> <emphasis> <command> <function> <literal>
<replaceable> <ulink> and <link>.

If you want to change how such text is rendered, you must redefine the
following syntax groups:

- sgmlBold
- sgmlBoldItalic
- sgmlUnderline
- sgmlItalic

- sgmlLink for links

To make this redefinition work you must redefine them all and define the
following variable in your vimrc (this is due to the order in which the files
are read during initialization)

```
let sgml_my_rendering=1
```

You can also disable this rendering by adding the following line to your
vimrc file:

```
let sgml_no_rendering=1
```

(Adapted from the html.vim help text by Claudio Fleiner <claudio@fleiner.com>)

ft-posix-syntax ft-dash-syntax

SH ft-sh-syntax ft-bash-syntax ft-ksh-syntax

This covers syntax highlighting for the older Unix (Bourne) sh, and newer
shells such as bash, dash, posix, and the Korn shells.

Vim attempts to determine which shell type is in use by specifying that
various filenames are of specific types, e.g.:

```
ksh : .kshrc* *.ksh
bash: .bashrc* bashrc bash.bashrc .bash_profile* *.bash
```

See $VIMRUNTIME/filetype.vim for the full list of patterns. If none of these
cases pertain, then the first line of the file is examined (ex. looking for
/bin/sh /bin/ksh /bin/bash). If the first line specifies a shelltype, then
that shelltype is used. However some files (ex. .profile) are known to be
shell files but the type is not apparent. Furthermore, on many systems sh is
symbolically linked to "bash" (Linux, Windows+cygwin) or "ksh" (POSIX).

One may specify a global default by instantiating one of the following
variables in your vimrc:

   ksh:

```
let g:is_kornshell = 1
```

   posix: (default)

```
let g:is_posix     = 1
```

   bash:

```
let g:is_bash      = 1
```

   dash:

```
let g:is_dash      = 1
```

   sh: Bourne shell

```
let g:is_sh        = 1
```

Specific shell features are automatically enabled based on the shell detected
from the shebang line ("#! ...""). For KornShell Vim detects different shell
features for mksh, ksh88, ksh93, ksh93u, ksh93v, and ksh2020.

If there's no "#! ..." line, and the user hasn't availed themself of a default
sh.vim syntax setting as just shown, then syntax/sh.vim will assume the POSIX
shell syntax. No need to quote RFCs or market penetration statistics in error
reports, please -- just select the default version of the sh your system uses
and install the associated "let..." in your <.vimrc>.

The syntax/sh.vim file provides several levels of syntax-based folding:

```
let g:sh_fold_enabled= 0     (default, no syntax folding)
let g:sh_fold_enabled= 1     (enable function folding)
let g:sh_fold_enabled= 2     (enable heredoc folding)
let g:sh_fold_enabled= 4     (enable if/do/for folding)
```

then various syntax items (ie. HereDocuments and function bodies) become
syntax-foldable (see :syn-fold). You also may add these together
to get multiple types of folding:

```
let g:sh_fold_enabled= 3     (enables function and heredoc folding)
```

If you notice highlighting errors while scrolling backwards which are fixed
when one redraws with CTRL-L, try setting the "sh_minlines" internal variable
to a larger number. Example:

```
let sh_minlines = 500
```

This will make syntax synchronization start 500 lines before the first
displayed line. The default value is 200. The disadvantage of using a larger
number is that redrawing can become slow.

If you don't have much to synchronize on, displaying can be very slow. To
reduce this, the "sh_maxlines" internal variable can be set. Example:

```
let sh_maxlines = 100
```

The default is to use the twice sh_minlines. Set it to a smaller number to
speed up displaying. The disadvantage is that highlight errors may appear.

Unmatched "]", "done", "fi", etc., are highlighted as errors by default. If
you find this error handling problematic, you may suppress it with:

```
let g:sh_no_error = 1
```

As a refinement, you may suppress particular classes of errors by looking up
their syntax rule names and listing them with:

```
let g:sh_no_error_rules = ["shCurlyError", "shParenError"]
```

sh-embed sh-awk

Sh: EMBEDDING LANGUAGES~

You may wish to embed languages into sh. I'll give an example courtesy of
Lorance Stinson on how to do this with awk as an example. Put the following
file into $HOME/.config/nvim/after/syntax/sh/awkembed.vim:

```
" AWK Embedding:
" ==============
" Shamelessly ripped from aspperl.vim by Aaron Hope.
if exists("b:current_syntax")
  unlet b:current_syntax
endif
syn include @AWKScript syntax/awk.vim
syn region AWKScriptCode matchgroup=AWKCommand start=+[=\\]\@<!'+ skip=+\\'+ end=+'+ contains=@AWKScript contained
syn region AWKScriptEmbedded matchgroup=AWKCommand start=+\<awk\>+ skip=+\\$+ end=+[=\\]\@<!'+me=e-1 contains=@shIdList,@shExprList2
nextgroup=AWKScriptCode
syn cluster shCommandSubList add=AWKScriptEmbedded
hi def link AWKCommand Type
```

This code will then let the awk code in the single quotes:

```
awk '...awk code here...'
```

be highlighted using the awk highlighting syntax. Clearly this may be
extended to other languages.

SPEEDUP **ft-spup-syntax**

(AspenTech plant simulator)

The Speedup syntax file has some options:

- strict_subsections : If this variable is defined, only keywords for

  sections and subsections will be highlighted as statements but not
  other keywords (like WITHIN in the OPERATION section).
- highlight_types : Definition of this variable causes stream types

  like temperature or pressure to be highlighted as Type, not as a
  plain Identifier. Included are the types that are usually found in
  the DECLARE section; if you defined own types, you have to include
  them in the syntax file.
- oneline_comments : This value ranges from 1 to 3 and determines the

  highlighting of # style comments.

  oneline_comments = 1 : Allow normal Speedup code after an even
  number of #s.

  oneline_comments = 2 : Show code starting with the second # as
  error. This is the default setting.

  oneline_comments = 3 : Show the whole line as error if it contains
  more than one #.

Since especially OPERATION sections tend to become very large due to
PRESETting variables, syncing may be critical. If your computer is
fast enough, you can increase minlines and/or maxlines near the end of
the syntax file.

SQL **ft-sql-syntax**

ft-sqlinformix-syntax

ft-sqlanywhere-syntax

While there is an ANSI standard for SQL, most database engines add their own
custom extensions. Vim currently supports the Oracle and Informix dialects of

SQL. Vim assumes "*.sql" files are Oracle SQL by default.

Vim currently has SQL support for a variety of different vendors via syntax scripts. You can change Vim's default from Oracle to any of the current SQL supported types. You can also easily alter the SQL dialect being used on a buffer by buffer basis.

For more detailed instructions see ft_sql.txt.

SQUIRREL **ft-squirrel-syntax**

Squirrel is a high level imperative, object-oriented programming language, designed to be a light-weight scripting language that fits in the size, memory bandwidth, and real-time requirements of applications like video games. Files with the following extensions are recognized as squirrel files: .nut.

TCSH **ft-tcsh-syntax**

This covers the shell named "tcsh". It is a superset of csh. See ft-csh-syntax for how the filetype is detected.

Tcsh does not allow \" in strings unless the "backslash_quote" shell variable is set. If you want VIM to assume that no backslash quote constructs exist add this line to your vimrc:

```
:let tcsh_backslash_quote = 0
```

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with CTRL-L, try setting the "tcsh_minlines" internal variable to a larger number:

```
:let tcsh_minlines = 1000
```

This will make the syntax synchronization start 1000 lines before the first displayed line. If you set "tcsh_minlines" to "fromstart", then synchronization is done from the start of the file. The default value for tcsh_minlines is 100. The disadvantage of using a larger number is that redrawing can become slow.

TEX **ft-tex-syntax** **latex-syntax**

syntax-tex syntax-latex

Tex Contents~

Tex: Want Syntax Folding? tex-folding

tex-folding g:tex_fold_enabled

Tex: Want Syntax Folding?

As of version 28 of <syntax/tex.vim>, syntax-based folding of parts, chapters, sections, subsections, etc are supported. Put

```
let g:tex_fold_enabled=1
```

in your vimrc, and :set fdm=syntax. I suggest doing the latter via a modeline at the end of your LaTeX file:

```
% vim: fdm=syntax
```

If your system becomes too slow, then you might wish to look into

```
https://vimhelp.org/vim_faq.txt.html#faq-29.7
```

g:tex_nospell

Tex: No Spell Checking Wanted~

If you don't want spell checking anywhere in your LaTeX document, put

```
let g:tex_nospell=1
```

into your vimrc. If you merely wish to suppress spell checking inside comments only, see g:tex_comment_nospell.

tex-nospell g:tex_comment_nospell

Tex: Don't Want Spell Checking In Comments?

Some folks like to include things like source code in comments and so would
prefer that spell checking be disabled in comments in LaTeX files. To do
this, put the following in your vimrc:

```
let g:tex_comment_nospell= 1
```

If you want to suppress spell checking everywhere inside your LaTeX document,
see g:tex_nospell.

tex-verb g:tex_verbspell

Tex: Want Spell Checking in Verbatim Zones?~

Often verbatim regions are used for things like source code; seldom does
one want source code spell-checked. However, for those of you who do
want your verbatim zones spell-checked, put the following in your vimrc:

```
let g:tex_verbspell= 1
```

tex-runon tex-stopzone

Tex: Run-on Comments or MathZones

The <syntax/tex.vim> highlighting supports TeX, LaTeX, and some AmsTeX. The
highlighting supports three primary zones/regions: normal, texZone, and
texMathZone. Although considerable effort has been made to have these zones
terminate properly, zones delineated by $..$ and $$..$$ cannot be synchronized
as there's no difference between start and end patterns. Consequently, a
special "TeX comment" has been provided

```
%stopzone
```

which will forcibly terminate the highlighting of either a texZone or a
texMathZone.

tex-slow tex-sync

Tex: Slow Syntax Highlighting?

If you have a slow computer, you may wish to reduce the values for

```
:syn sync maxlines=200
:syn sync minlines=50
```

(especially the latter). If your computer is fast, you may wish to
increase them. This primarily affects synchronizing (i.e. just what group,
if any, is the text at the top of the screen supposed to be in?).

Another cause of slow highlighting is due to syntax-driven folding; see
tex-folding for a way around this.

g:tex_fast

Finally, if syntax highlighting is still too slow, you may set

```
:let g:tex_fast= ""
```

in your vimrc. Used this way, the g:tex_fast variable causes the syntax
highlighting script to avoid defining any regions and associated
synchronization. The result will be much faster syntax highlighting; the
price: you will no longer have as much highlighting or any syntax-based
folding, and you will be missing syntax-based error checking.

You may decide that some syntax is acceptable; you may use the following table
selectively to enable just some syntax highlighting:

```
b : allow bold and italic syntax
c : allow texComment syntax
m : allow texMatcher syntax (ie. {...} and [...])
M : allow texMath syntax
p : allow parts, chapter, section, etc syntax
r : allow texRefZone syntax (nocite, bibliography, label, pageref, eqref)
s : allow superscript/subscript regions
S : allow texStyle syntax
v : allow verbatim syntax
V : allow texNewEnv and texNewCmd syntax
```

As an example, let g:tex_fast= "M" will allow math-associated highlighting
but suppress all the other region-based syntax highlighting.
(also see: g:tex_conceal and tex-supersub)

tex-morecommands tex-package

Tex: Want To Highlight More Commands?

LaTeX is a programmable language, and so there are thousands of packages full
of specialized LaTeX commands, syntax, and fonts. If you're using such a
package you'll often wish that the distributed syntax/tex.vim would support
it. However, clearly this is impractical. So please consider using the
techniques in mysyntaxfile-add to extend or modify the highlighting provided
by syntax/tex.vim.

I've included some support for various popular packages on my website:

```
https://www.drchip.org/astronaut/vim/index.html#LATEXPKGS
```

The syntax files there go into your .../after/syntax/tex/ directory.

tex-error g:tex_no_error

Tex: Excessive Error Highlighting?

The <tex.vim> supports lexical error checking of various sorts. Thus, although the error checking is ofttimes very useful, it can indicate errors where none actually are. If this proves to be a problem for you, you may put in your vimrc the following statement:

```
let g:tex_no_error=1
```

and all error checking by <syntax/tex.vim> will be suppressed.

tex-math

Tex: Need a new Math Group?

If you want to include a new math group in your LaTeX, the following code shows you an example as to how you might do so:

```
call TexNewMathZone(sfx,mathzone,starform)
```

You'll want to provide the new math group with a unique suffix (currently, A-L and V-Z are taken by <syntax/tex.vim> itself). As an example, consider how eqnarray is set up by <syntax/tex.vim>:

```
call TexNewMathZone("D","eqnarray",1)
```

You'll need to change "mathzone" to the name of your new math group, and then to the call to it in .vim/after/syntax/tex.vim. The "starform" variable, if true, implies that your new math group has a starred form (ie. eqnarray*).

tex-style b:tex_stylish

Tex: Starting a New Style?

One may use "\makeatletter" in *.tex files, thereby making the use of "@" in commands available. However, since the *.tex file doesn't have one of the following suffices: sty cls clo dtx ltx, the syntax highlighting will flag such use of @ as an error. To solve this:

```
:let b:tex_stylish = 1
:set ft=tex
```

Putting "let g:tex_stylish=1" into your vimrc will make <syntax/tex.vim> always accept such use of @.

tex-cchar tex-cole tex-conceal

Tex: Taking Advantage of Conceal Mode~

If you have 'conceallevel' set to 2 and if your encoding is utf-8, then a number of character sequences can be translated into appropriate utf-8 glyphs, including various accented characters, Greek characters in MathZones, and superscripts and subscripts in MathZones. Not all characters can be made into superscripts or subscripts; the constraint is due to what utf-8 supports. In fact, only a few characters are supported as subscripts.

One way to use this is to have vertically split windows (see CTRL-W_v); one with 'conceallevel' at 0 and the other at 2; and both using 'scrollbind'.

g:tex_conceal

Tex: Selective Conceal Mode~

You may selectively use conceal mode by setting g:tex_conceal in your vimrc. By default, g:tex_conceal is set to "admgs" to enable concealment for the following sets of characters:

```
a = accents/ligatures
b = bold and italic
d = delimiters
m = math symbols
g = Greek
s = superscripts/subscripts
```

By leaving one or more of these out, the associated conceal-character substitution will not be made.

g:tex_isk g:tex_stylish

Tex: Controlling iskeyword~

Normally, LaTeX keywords support 0-9, a-z, A-z, and 192-255 only. Latex keywords don't support the underscore - except when in *.sty files. The syntax highlighting script handles this with the following logic:

```
        * If g:tex_stylish exists and is 1
                then the file will be treated as a "sty" file, so the "_"
                will be allowed as part of keywords
                (regardless of g:tex_isk)
        * Else if the file's suffix is sty, cls, clo, dtx, or ltx,
                then the file will be treated as a "sty" file, so the "_"
                will be allowed as part of keywords
                (regardless of g:tex_isk)
```

* If g:tex_isk exists, then it will be used for the local 'iskeyword'
* Else the local 'iskeyword' will be set to 48-57,a-z,A-Z,192-255

tex-supersub g:tex_superscripts g:tex_subscripts

Tex: Fine Subscript and Superscript Control~

See tex-conceal for how to enable concealed character replacement.

See g:tex_conceal for selectively concealing accents, bold/italic, math, Greek, and superscripts/subscripts.

One may exert fine control over which superscripts and subscripts one wants syntax-based concealment for (see :syn-cchar). Since not all fonts support all characters, one may override the concealed-replacement lists; by default these lists are given by:

```
let g:tex_superscripts= "[0-9a-zA-W.,:;+-<>/()=]"
let g:tex_subscripts= "[0-9aehijklmnoprstuvx,+-/().]"
```

For example, I use Luxi Mono Bold; it doesn't support subscript characters for "hklmnpst", so I put

```
let g:tex_subscripts= "[0-9aeijoruvx,+-/().]"
```

in ~/.config/nvim/ftplugin/tex/tex.vim in order to avoid having inscrutable utf-8 glyphs appear.

tex-matchcheck g:tex_matchcheck

Tex: Match Check Control~

Sometimes one actually wants mismatched parentheses, square braces, and or curly braces; for example, \text{(1,10]} is a range from but not including 1 to and including 10. This wish, of course, conflicts with the desire to provide delimiter mismatch detection. To accommodate these conflicting goals, syntax/tex.vim provides

```
g:tex_matchcheck = '[({[]'
```

which is shown along with its default setting. So, if one doesn't want [] and () to be checked for mismatches, try using

```
let g:tex_matchcheck= '[{}]'
```

If you don't want matching to occur inside bold and italicized regions,

```
let g:tex_excludematcher= 1
```

will prevent the texMatcher group from being included in those regions.

TF ft-tf-syntax

There is one option for the tf syntax highlighting.

For syncing, minlines defaults to 100. If you prefer another value, you can set "tf_minlines" to the value you desire. Example:

```
:let tf_minlines = your choice
```

TYPESCRIPT ft-typescript-syntax ft-typescriptreact-syntax

There is one option to control the TypeScript syntax highlighting.

g:typescript_host_keyword

When this variable is set to 1, host-specific APIs such as addEventListener are highlighted. To disable set it to zero in your .vimrc:

```
let g:typescript_host_keyword = 0
```

The default value is 1.

TYPST ft-typst-syntax

g:typst_embedded_languages

Typst files can embed syntax highlighting for other languages by setting the g:typst_embedded_languages variable. This variable is a list of language names whose syntax definitions will be included in Typst files. Example:

```
let g:typst_embedded_languages = ['python', 'r']
```

VIM ft-vim-syntax g:vimsyn_minlines g:vimsyn_maxlines

There is a trade-off between more accurate syntax highlighting versus screen updating speed. To improve accuracy, you may wish to increase the g:vimsyn_minlines variable. The g:vimsyn_maxlines variable may be used to improve screen updating rates (see :syn-sync for more on this).

```
g:vimsyn_minlines : used to set synchronization minlines
g:vimsyn_maxlines : used to set synchronization maxlines
```

(g:vim_minlines and g:vim_maxlines are deprecated variants of
these two options)

g:vimsyn_embed

The g:vimsyn_embed option allows users to select what, if any, types of
embedded script highlighting they wish to have.

```
g:vimsyn_embed == 0       : disable (don't embed any scripts)
g:vimsyn_embed ==# 'lpPr' : support embedded Lua, Perl, Python and Ruby
```

By default, g:vimsyn_embed is unset, and embedded Lua scripts are supported.

g:vimsyn_folding

Some folding is now supported with when 'foldmethod' is set to "syntax":

```
g:vimsyn_folding == 0 or doesn't exist: no syntax-based folding
g:vimsyn_folding =~# 'a' : fold augroups
g:vimsyn_folding =~# 'f' : fold functions
g:vimsyn_folding =~# 'h' : fold let heredocs
g:vimsyn_folding =~# 'l' : fold Lua      heredocs
g:vimsyn_folding =~# 'p' : fold Perl     heredocs
g:vimsyn_folding =~# 'P' : fold Python   heredocs
g:vimsyn_folding =~# 'r' : fold Ruby     heredocs
```

By default, g:vimsyn_folding is unset. Concatenate the indicated characters
to support folding of multiple syntax constructs (e.g.,
g:vimsyn_folding = "fh" will enable folding of both functions and heredocs).

g:vimsyn_comment_strings

By default, strings are highlighted inside comments. This may be disabled by
setting g:vimsyn_comment_strings to false.

g:vimsyn_noerror

Not all error highlighting that syntax/vim.vim does may be correct; Vim script
is a difficult language to highlight correctly. A way to suppress error
highlighting is to put the following line in your vimrc:

```
let g:vimsyn_noerror = 1
```

WDL **wdl-syntax**

The Workflow Description Language is a way to specify data processing
workflows with a human-readable and writeable syntax. This is used a lot in
bioinformatics. More info on the spec can be found here:
https://github.com/openwdl/wdl

XF86CONFIG **ft-xf86conf-syntax**

The syntax of XF86Config file differs in XFree86 v3.x and v4.x. Both
variants are supported. Automatic detection is used, but is far from perfect.
You may need to specify the version manually. Set the variable
xf86conf_xfree86_version to 3 or 4 according to your XFree86 version in
your vimrc. Example:

```
:let xf86conf_xfree86_version=3
```

When using a mix of versions, set the b:xf86conf_xfree86_version variable.

Note that spaces and underscores in option names are not supported. Use
"SyncOnGreen" instead of "__s yn con gr_e_e_n" if you want the option name
highlighted.

XML **ft-xml-syntax**

Xml namespaces are highlighted by default. This can be inhibited by
setting a global variable:

```
:let g:xml_namespace_transparent=1
```

xml-folding

The xml syntax file provides syntax folding (see :syn-fold) between
start and end tags. This can be turned on by

```
:let g:xml_syntax_folding = 1
:set foldmethod=syntax
```

Note: Syntax folding might slow down syntax highlighting significantly,
especially for large files.

X Pixmaps (XPM) ft-xpm-syntax

xpm.vim creates its syntax items dynamically based upon the contents of the
XPM file. Thus if you make changes e.g. in the color specification strings,
you have to source it again e.g. with ":set syn=xpm".

To copy a pixel with one of the colors, yank a "pixel" with "yl" and insert it
somewhere else with "P".

Do you want to draw with the mouse? Try the following:

```
:function! GetPixel()
:   let c = getline(".")[col(".") - 1]
:   echo c
:   exe "noremap <LeftMouse> <LeftMouse>r" .. c
:   exe "noremap <LeftDrag>     <LeftMouse>r" .. c
:endfunction
:noremap <RightMouse> <LeftMouse>:call GetPixel()<CR>
:set guicursor=n:hor20     " to see the color beneath the cursor
```

This turns the right button into a pipette and the left button into a pen.
It will work with XPM files that have one character per pixel only and you
must not click outside of the pixel strings, but feel free to improve it.

It will look much better with a font in a quadratic cell size, e.g. for X:

```
:set guifont=-*-clean-medium-r-*-*-8-*-*-*-*-80-*
```

YAML ft-yaml-syntax

g:yaml_schema b:yaml_schema

A YAML schema is a combination of a set of tags and a mechanism for resolving
non-specific tags. For user this means that YAML parser may, depending on
plain scalar contents, treat plain scalar (which can actually be only string
and nothing else) as a value of the other type: null, boolean, floating-point,
integer. g:yaml_schema option determines according to which schema values
will be highlighted specially. Supported schemas are

Schema	Description
failsafe	No additional highlighting.
json	Supports JSON-style numbers, booleans and null.
core	Supports more number, boolean and null styles.
pyyaml	In addition to core schema supports highlighting timestamps, but there are some differences in what is recognized as numbers and many additional boolean values not present in core schema.

Default schema is core.

Note that schemas are not actually limited to plain scalars, but this is the
only difference between schemas defined in YAML specification and the only
difference defined in the syntax file.

ZSH ft-zsh-syntax

The syntax script for zsh allows for syntax-based folding:

```
:let g:zsh_fold_enable = 1
```

6. Defining a syntax :syn-define E410

Vim understands three types of syntax items:

1. Keyword

   It can only contain keyword characters, according to the characters
   specified with :syn-iskeyword or the 'iskeyword' option. It cannot
   contain other syntax items. It will only match with a complete word (there
   are no keyword characters before or after the match). The keyword "if"
   would match in "if(a=b)", but not in "ifdef x", because "(" is not a
   keyword character and "d" is.
2. Match

   This is a match with a single regexp pattern.
3. Region

   This starts at a match of the "start" regexp pattern and ends with a match
   with the "end" regexp pattern. Any other text can appear in between. A
   "skip" regexp pattern can be used to avoid matching the "end" pattern.

Several syntax ITEMs can be put into one syntax GROUP. For a syntax group
you can give highlighting attributes. For example, you could have an item
to define a /* ... */ comment and another one that defines a "// ..."
comment, and put them both in the "Comment" group. You can then specify that
a "Comment" will be in bold font and have a blue color. You are free to make
one highlight group for one syntax item, or put all items into one group.
This depends on how you want to specify your highlighting attributes. Putting
each item in its own group results in having to specify the highlighting
for a lot of groups.

Note that a syntax group and a highlight group are similar. For a highlight
group you will have given highlight attributes. These attributes will be used
for the syntax group with the same name.

In case more than one item matches at the same position, the one that was defined LAST wins. Thus you can override previously defined syntax items by using an item that matches the same text. But a keyword always goes before a match or region. And a keyword with matching case always goes before a keyword with ignoring case.

PRIORITY :syn-priority

When several syntax items may match, these rules are used:

1. When multiple Match or Region items start in the same position, the item defined last has priority.
2. A Keyword has priority over Match and Region items.
3. An item that starts in an earlier position has priority over items that start in later positions.

DEFINING CASE :syn-case E390

:sy[ntax] case [match | ignore]
This defines if the following ":syntax" commands will work with matching case, when using "match", or with ignoring case, when using "ignore". Note that any items before this are not affected, and all items until the next ":syntax case" command are affected.

:sy[ntax] case
Show either "syntax case match" or "syntax case ignore".

DEFINING FOLDLEVEL :syn-foldlevel

:sy[ntax] foldlevel start
:sy[ntax] foldlevel minimum
This defines how the foldlevel of a line is computed when using foldmethod=syntax (see fold-syntax and :syn-fold):

start: Use level of item containing start of line.
minimum: Use lowest local-minimum level of items on line.

The default is "start". Use "minimum" to search a line horizontally for the lowest level contained on the line that is followed by a higher level. This produces more natural folds when syntax items may close and open horizontally within a line.

:sy[ntax] foldlevel
Show the current foldlevel method, either "syntax foldlevel start" or "syntax foldlevel minimum".

SPELL CHECKING :syn-spell

:sy[ntax] spell toplevel
:sy[ntax] spell notoplevel
:sy[ntax] spell default
This defines where spell checking is to be done for text that is not in a syntax item:

toplevel: Text is spell checked.
notoplevel: Text is not spell checked.
default: When there is a @Spell cluster no spell checking.

For text in syntax items use the @Spell and @NoSpell clusters spell-syntax. When there is no @Spell and no @NoSpell cluster then spell checking is done for "default" and "toplevel".

To activate spell checking the 'spell' option must be set.

:sy[ntax] spell
Show the current syntax spell checking method, either "syntax spell toplevel", "syntax spell notoplevel" or "syntax spell default".

SYNTAX ISKEYWORD SETTING :syn-iskeyword

:sy[ntax] iskeyword [clear | {option}]
This defines the keyword characters. It's like the 'iskeyword' option for but only applies to syntax highlighting.

clear: Syntax specific iskeyword setting is disabled and the buffer-local 'iskeyword' setting is used.
{option} Set the syntax 'iskeyword' option to a new value.

Example:

```
:syntax iskeyword @,48-57,192-255,$,_
```

This would set the syntax specific iskeyword option to include all alphabetic characters, plus the numeric characters, all accented characters and also includes the "_" and the "$".

If no argument is given, the current value will be output.

Setting this option influences what /\k matches in syntax patterns and also determines where :syn-keyword will be checked for a new match.

It is recommended when writing syntax files, to use this command to
set the correct value for the specific syntax language and not change
the 'iskeyword' option.

DEFINING KEYWORDS :syn-keyword

:sy[ntax] keyword {group-name} [{options}] {keyword} ... [{options}]

This defines a number of keywords.

{group-name}   Is a syntax group name such as "Comment".
[{options}]   See :syn-arguments below.
{keyword} ...   Is a list of keywords which are part of this group.

Example:

```
:syntax keyword   Type   int long char
```

The {options} can be given anywhere in the line. They will apply to
all keywords given, also for options that come after a keyword.
These examples do exactly the same:

```
:syntax keyword   Type   contained int long char
:syntax keyword   Type   int long contained char
:syntax keyword   Type   int long char contained
```

E789 E890

When you have a keyword with an optional tail, like Ex commands in
Vim, you can put the optional characters inside [], to define all the
variations at once:

```
:syntax keyword   vimCommand     ab[breviate] n[ext]
```

Don't forget that a keyword can only be recognized if all the
characters are included in the 'iskeyword' option. If one character
isn't, the keyword will never be recognized.
Multi-byte characters can also be used. These do not have to be in
'iskeyword'.
See :syn-iskeyword for defining syntax specific iskeyword settings.

A keyword always has higher priority than a match or region, the
keyword is used if more than one item matches. Keywords do not nest
and a keyword can't contain anything else.

Note that when you have a keyword that is the same as an option (even
one that isn't allowed here), you can not use it. Use a match
instead.

The maximum length of a keyword is 80 characters.

The same keyword can be defined multiple times, when its containment
differs. For example, you can define the keyword once not contained
and use one highlight group, and once contained, and use a different
highlight group. Example:

```
:syn keyword vimCommand tag
:syn keyword vimSetting contained tag
```

When finding "tag" outside of any syntax item, the "vimCommand"
highlight group is used. When finding "tag" in a syntax item that
contains "vimSetting", the "vimSetting" group is used.

DEFINING MATCHES :syn-match

:sy[ntax] match {group-name} [{options}]
                [excludenl]
                [keepend]
                {pattern}
                [{options}]

This defines one match.

{group-name}   A syntax group name such as "Comment".
[{options}]   See :syn-arguments below.
[excludenl]   Don't make a pattern with the end-of-line "$"
                        extend a containing match or region. Must be
                        given before the pattern. :syn-excludenl
keepend   Don't allow contained matches to go past a
                        match with the end pattern. See
                        :syn-keepend.
{pattern}   The search pattern that defines the match.
                        See :syn-pattern below.
                        Note that the pattern may match more than one
                        line, which makes the match depend on where
                        Vim starts searching for the pattern. You
                        need to make sure syncing takes care of this.

Example (match a character constant):

```
:syntax match Character /'.'/hs=s+1,he=e-1
```

DEFINING REGIONS :syn-region :syn-start :syn-skip :syn-end

E398 E399

:sy[ntax] region {group-name} [{options}]
                [matchgroup={group-name}]

```
        [keepend]
        [extend]
        [excludenl]
        start={start-pattern} ...
        [skip={skip-pattern}]
        end={end-pattern} ...
        [{options}]
```

This defines one region. It may span several lines.

{group-name}	A syntax group name such as "Comment".
[{options}]	See :syn-arguments below.
[matchgroup={group-name}]	The syntax group to use for the following start or end pattern matches only. Not used for the text in between the matched start and end patterns. Use NONE to reset to not using a different group for the start or end match. See :syn-matchgroup.
keepend	Don't allow contained matches to go past a match with the end pattern. See :syn-keepend.
extend	Override a "keepend" for an item this region is contained in. See :syn-extend.
excludenl	Don't make a pattern with the end-of-line "$" extend a containing match or item. Only useful for end patterns. Must be given before the patterns it applies to. :syn-excludenl
start={start-pattern}	The search pattern that defines the start of the region. See :syn-pattern below.
skip={skip-pattern}	The search pattern that defines text inside the region where not to look for the end pattern. See :syn-pattern below.
end={end-pattern}	The search pattern that defines the end of the region. See :syn-pattern below.

Example:

```
:syntax region String   start=+"+  skip=+\\"+  end=+"+
```

The start/skip/end patterns and the options can be given in any order. There can be zero or one skip pattern. There must be one or more start and end patterns. This means that you can omit the skip pattern, but you must give at least one start and one end pattern. It is allowed to have white space before and after the equal sign (although it mostly looks better without white space).

When more than one start pattern is given, a match with one of these is sufficient. This means there is an OR relation between the start patterns. The last one that matches is used. The same is true for the end patterns.

The search for the end pattern starts right after the start pattern. Offsets are not used for this. This implies that the match for the end pattern will never overlap with the start pattern.

The skip and end pattern can match across line breaks, but since the search for the pattern can start in any line it often does not do what you want. The skip pattern doesn't avoid a match of an end pattern in the next line. Use single-line patterns to avoid trouble.

Note: The decision to start a region is only based on a matching start pattern. There is no check for a matching end pattern. This does NOT work:

```
:syn region First  start="("  end=":"
:syn region Second start="("  end=";"
```

The Second always matches before the First (last defined pattern has higher priority). The Second region then continues until the next ';', no matter if there is a ':' before it. Using a match does work:

```
:syn match First  "(\_.\{-}:"
:syn match Second "(\_.\{-};"
```

This pattern matches any character or line break with "_." and repeats that with "\{-}" (repeat as few as possible).

:syn-keepend

By default, a contained match can obscure a match for the end pattern. This is useful for nesting. For example, a region that starts with "{" and ends with "}", can contain another region. An encountered "}" will then end the contained region, but not the outer region:

```
    {           starts outer "{}" region
        {       starts contained "{}" region
        }       ends contained "{}" region
    }           ends outer "{} region
```

If you don't want this, the "keepend" argument will make the matching of an end pattern of the outer region also end any contained item. This makes it impossible to nest the same region, but allows for contained items to highlight parts of the end pattern, without causing that to skip the match with the end pattern. Example:

```
:syn match  vimComment +"[^"]\+$+
:syn region vimCommand start="set" end="$" contains=vimComment keepend
```

The "keepend" makes the vimCommand always end at the end of the line,
even though the contained vimComment includes a match with the <EOL>.

When "keepend" is not used, a match with an end pattern is retried
after each contained match. When "keepend" is included, the first
encountered match with an end pattern is used, truncating any
contained matches.

:syn-extend

The "keepend" behavior can be changed by using the "extend" argument.
When an item with "extend" is contained in an item that uses
"keepend", the "keepend" is ignored and the containing region will be
extended.
This can be used to have some contained items extend a region while
others don't. Example:

```
:syn region htmlRef start=+<a>+ end=+</a>+ keepend contains=htmlItem,htmlScript
:syn match htmlItem +<[^>]*>+ contained
:syn region htmlScript start=+<script+ end=+</script[^>]*>+ contained extend
```

Here the htmlItem item does not make the htmlRef item continue
further, it is only used to highlight the <> items. The htmlScript
item does extend the htmlRef item.

Another example:

```
:syn region xmlFold start="<a>" end="</a>" fold transparent keepend extend
```

This defines a region with "keepend", so that its end cannot be
changed by contained items, like when the "" is matched to
highlight it differently. But when the xmlFold region is nested (it
includes itself), the "extend" applies, so that the "" of a nested
region only ends that region, and not the one it is contained in.

:syn-excludenl

When a pattern for a match or end pattern of a region includes a '$'
to match the end-of-line, it will make a region item that it is
contained in continue on the next line. For example, a match with
"\\$" (backslash at the end of the line) can make a region continue
that would normally stop at the end of the line. This is the default
behavior. If this is not wanted, there are two ways to avoid it:

1. Use "keepend" for the containing item. This will keep all
   contained matches from extending the match or region. It can be
   used when all contained items must not extend the containing item.
2. Use "excludenl" in the contained item. This will keep that match
   from extending the containing match or region. It can be used if
   only some contained items must not extend the containing item.
   "excludenl" must be given before the pattern it applies to.

:syn-matchgroup

"matchgroup" can be used to highlight the start and/or end pattern
differently than the body of the region. Example:

```
:syntax region String matchgroup=Quote start=+"+  skip=+\\"+    end=+"+
```

This will highlight the quotes with the "Quote" group, and the text in
between with the "String" group.
The "matchgroup" is used for all start and end patterns that follow,
until the next "matchgroup". Use "matchgroup=NONE" to go back to not
using a matchgroup.

In a start or end pattern that is highlighted with "matchgroup" the
contained items of the region are not used. This can be used to avoid
that a contained item matches in the start or end pattern match. When
using "transparent", this does not apply to a start or end pattern
match that is highlighted with "matchgroup".

Here is an example, which highlights three levels of parentheses in
different colors:

```
:sy region par1 matchgroup=par1 start=/(/ end=/)/ contains=par2
:sy region par2 matchgroup=par2 start=/(/ end=/)/ contains=par3 contained
:sy region par3 matchgroup=par3 start=/(/ end=/)/ contains=par1 contained
:hi par1 ctermfg=red guifg=red
:hi par2 ctermfg=blue guifg=blue
:hi par3 ctermfg=darkgreen guifg=darkgreen
```

E849

The maximum number of syntax groups is 19999.

7. :syntax arguments :syn-arguments

The :syntax commands that define syntax items take a number of arguments.
The common ones are explained here. The arguments may be given in any order
and may be mixed with patterns.

Not all commands accept all arguments. This table shows which arguments
can not be used for all commands:

E395

	contains	oneline	fold	display	extend	concealends~
:syntax keyword	-	-	-	-	-	-
:syntax match	yes	-	yes	yes	yes	-
:syntax region	yes	yes	yes	yes	yes	yes

These arguments can be used for all three commands:

- conceal
- cchar
- contained
- containedin
- nextgroup
- transparent
- skipwhite
- skipnl
- skipempty

conceal conceal :syn-conceal

When the "conceal" argument is given, the item is marked as concealable.
Whether or not it is actually concealed depends on the value of the
'conceallevel' option. The 'concealcursor' option is used to decide whether
concealable items in the current line are displayed unconcealed to be able to
edit the line.

Another way to conceal text is with matchadd(), but internally this works a
bit differently syntax-vs-match.

concealends :syn-concealends

When the "concealends" argument is given, the start and end matches of
the region, but not the contents of the region, are marked as concealable.
Whether or not they are actually concealed depends on the setting on the
'conceallevel' option. The ends of a region can only be concealed separately
in this way when they have their own highlighting via "matchgroup". The
synconcealed() function can be used to retrieve information about concealed
items.

cchar :syn-cchar

E844

The "cchar" argument defines the character shown in place of the item
when it is concealed (setting "cchar" only makes sense when the conceal
argument is given.) If "cchar" is not set then the default conceal
character defined in the 'listchars' option is used. The character cannot be
a control character such as Tab. Example:

```
:syntax match Entity "&amp;" conceal cchar=&
```

See hl-Conceal for highlighting.

contained :syn-contained

When the "contained" argument is given, this item will not be recognized at
the top level, but only when it is mentioned in the "contains" field of
another match. Example:

```
:syntax keyword Todo    TODO    contained
:syntax match   Comment "//.*"  contains=Todo
```

display :syn-display

If the "display" argument is given, this item will be skipped when the
detected highlighting will not be displayed. This will speed up highlighting,
by skipping this item when only finding the syntax state for the text that is
to be displayed.

Generally, you can use "display" for match and region items that meet these
conditions:

- The item does not continue past the end of a line. Example for C: A region
  for a "/*" comment can't contain "display", because it continues on the next
  line.
- The item does not contain items that continue past the end of the line or
  make it continue on the next line.
- The item does not change the size of any item it is contained in. Example
  for C: A match with "\\$" in a preprocessor match can't have "display",
  because it may make that preprocessor match shorter.

- The item does not allow other items to match that didn't match otherwise,

  and that item may extend the match too far. Example for C: A match for a
  "//" comment can't use "display", because a "/*" inside that comment would
  match then and start a comment which extends past the end of the line.

Examples, for the C language, where "display" can be used:
- match with a number

- match with a label

transparent :syn-transparent

If the "transparent" argument is given, this item will not be highlighted
itself, but will take the highlighting of the item it is contained in. This
is useful for syntax items that don't need any highlighting but are used
only to skip over a part of the text.

The "contains=" argument is also inherited from the item it is contained in,
unless a "contains" argument is given for the transparent item itself. To
avoid that unwanted items are contained, use "contains=NONE". Example, which
highlights words in strings, but makes an exception for "vim":

```
:syn match myString /'[^']*'/ contains=myWord,myVim
:syn match myWord   /\<[a-z]*\>/ contained
:syn match myVim    /\<vim\>/ transparent contained contains=NONE
:hi link myString String
:hi link myWord   Comment
```

Since the "myVim" match comes after "myWord" it is the preferred match (last
match in the same position overrules an earlier one). The "transparent"
argument makes the "myVim" match use the same highlighting as "myString". But
it does not contain anything. If the "contains=NONE" argument would be left
out, then "myVim" would use the contains argument from myString and allow
"myWord" to be contained, which will be highlighted as a Comment. This
happens because a contained match doesn't match inside itself in the same
position, thus the "myVim" match doesn't overrule the "myWord" match here.

When you look at the colored text, it is like looking at layers of contained
items. The contained item is on top of the item it is contained in, thus you
see the contained item. When a contained item is transparent, you can look
through, thus you see the item it is contained in. In a picture:

```
               look from here

           |   |   |   |   |   |
           V   V   V   V   V   V

              xxxx       yyy          more contained items
           ...................        contained item (transparent)
       ============================   first item
```

The 'x', 'y' and '=' represent a highlighted syntax item. The '.' represent a
transparent group.

What you see is:

```
       =======xxxx=======yyy========
```

Thus you look through the transparent "....".

oneline :syn-oneline

The "oneline" argument indicates that the region does not cross a line
boundary. It must match completely in the current line. However, when the
region has a contained item that does cross a line boundary, it continues on
the next line anyway. A contained item can be used to recognize a line
continuation pattern. But the "end" pattern must still match in the first
line, otherwise the region doesn't even start.

When the start pattern includes a "\n" to match an end-of-line, the end
pattern must be found in the same line as where the start pattern ends. The
end pattern may also include an end-of-line. Thus the "oneline" argument
means that the end of the start pattern and the start of the end pattern must
be within one line. This can't be changed by a skip pattern that matches a
line break.

fold :syn-fold

The "fold" argument makes the fold level increase by one for this item.
Example:

```
:syn region myFold start="{" end="}" transparent fold
:syn sync fromstart
:set foldmethod=syntax
```

This will make each {} block form one fold.

The fold will start on the line where the item starts, and end where the item
ends. If the start and end are within the same line, there is no fold.
The 'foldnestmax' option limits the nesting of syntax folds.
See :syn-foldlevel to control how the foldlevel of a line is computed
from its syntax items.

:syn-contains E405 E406 E407 E408 E409

contains={group-name},...

The "contains" argument is followed by a list of syntax group names. These groups will be allowed to begin inside the item (they may extend past the containing group's end). This allows for recursive nesting of matches and regions. If there is no "contains" argument, no groups will be contained in this item. The group names do not need to be defined before they can be used here.

contains=ALL
If the only item in the contains list is "ALL", then all groups will be accepted inside the item.

contains=ALLBUT,{group-name},...
If the first item in the contains list is "ALLBUT", then all groups will be accepted inside the item, except the ones that are listed. Example:

```
:syntax region Block start="{" end="}" ... contains=ALLBUT,Function
```

contains=TOP
If the first item in the contains list is "TOP", then all groups will be accepted that don't have the "contained" argument.
contains=TOP,{group-name},...
Like "TOP", but excluding the groups that are listed.

contains=CONTAINED
If the first item in the contains list is "CONTAINED", then all groups will be accepted that have the "contained" argument.
contains=CONTAINED,{group-name},...
Like "CONTAINED", but excluding the groups that are listed.

The {group-name} in the "contains" list can be a pattern. All group names that match the pattern will be included (or excluded, if "ALLBUT" is used). The pattern cannot contain white space or a ','. Example:

```
... contains=Comment.*,Keyw[0-3]
```

The matching will be done at moment the syntax command is executed. Groups that are defined later will not be matched. Also, if the current syntax command defines a new group, it is not matched. Be careful: When putting syntax commands in a file you can't rely on groups NOT being defined, because the file may have been sourced before, and ":syn clear" doesn't remove the group names.

The contained groups will also match in the start and end patterns of a region. If this is not wanted, the "matchgroup" argument can be used :syn-matchgroup. The "ms=" and "me=" offsets can be used to change the region where contained items do match. Note that this may also limit the area that is highlighted

containedin={group-name},... :syn-containedin

The "containedin" argument is followed by a list of syntax group names. The item will be allowed to begin inside these groups. This works as if the containing item has a "contains=" argument that includes this item.

Only the immediate containing item (the one at the top of the syntax stack) is considered. Vim does not search other ancestors. If the immediate container neither contains this item via :syn-contains nor is named in this item's "containedin=", the match will not start even if some ancestor would allow it. Note that a :syn-transparent region still enforces its own :syn-contains list.

The {group-name},... can be used just like for "contains", as explained above.

This is useful when adding a syntax item afterwards. An item can be told to be included inside an already existing item, without changing the definition of that item. For example, to highlight a word in a C comment after loading the C syntax:

```
:syn keyword myword HELP containedin=cComment contained
```

Note that "contained" is also used, to avoid that the item matches at the top level.

Matches for "containedin" are added to the other places where the item can appear. A "contains" argument may also be added as usual. Don't forget that keywords never contain another item, thus adding them to "containedin" won't work.
See also: :syn-contains, :syn-transparent.

nextgroup={group-name},... :syn-nextgroup

The "nextgroup" argument is followed by a list of syntax group names, separated by commas (just like with "contains", so you can also use patterns).

If the "nextgroup" argument is given, the mentioned syntax groups will be tried for a match, after the match or region ends. If none of the groups have a match, highlighting continues normally. If there is a match, this group will be used, even when it is not mentioned in the "contains" field of the

current group. This is like giving the mentioned group priority over all
other groups. Example:

```
:syntax match  ccFoobar  "Foo.\{-}Bar"  contains=ccFoo
:syntax match  ccFoo     "Foo"      contained nextgroup=ccFiller
:syntax region ccFiller  start="."  matchgroup=ccBar  end="Bar"  contained
```

This will highlight "Foo" and "Bar" differently, and only when there is a
"Bar" after "Foo". In the text line below, "f" shows where ccFoo is used for
highlighting, and "bbb" where ccBar is used.

```
Foo asdfasd Bar asdf Foo asdf Bar asdf
fff            bbb      fff      bbb
```

Note the use of ".\{-}" to skip as little as possible until the next Bar.
when .* would be used, the "asdf" in between "Bar" and "Foo" would be
highlighted according to the "ccFoobar" group, because the ccFooBar match
would include the first "Foo" and the last "Bar" in the line (see pattern).

skipwhite :syn-skipwhite

skipnl :syn-skipnl

skipempty :syn-skipempty

These arguments are only used in combination with "nextgroup". They can be
used to allow the next group to match after skipping some text:
        skipwhite   skip over space and tab characters
        skipnl   skip over the end of a line
        skipempty   skip over empty lines (implies a "skipnl")

When "skipwhite" is present, the white space is only skipped if there is no
next group that matches the white space.

When "skipnl" is present, the match with nextgroup may be found in the next
line. This only happens when the current item ends at the end of the current
line! When "skipnl" is not present, the nextgroup will only be found after
the current item in the same line.

When skipping text while looking for a next group, the matches for other
groups are ignored. Only when no next group matches, other items are tried
for a match again. This means that matching a next group and skipping white
space and <EOL>s has a higher priority than other items.

Example:

```
:syn match ifstart "\<if.*"       nextgroup=ifline skipwhite skipempty
:syn match ifline  "[^ \t].*" nextgroup=ifline skipwhite skipempty contained
:syn match ifline  "endif"      contained
```

Note that the [^ \t].* match matches all non-white text. Thus it would also
match "endif". Therefore the "endif" match is put last, so that it takes
precedence.
Note that this example doesn't work for nested "if"s. You need to add
"contains" arguments to make that work (omitted for simplicity of the
example).

IMPLICIT CONCEAL :syn-conceal-implicit

:sy[ntax] conceal [on|off]
        This defines if the following ":syntax" commands will define keywords,
        matches or regions with the "conceal" flag set. After ":syn conceal
        on", all subsequent ":syn keyword", ":syn match" or ":syn region"
        defined will have the "conceal" flag set implicitly. ":syn conceal
        off" returns to the normal state where the "conceal" flag must be
        given explicitly.

:sy[ntax] conceal
        Show either "syntax conceal on" or "syntax conceal off".

8. Syntax patterns :syn-pattern E401 E402

In the syntax commands, a pattern must be surrounded by two identical
characters. This is like it works for the ":s" command. The most common to
use is the double quote. But if the pattern contains a double quote, you can
use another character that is not used in the pattern. Examples:

```
:syntax region Comment  start="/\*"  end="\*/"
:syntax region String   start=+"+    end=+"+     skip=+\\"+
```

See pattern for the explanation of what a pattern is. Syntax patterns are
always interpreted like the 'magic' option is set, no matter what the actual
value of 'magic' is. And the patterns are interpreted like the 'l' flag is
not included in 'cpoptions'. This was done to make syntax files portable and
independent of the 'magic' setting.

Try to avoid patterns that can match an empty string, such as "[a-z]*".
This slows down the highlighting a lot, because it matches everywhere.

:syn-pattern-offset

The pattern can be followed by a character offset. This can be used to
change the highlighted part, and to change the text area included in the
match or region (which only matters when trying to match other items). Both
are relative to the matched pattern. The character offset for a skip
pattern can be used to tell where to continue looking for an end pattern.

The offset takes the form of "{what}={offset}"
The {what} can be one of seven strings:

```
ms      Match Start     offset for the start of the matched text
me      Match End       offset for the end of the matched text
hs      Highlight Start offset for where the highlighting starts
he      Highlight End   offset for where the highlighting ends
rs      Region Start    offset for where the body of a region starts
re      Region End      offset for where the body of a region ends
lc      Leading Context offset past "leading context" of pattern
```

The {offset} can be:

```
s       start of the matched pattern
s+{nr}  start of the matched pattern plus {nr} chars to the right
s-{nr}  start of the matched pattern plus {nr} chars to the left
e       end of the matched pattern
e+{nr}  end of the matched pattern plus {nr} chars to the right
e-{nr}  end of the matched pattern plus {nr} chars to the left
{nr}    (for "lc" only): start matching {nr} chars right of the start
```

Examples: "ms=s+1", "hs=e-2", "lc=3".

Although all offsets are accepted after any pattern, they are not always
meaningful. This table shows which offsets are actually used:

ms	me hs he	rs re	lc
match item	yes yes yes yes	- -	yes
region item start yes - yes -	yes -	yes	
region item skip -	yes - -	- -	yes
region item end -	yes - yes	- yes yes	

Offsets can be concatenated, with a ',' in between. Example:

```
:syn match String  /"[^"]*"/hs=s+1,he=e-1
```

```
    some "string" text
         ^^^^^^               highlighted
```

Notes:

- There must be no white space between the pattern and the character

  offset(s).
- The highlighted area will never be outside of the matched text.

- A negative offset for an end pattern may not always work, because the end

  pattern may be detected when the highlighting should already have stopped.
- Before Vim 7.2 the offsets were counted in bytes instead of characters.

  This didn't work well for multibyte characters, so it was changed with the
  Vim 7.2 release.
- The start of a match cannot be in a line other than where the pattern

  matched. This doesn't work: "a\nb"ms=e. You can make the highlighting
  start in another line, this does work: "a\nb"hs=e.

Example (match a comment but don't highlight the /* and */):

```
:syntax region Comment start="/\*"hs=e+1 end="\*/"he=s-1
```

```
/* this is a comment */
  ^^^^^^^^^^^^^^^^^^     highlighted
```

A more complicated Example:

```
:syn region Exa matchgroup=Foo start="foo"hs=s+2,rs=e+2 matchgroup=Bar end="bar"me=e-1,he=e-1,re=s-1
```

```
abcfoostringbarabc
   mmmmmmmmmmm      match
     sssrrreee      highlight start/region/end ("Foo", "Exa" and "Bar")
```

Leading context :syn-lc :syn-leading :syn-context

Note: This is an obsolete feature, only included for backwards compatibility
with previous Vim versions. It's now recommended to use the /\@<= construct
in the pattern. You can also often use /\zs.

The "lc" offset specifies leading context -- a part of the pattern that must
be present, but is not considered part of the match. An offset of "lc=n" will
cause Vim to step back n columns before attempting the pattern match, allowing
characters which have already been matched in previous patterns to also be

used as leading context for this match. This can be used, for instance, to specify that an "escaping" character must not precede the match:

```
:syn match ZNoBackslash "[^\\]z"ms=s+1
:syn match WNoBackslash "[^\\]w"lc=1
:syn match Underline "_\+"
```

```
         ___zzzz ___wwww
         ^^^     ^^^     matches Underline
             ^ ^         matches ZNoBackslash
                   ^^^^ matches WNoBackslash
```

The "ms" offset is automatically set to the same value as the "lc" offset, unless you set "ms" explicitly.

Multi-line patterns :syn-multi-line

The patterns can include "\n" to match an end-of-line. Mostly this works as expected, but there are a few exceptions.

When using a start pattern with an offset, the start of the match is not allowed to start in a following line. The highlighting can start in a following line though. Using the "\zs" item also requires that the start of the match doesn't move to another line.

The skip pattern can include the "\n", but the search for an end pattern will continue in the first character of the next line, also when that character is matched by the skip pattern. This is because redrawing may start in any line halfway in a region and there is no check if the skip pattern started in a previous line. For example, if the skip pattern is "a\nb" and an end pattern is "b", the end pattern does match in the second line of this:

```
x x a
b x x
```

Generally this means that the skip pattern should not match any characters after the "\n".

External matches :syn-ext-match

These extra regular expression items are available in region patterns:

                                    /\z(/\z(\) E50 E52 E879
    \z(\)   Marks the sub-expression as "external", meaning that it can be
                accessed from another pattern match. Currently only usable in
                defining a syntax region start pattern.

                                    /\z1 /\z2 /\z3 /\z4 /\z5
    \z1 ... \z9   /\z6 /\z7 /\z8 /\z9 E66 E67
                Matches the same string that was matched by the corresponding
                sub-expression in a previous start pattern match.

Sometimes the start and end patterns of a region need to share a common sub-expression. A common example is the "here" document in Perl and many Unix shells. This effect can be achieved with the "\z" special regular expression items, which marks a sub-expression as "external", in the sense that it can be referenced from outside the pattern in which it is defined. The here-document example, for instance, can be done like this:

```
:syn region hereDoc start="<<\z(\I\i*\)" end="^\z1$"
```

As can be seen here, the \z actually does double duty. In the start pattern, it marks the "\(\I\i*\)" sub-expression as external; in the end pattern, it changes the \z1 back-reference into an external reference referring to the first external sub-expression in the start pattern. External references can also be used in skip patterns:

```
:syn region foo start="start \z(\I\i*\)" skip="not end \z1" end="end \z1"
```

Note that normal and external sub-expressions are completely orthogonal and indexed separately; for instance, if the pattern "\z(..\)\(..\)" is applied to the string "aabb", then \1 will refer to "bb" and \z1 will refer to "aa". Note also that external sub-expressions cannot be accessed as back-references within the same pattern like normal sub-expressions. If you want to use one sub-expression as both a normal and an external sub-expression, you can nest the two, as in "\(\z(...\)\)".

Note that only matches within a single line can be used. Multi-line matches cannot be referred to.

9. Syntax clusters :syn-cluster E400

```
:sy[ntax] cluster {cluster-name} [contains={group-name},...]
                                 [add={group-name},...]
                                 [remove={group-name},...]
```

This command allows you to cluster a list of syntax groups together under a single name.

        contains={group-name},...
                The cluster is set to the specified list of groups.
        add={group-name},...
                The specified groups are added to the cluster.

remove={group-name},...
The specified groups are removed from the cluster.

A cluster so defined may be referred to in a contains=..., containedin=..., nextgroup=..., add=... or remove=... list with a "@" prefix. You can also use this notation to implicitly declare a cluster before specifying its contents.

Example:

```
:syntax match Thing "# [^#]\+ #" contains=@ThingMembers
:syntax cluster ThingMembers contains=ThingMember1,ThingMember2
```

As the previous example suggests, modifications to a cluster are effectively retroactive; the membership of the cluster is checked at the last minute, so to speak:

```
:syntax keyword A aaa
:syntax keyword B bbb
:syntax cluster AandB contains=A
:syntax match Stuff "( aaa bbb )" contains=@AandB
:syntax cluster AandB add=B       " now both keywords are matched in Stuff
```

This also has implications for nested clusters:

```
:syntax keyword A aaa
:syntax keyword B bbb
:syntax cluster SmallGroup contains=B
:syntax cluster BigGroup contains=A,@SmallGroup
:syntax match Stuff "( aaa bbb )" contains=@BigGroup
:syntax cluster BigGroup remove=B       " no effect, since B isn't in BigGroup
:syntax cluster SmallGroup remove=B     " now bbb isn't matched within Stuff
```

E848

The maximum number of clusters is 9767.

10. Including syntax files

:syn-include E397

It is often useful for one language's syntax file to include a syntax file for a related language. Depending on the exact relationship, this can be done in two different ways:

- If top-level syntax items in the included syntax file are to be

  allowed at the top level in the including syntax, you can simply use the :runtime command:

```
" In cpp.vim:
:runtime! syntax/c.vim
:unlet b:current_syntax
```

- If top-level syntax items in the included syntax file are to be

  contained within a region in the including syntax, you can use the ":syntax include" command:

:sy[ntax] include [@{grouplist-name}] {file-name}

All syntax items declared in the included file will have the "contained" flag added. In addition, if a group list is specified, all top-level syntax items in the included file will be added to that list.

```
" In perl.vim:
:syntax include @Pod <script>:p:h/pod.vim
:syntax region perlPOD start="^=head" end="^=cut" contains=@Pod
```

When {file-name} is an absolute path (starts with "/", "c:", "$VAR" or "<script>") that file is sourced. When it is a relative path (e.g., "syntax/pod.vim") the file is searched for in 'runtimepath'. All matching files are loaded. Using a relative path is recommended, because it allows a user to replace the included file with their own version, without replacing the file that does the ":syn include".

E847

The maximum number of includes is 999.

11. Synchronizing

:syn-sync E403 E404

Vim wants to be able to start redrawing in any position in the document. To make this possible it needs to know the syntax state at the position where redrawing starts.

:sy[ntax] sync [ccomment [group-name] | minlines={N} | ...]

There are four ways to synchronize:

1. Always parse from the start of the file.

   :syn-sync-first
2. Based on C-style comments. Vim understands how C-comments work and can

   figure out if the current line starts inside or outside a comment.
   :syn-sync-second
3. Jumping back a certain number of lines and start parsing there.

   :syn-sync-third
4. Searching backwards in the text for a pattern to sync on.

   :syn-sync-fourth

:syn-sync-maxlines :syn-sync-minlines

For the last three methods, the line range where the parsing can start is limited by "minlines" and "maxlines".

If the "minlines={N}" argument is given, the parsing always starts at least that many lines backwards. This can be used if the parsing may take a few lines before it's correct, or when it's not possible to use syncing.

If the "maxlines={N}" argument is given, the number of lines that are searched for a comment or syncing pattern is restricted to N lines backwards (after adding "minlines"). This is useful if you have few things to sync on and a slow machine. Example:

```
:syntax sync maxlines=500 ccomment
```

:syn-sync-linebreaks

When using a pattern that matches multiple lines, a change in one line may cause a pattern to no longer match in a previous line. This means has to start above where the change was made. How many lines can be specified with the "linebreaks" argument. For example, when a pattern may include one line break use this:

```
:syntax sync linebreaks=1
```

The result is that redrawing always starts at least one line before where a change was made. The default value for "linebreaks" is zero. Usually the value for "minlines" is bigger than "linebreaks".

First syncing method: :syn-sync-first

```
:syntax sync fromstart
```

The file will be parsed from the start. This makes syntax highlighting accurate, but can be slow for long files. Vim caches previously parsed text, so that it's only slow when parsing the text for the first time. However, when making changes some part of the text needs to be parsed again (worst case: to the end of the file).

Using "fromstart" is equivalent to using "minlines" with a very large number.

Second syncing method: :syn-sync-second :syn-sync-ccomment

For the second method, only the "ccomment" argument needs to be given. Example:

```
:syntax sync ccomment
```

When Vim finds that the line where displaying starts is inside a C-style comment, the last region syntax item with the group-name "Comment" will be used. This requires that there is a region with the group-name "Comment"! An alternate group name can be specified, for example:

```
:syntax sync ccomment javaComment
```

This means that the last item specified with "syn region javaComment" will be used for the detected C comment region. This only works properly if that region does have a start pattern "\/*" and an end pattern "*\/".

The "maxlines" argument can be used to restrict the search to a number of lines. The "minlines" argument can be used to at least start a number of lines back (e.g., for when there is some construct that only takes a few lines, but it hard to sync on).

Note: Syncing on a C comment doesn't work properly when strings are used that cross a line and contain a "*/". Since letting strings cross a line is a bad programming habit (many compilers give a warning message), and the chance of a "*/" appearing inside a comment is very small, this restriction is hardly ever noticed.

Third syncing method: :syn-sync-third

For the third method, only the "minlines={N}" argument needs to be given.
Vim will subtract {N} from the line number and start parsing there. This
means {N} extra lines need to be parsed, which makes this method a bit slower.
Example:

```
:syntax sync minlines=50
```

"lines" is equivalent to "minlines" (used by older versions).

Fourth syncing method: :syn-sync-fourth

The idea is to synchronize on the end of a few specific regions, called a
sync pattern. Only regions can cross lines, so when we find the end of some
region, we might be able to know in which syntax item we are. The search
starts in the line just above the one where redrawing starts. From there
the search continues backwards in the file.

This works just like the non-syncing syntax items. You can use contained
matches, nextgroup, etc. But there are a few differences:

- Keywords cannot be used.
- The syntax items with the "sync" keyword form a completely separated group of syntax items. You can't mix syncing groups and non-syncing groups.
- The matching works backwards in the buffer (line by line), instead of forwards.
- A line continuation pattern can be given. It is used to decide which group of lines need to be searched like they were one line. This means that the search for a match with the specified items starts in the first of the consecutive lines that contain the continuation pattern.
- When using "nextgroup" or "contains", this only works within one line (or group of continued lines).
- When using a region, it must start and end in the same line (or group of continued lines). Otherwise the end is assumed to be at the end of the line (or group of continued lines).
- When a match with a sync pattern is found, the rest of the line (or group of continued lines) is searched for another match. The last match is used. This is used when a line can contain both the start and the end of a region (e.g., in a C-comment like /* this */, the last "*/" is used).

There are two ways how a match with a sync pattern can be used:

1. Parsing for highlighting starts where redrawing starts (and where the search for the sync pattern started). The syntax group that is expected to be valid there must be specified. This works well when the regions that cross lines cannot contain other regions.
2. Parsing for highlighting continues just after the match. The syntax group that is expected to be present just after the match must be specified. This can be used when the previous method doesn't work well. It's much slower, because more text needs to be parsed.

Both types of sync patterns can be used at the same time.

Besides the sync patterns, other matches and regions can be specified, to
avoid finding unwanted matches.

[The reason that the sync patterns are given separately, is that mostly the
search for the sync point can be much simpler than figuring out the
highlighting. The reduced number of patterns means it will go (much)
faster.]

syn-sync-grouphere E393 E394

:syntax sync match {sync-group-name} grouphere {group-name} "pattern" ...

Define a match that is used for syncing. {group-name} is the
name of a syntax group that follows just after the match. Parsing
of the text for highlighting starts just after the match. A region
must exist for this {group-name}. The first one defined will be used.
"NONE" can be used for when there is no syntax group after the match.

syn-sync-groupthere

:syntax sync match {sync-group-name} groupthere {group-name} "pattern" ...

Like "grouphere", but {group-name} is the name of a syntax group that
is to be used at the start of the line where searching for the sync
point started. The text between the match and the start of the sync
pattern searching is assumed not to change the syntax highlighting.
For example, in C you could search backwards for "/*" and "*/". If
"/*" is found first, you know that you are inside a comment, so the

"groupthere" is "cComment". If "*/" is found first, you know that you are not in a comment, so the "groupthere" is "NONE". (in practice it's a bit more complicated, because the "/*" and "*/" could appear inside a string. That's left as an exercise to the reader...).

:syntax sync match ...
:syntax sync region ...

Without a "groupthere" argument. Define a region or match that is skipped while searching for a sync point.

syn-sync-linecont

:syntax sync linecont {pattern}

When {pattern} matches in a line, it is considered to continue in the next line. This means that the search for a sync point will consider the lines to be concatenated.

If the "maxlines={N}" argument is given too, the number of lines that are searched for a match is restricted to N. This is useful if you have very few things to sync on and a slow machine. Example:

```
:syntax sync maxlines=100
```

You can clear all sync settings with:

```
:syntax sync clear
```

You can clear specific sync patterns with:

```
:syntax sync clear {sync-group-name} ...
```

12. Listing syntax items

:syntax :sy :syn :syn-list

This command lists all the syntax items:

```
:sy[ntax] [list]
```

To show the syntax items for one syntax group:

```
:sy[ntax] list {group-name}
```

To list the syntax groups in one cluster: E392

```
:sy[ntax] list @{cluster-name}
```

See above for other arguments for the ":syntax" command.

Note that the ":syntax" command can be abbreviated to ":sy", although ":syn" is mostly used, because it looks better.

13. Highlight command

:highlight :hi E28 E411 E415

Nvim uses a range of highlight groups which fall into two categories: Editor interface and syntax highlighting. In rough order of importance, these are

- basic editor highlight-groups
- standard syntax group-names (in addition, syntax files can define language-specific groups, which are prefixed with the language name)
- diagnostic-highlights
- treesitter-highlight-groups
- lsp-semantic-highlight groups
- lsp-highlight of symbols and references

Where appropriate, highlight groups are linked by default to one of the more basic groups, but colorschemes are expected to cover all of them. Under each tag, the corresponding highlight groups are highlighted using the current colorscheme.

:colo :colorscheme E185

:colo[rscheme] Output the name of the currently active color scheme. This is basically the same as

```
:echo g:colors_name
```

In case g:colors_name has not been defined :colo will
output "default".

:colo[rscheme] {name} Load color scheme {name}. This searches 'runtimepath'
for the file "colors/{name}.{vim,lua}". The first one
that is found is loaded.
Note: "colors/{name}.vim" is tried first.
Also searches all plugins in 'packpath', first below
"start" and then under "opt".

Doesn't work recursively, thus you can't use
":colorscheme" in a color scheme script.

To customize a color scheme use another name, e.g.
"~/.config/nvim/colors/mine.vim", and use :runtime to
load the original color scheme:

```
runtime colors/evening.vim
hi Statement ctermfg=Blue guifg=Blue
```

Before the color scheme will be loaded the
ColorSchemePre autocommand event is triggered.
After the color scheme has been loaded the
ColorScheme autocommand event is triggered.
For info about writing a color scheme file:

```
:edit $VIMRUNTIME/colors/README.txt
```

:hi[ghlight] List all the current highlight groups that have
attributes set.

:hi[ghlight] {group-name}
List one highlight group.

highlight-clear :hi-clear

:hi[ghlight] clear Reset all highlighting to the defaults. Removes all
highlighting for groups added by the user.
Uses the current value of 'background' to decide which
default colors to use.
If there was a default link, restore it. :hi-link

:hi[ghlight] clear {group-name}
:hi[ghlight] {group-name} NONE
Disable the highlighting for one highlight group. It
is _not_ set back to the default colors.

:hi[ghlight] [default] {group-name} {key}={arg} ...
Add a highlight group, or change the highlighting for
an existing group.
See highlight-args for the {key}={arg} arguments.
See :highlight-default for the optional [default]
argument.

Normally a highlight group is added once when starting up. This sets the
default values for the highlighting. After that, you can use additional
highlight commands to change the arguments that you want to set to non-default
values. The value "NONE" can be used to switch the value off or go back to
the default value.

A simple way to change colors is with the :colorscheme command. This loads
a file with ":highlight" commands such as this:

```
:hi Comment     gui=bold
```

Note that all settings that are not included remain the same, only the
specified field is used, and settings are merged with previous ones. So, the
result is like this single command has been used:

```
:hi Comment     ctermfg=Cyan guifg=#80a0ff gui=bold
```

:highlight-verbose

When listing a highlight group and 'verbose' is non-zero, the listing will
also tell where it was last set. Example:

```
:verbose hi Comment
```

Comment   xxx ctermfg=4 guifg=Blue
Last set from /home/mool/vim/vim7/runtime/syntax/syncolor.vim

When ":hi clear" is used then the script where this command is used will be
mentioned for the default values. See :verbose-cmd for more information.

highlight-args E416 E417 E423

There are two types of UIs for highlighting:
cterm   terminal UI (TUI)
gui   GUI or RGB-capable TUI ('termguicolors')

For each type the highlighting can be given. This makes it possible to use
the same syntax file on all UIs.

1. TUI highlight arguments

bold underline undercurl
underdouble underdotted
underdashed inverse italic
standout strikethrough altfont
dim blink hl-conceal overline nocombine

cterm={attr-list} attr-list highlight-cterm E418

attr-list is a comma-separated list (without spaces) of the following items (in any order):

bold	
underline	
undercurl	curly underline
underdouble	double underline
underdotted	dotted underline
underdashed	dashed underline
strikethrough	
reverse	
inverse	same as reverse
italic	
standout	
altfont	
dim	half-bright/faint text
blink	blinking text
conceal	concealed/hidden text
overline	overlined text
nocombine	override attributes instead of combining them
NONE	no attributes used (used to reset it)

Note that "bold" can be used here and by using a bold font. They have the same effect.
"undercurl", "underdouble", "underdotted", and "underdashed" fall back to "underline" in a terminal that does not support them. The color is set using guisp.

start={term-list} highlight-start E422
stop={term-list} term-list highlight-stop

These lists of terminal codes can be used to get non-standard attributes on a terminal.

The escape sequence specified with the "start" argument is written before the characters in the highlighted area. It can be anything that you want to send to the terminal to highlight this area. The escape sequence specified with the "stop" argument is written after the highlighted area. This should undo the "start" argument. Otherwise the screen will look messed up.

{term-list} is a string with escape sequences. This is any string of characters, except that it can't start with "t_" and blanks are not allowed. The <> notation is recognized here, so you can use things like "<Esc>" and "<Space>". Example:

```
start=<Esc>[27h;<Esc>[<Space>r;
```

ctermfg={color-nr} ctermfg E421
ctermbg={color-nr} ctermbg

The {color-nr} argument is a color number. Its range is zero to (not including) the number of tui-colors available.
The actual color with this number depends on the type of terminal and its settings. Sometimes the color also depends on the settings of "cterm". For example, on some systems "cterm=bold ctermfg=3" gives another color, on others you just get color 3.

The following (case-insensitive) names are recognized:

cterm-colors

NR-16	NR-8	COLOR NAME
0	0	Black
1	4	DarkBlue
2	2	DarkGreen
3	6	DarkCyan
4	1	DarkRed
5	5	DarkMagenta
6	3	Brown, DarkYellow
7	7	LightGray, LightGrey, Gray, Grey
8	0*	DarkGray, DarkGrey
9	4*	Blue, LightBlue
10	2*	Green, LightGreen
11	6*	Cyan, LightCyan
12	1*	Red, LightRed
13	5*	Magenta, LightMagenta
14	3*	Yellow, LightYellow
15	7*	White

The number under "NR-16" is used for 16-color terminals ('t_Co' greater than or equal to 16). The number under "NR-8" is used for 8-color terminals ('t_Co' less than 16). The "*" indicates that the bold attribute is set for ctermfg. In many 8-color terminals (e.g., "linux"), this causes the bright colors to appear. This doesn't work for background colors! Without the "*" the bold attribute is removed. If you want to set the bold attribute in a different way, put a "cterm=" argument AFTER the "ctermfg=" or "ctermbg=" argument. Or use a number instead of a color name.

Note that for 16 color ansi style terminals (including xterms), the
numbers in the NR-8 column is used. Here "*" means "add 8" so that
Blue is 12, DarkGray is 8 etc.

Note that for some color terminals these names may result in the wrong
colors!

You can also use "NONE" to remove the color.

:hi-normal-cterm

When setting the "ctermfg" or "ctermbg" colors for the Normal group,
these will become the colors used for the non-highlighted text.
Example:

```
:highlight Normal ctermfg=grey ctermbg=darkblue
```

When setting the "ctermbg" color for the Normal group, the
'background' option will be adjusted automatically, under the
condition that the color is recognized and 'background' was not set
explicitly. This causes the highlight groups that depend on
'background' to change! This means you should set the colors for
Normal first, before setting other colors.
When a color scheme is being used, changing 'background' causes it to
be reloaded, which may reset all colors (including Normal). First
delete the "g:colors_name" variable when you don't want this.

When you have set "ctermfg" or "ctermbg" for the Normal group, Vim
needs to reset the color when exiting. This is done with the
"orig_pair" terminfo entry.
E419 E420
When Vim knows the normal foreground and background colors, "fg" and
"bg" can be used as color names. This only works after setting the
colors for the Normal group and for the MS-Windows console. Example,
for reverse video:

```
:highlight Visual ctermfg=bg ctermbg=fg
```

Note that the colors are used that are valid at the moment this
command are given. If the Normal group colors are changed later, the
"fg" and "bg" colors will not be adjusted.

1. GUI highlight arguments

gui={attr-list} highlight-gui

These give the attributes to use in the GUI mode.
See attr-list for a description.
Note that "bold" can be used here and by using a bold font. They
have the same effect.
Note that the attributes are ignored for the "Normal" group.

font={font-name} highlight-font

font-name is the name of a font, as it is used on the system Vim
runs on. For X11 this is a complicated name, for example:

```
font=-misc-fixed-bold-r-normal--14-130-75-75-c-70-iso8859-1
```

The font-name "NONE" can be used to revert to the default font.
When setting the font for the "Normal" group, this becomes the default
font (until the 'guifont' option is changed; the last one set is
used).
The following only works with Motif not with other GUIs:
When setting the font for the "Menu" group, the menus will be changed.
When setting the font for the "Tooltip" group, the tooltips will be
changed.
All fonts used, except for Menu and Tooltip, should be of the same
character size as the default font! Otherwise redrawing problems will
occur.
To use a font name with an embedded space or other special character,
put it in single quotes. The single quote cannot be used then.
Example:

```
:hi comment font='Monospace 10'
```

guifg={color-name} guifg

guibg={color-name} guibg

guisp={color-name} guisp

These give the foreground (guifg), background (guibg) and special
(guisp) color to use in the GUI. "guisp" is used for various
underlines.
There are a few special names:

NONE	no color (transparent)
bg	use normal background color
background	use normal background color
fg	use normal foreground color
foreground	use normal foreground color

To use a color name with an embedded space or other special character,
put it in single quotes. The single quote cannot be used then.
Example:

```
:hi comment guifg='salmon pink'
```

gui-colors

Suggested color names (these are available on most systems):

Red	LightRed	DarkRed	
Green	LightGreen	DarkGreen	SeaGreen
Blue	LightBlue	DarkBlue	SlateBlue
Cyan	LightCyan	DarkCyan	
Magenta	LightMagenta	DarkMagenta	
Yellow	LightYellow	Brown	DarkYellow
Gray	LightGray	DarkGray	
Black	White		
Orange	Purple	Violet	

Colors which define Nvim's default color scheme:

NvimDarkBlue	NvimLightBlue
NvimDarkCyan	NvimLightCyan
NvimDarkGray1	NvimLightGray1
NvimDarkGray2	NvimLightGray2
NvimDarkGray3	NvimLightGray3
NvimDarkGray4	NvimLightGray4
NvimDarkGreen	NvimLightGreen
NvimDarkMagenta	NvimLightMagenta
NvimDarkRed	NvimLightRed
NvimDarkYellow	NvimLightYellow

You can also specify a color by its RGB (red, green, blue) values.
The format is "#rrggbb", where
        "rr"   is the Red value
        "gg"   is the Green value
        "bb"   is the Blue value
All values are hexadecimal, range from "00" to "ff". Examples:

```
:highlight Comment guifg=#11f0c3 guibg=#ff00ff
```

blend={integer} highlight-blend opacity

Override the blend level for a highlight group within the popupmenu
or floating windows. Only takes effect if 'pumblend' or 'winblend'
is set for the menu or window. See the help at the respective option.

See also the "blend" flag of nvim_buf_set_extmark().

highlight-groups highlight-default

These are the builtin highlighting groups. Note that the highlighting depends
on the value of 'background'. You can see the current settings with the
":highlight" command.

hl-ColorColumn

ColorColumn Used for the columns set with 'colorcolumn'.

hl-Conceal

Conceal Placeholder characters substituted for concealed
text (see 'conceallevel').

hl-CurSearch

CurSearch Current match for the last search pattern (see 'hlsearch').
Note: This is correct after a search, but may get outdated if
changes are made or the screen is redrawn.

hl-Cursor hl-lCursor

Cursor Character under the cursor.
lCursor Character under the cursor when language-mapping
is used (see 'guicursor').

hl-CursorIM

CursorIM Like Cursor, but used when in IME mode. CursorIM

hl-CursorColumn

CursorColumn Screen-column at the cursor, when 'cursorcolumn' is set.

hl-CursorLine

CursorLine Screen-line at the cursor, when 'cursorline' is set.
Low-priority if foreground (ctermfg OR guifg) is not set.

hl-Directory

Directory Directory names (and other special names in listings).

hl-DiffAdd

DiffAdd Diff mode: Added line. diff.txt

hl-DiffChange

DiffChange Diff mode: Changed line. diff.txt

hl-DiffDelete

DiffDelete Diff mode: Deleted line. diff.txt

hl-DiffText

DiffText Diff mode: Changed text within a changed line. diff.txt

hl-DiffTextAdd

DiffTextAdd Diff mode: Added text within a changed line. Linked to hl-DiffText by default. diff.txt

hl-EndOfBuffer

EndOfBuffer Filler lines (~) after the last line in the buffer. By default, this is highlighted like hl-NonText.

hl-TermCursor

TermCursor Cursor in a focused terminal.

hl-OkMsg

OkMsg Success messages.

hl-WarningMsg

WarningMsg Warning messages.

hl-ErrorMsg

ErrorMsg Error messages.

hl-StderrMsg

StderrMsg Messages in stderr from shell commands.

hl-StdoutMsg

StdoutMsg Messages in stdout from shell commands.

hl-WinSeparator

WinSeparator Separators between window splits.

hl-Folded

Folded Line used for closed folds.

hl-FoldColumn

FoldColumn 'foldcolumn'

hl-SignColumn

SignColumn Column where signs are displayed.

hl-IncSearch

IncSearch 'incsearch' highlighting; also used for the text replaced with ":s///c".

hl-Substitute

Substitute :substitute replacement text highlighting.

hl-LineNr

LineNr Line number for ":number" and ":#" commands, and when 'number' or 'relativenumber' option is set.

hl-LineNrAbove

LineNrAbove Line number for when the 'relativenumber' option is set, above the cursor line.

hl-LineNrBelow

LineNrBelow Line number for when the 'relativenumber' option is set, below the cursor line.

hl-CursorLineNr

CursorLineNr Like LineNr when 'cursorline' is set and 'cursorlineopt' contains "number" or is "both", for the cursor line.

hl-CursorLineFold

CursorLineFold Like FoldColumn when 'cursorline' is set for the cursor line.

hl-CursorLineSign

CursorLineSign Like SignColumn when 'cursorline' is set for the cursor line.

hl-MatchParen

MatchParen Character under the cursor or just before it, if it is a paired bracket, and its match. pi_paren.txt

hl-MCursor

MCursor multicursor cursor.

hl-MCursorVisual

MCursorVisual multicursor Visual selection.

hl-ModeMsg

ModeMsg 'showmode' message (e.g., "-- INSERT --").

hl-MsgArea

MsgArea Area for messages and command-line, see also 'cmdheight'.

hl-MsgSeparator

MsgSeparator Separator for scrolled messages msgsep.

hl-MoreMsg

MoreMsg more-prompt

hl-NonText

NonText '@' at the end of the window, characters from 'showbreak' and other characters that do not really exist in the text (e.g., ">" displayed when a double-wide character doesn't fit at the end of the line). See also hl-EndOfBuffer.

hl-Normal

Normal Normal text.

hl-NormalFloat

NormalFloat Normal text in floating windows.

hl-FloatBorder

FloatBorder Border of floating windows.

hl-FloatShadow

FloatShadow Blended areas when border is "shadow".

hl-FloatShadowThrough

FloatShadowThrough Shadow corners when border is "shadow".

hl-FloatTitle

FloatTitle Title of floating windows.

hl-FloatFooter

FloatFooter Footer of floating windows.

hl-NormalNC

NormalNC Normal text in non-current windows.

hl-Pmenu

Pmenu Popup menu: Normal item.

hl-PmenuSel

PmenuSel Popup menu: Selected item. Combined with hl-Pmenu.

hl-PmenuKind

PmenuKind Popup menu: Normal item "kind".

hl-PmenuKindSel

PmenuKindSel Popup menu: Selected item "kind".

hl-PmenuExtra

PmenuExtra Popup menu: Normal item "extra text".

hl-PmenuExtraSel

PmenuExtraSel Popup menu: Selected item "extra text".

hl-PmenuSbar

PmenuSbar Popup menu: Scrollbar.

hl-PmenuThumb

PmenuThumb Popup menu: Thumb of the scrollbar.

hl-PmenuMatch

PmenuMatch Popup menu: Matched text in normal item. Combined with hl-Pmenu.

hl-PmenuMatchSel

PmenuMatchSel Popup menu: Matched text in selected item. Combined with hl-PmenuMatch and hl-PmenuSel.

hl-PmenuBorder

PmenuBorder Popup menu: border of popup menu.

hl-PmenuShadow

PmenuShadow Popup menu: blended areas when 'pumborder' is "shadow".

hl-PmenuShadowThrough

PmenuShadowThrough Popup menu: shadow corners when 'pumborder' is "shadow".

hl-ComplMatchIns

ComplMatchIns Matched text of the currently inserted completion.

hl-PreInsert

PreInsert Text inserted when "preinsert" is in 'completeopt'.

hl-ComplHint

ComplHint Virtual text of the currently selected completion.

hl-ComplHintMore

ComplHintMore The additional information of the virtual text.

hl-Question

Question hit-enter prompt and yes/no questions.

hl-QuickFixLine

QuickFixLine Current quickfix item in the quickfix window. Combined with

hl-CursorLine when the cursor is there.

hl-Search

Search Last search pattern highlighting (see 'hlsearch').
Also used for similar items that need to stand out.

hl-SnippetTabstop

SnippetTabstop Tabstops in snippets. vim.snippet

hl-SnippetTabstopActive

SnippetTabstopActive
The currently active tabstop. vim.snippet

hl-SpecialKey

SpecialKey Unprintable characters: Text displayed differently from what
it really is. But not 'listchars' whitespace. hl-Whitespace

hl-SpellBad

SpellBad Word that is not recognized by the spellchecker. spell
Combined with the highlighting used otherwise.

hl-SpellCap

SpellCap Word that should start with a capital. spell
Combined with the highlighting used otherwise.

hl-SpellLocal

SpellLocal Word that is recognized by the spellchecker as one that is
used in another region. spell
Combined with the highlighting used otherwise.

hl-SpellRare

SpellRare Word that is recognized by the spellchecker as one that is
hardly ever used. spell
Combined with the highlighting used otherwise.

hl-StatusLine

StatusLine Status line of current window.

hl-StatusLineNC

StatusLineNC Status lines of not-current windows.

hl-StatusLineTerm

StatusLineTerm Status line of terminal window.

hl-StatusLineTermNC

StatusLineTermNC
Status line of non-current terminal windows.

hl-TabLine

TabLine Tabpages line, not active tabpage label.
Combined with hl-TabLineFill.

hl-TabLineFill

TabLineFill Tabpages line, where there are no labels.

hl-TabLineSel

TabLineSel Tabpages line, active tabpage label.
Combined with hl-TabLineFill.

hl-Title

Title Titles for output from ":set all", ":autocmd" etc.

hl-Visual

Visual Visual mode selection.

hl-VisualNOS

VisualNOS Visual mode selection when vim is "Not Owning the Selection".

hl-Whitespace

Whitespace "nbsp", "space", "tab", "multispace", "lead" and "trail"
in 'listchars'.

hl-WildMenu

WildMenu Current match in 'wildmenu' completion.

hl-WinBar

WinBar Window bar of current window.

hl-WinBarNC

WinBarNC Window bar of not-current windows.

hl-User1 hl-User1..9 hl-User9

The 'statusline' syntax allows the use of 9 different highlights in the
statusline and ruler (via 'rulerformat'). The names are User1 to User9.

For the GUI you can use the following groups to set the colors for the menu,
scrollbars and tooltips. They don't have defaults. This doesn't work for the
Win32 GUI. Only three highlight arguments have any effect here: font, guibg,
and guifg.

hl-Menu

Menu Current font, background and foreground colors of the menus.
Also used for the toolbar.
Applicable highlight arguments: font, guibg, guifg.

hl-Scrollbar

Scrollbar Current background and foreground of the main window's
scrollbars.
Applicable highlight arguments: guibg, guifg.

hl-Tooltip

Tooltip Current font, background and foreground of the tooltips.
Applicable highlight arguments: font, guibg, guifg.

14. Linking groups :hi-link :highlight-link E412 E413

When you want to use the same highlighting for several syntax groups, you can do this more easily by linking the groups into one common highlight group, and give the color attributes only for that group.

To set a link:

```
:hi[ghlight][!] [default] link {from-group} {to-group}
```

To remove a link:

```
:hi[ghlight][!] [default] link {from-group} NONE
```

Notes: E414

- If the {from-group} and/or {to-group} doesn't exist, it is created. You don't get an error message for a non-existing group.
- As soon as you use a ":highlight" command for a linked group, the link is removed.
- If there are already highlight settings for the {from-group}, the link is not made, unless the '!' is given. For a ":highlight link" command in a sourced file, you don't get an error message. This can be used to skip links for groups that already have settings.

:hi-default :highlight-default

The [default] argument is used for setting the default highlighting for a group. If highlighting has already been specified for the group the command will be ignored. Also when there is an existing link.

Using [default] is especially useful to overrule the highlighting of a specific syntax file. For example, the C syntax file contains:

```
:highlight default link cComment Comment
```

If you like Question highlighting for C comments, put this in your vimrc file:

```
:highlight link cComment Question
```

Without the "default" in the C syntax file, the highlighting would be overruled when the syntax file is loaded.

To have a link survive :highlight clear, which is useful if you have highlighting for a specific filetype and you want to keep it when selecting another color scheme, put a command like this in the "after/syntax/{filetype}.vim" file:

```
highlight! default link cComment Question
```

15. Cleaning up :syn-clear E391

If you want to clear the syntax stuff for the current buffer, you can use this command:

```
:syntax clear
```

This command should be used when you want to switch off syntax highlighting, or when you want to switch to using another syntax. It's normally not needed in a syntax file itself, because syntax is cleared by the autocommands that load the syntax file.
The command also deletes the "b:current_syntax" variable, since no syntax is loaded after this command.

To clean up specific syntax groups for the current buffer:

```
:syntax clear {group-name} ...
```

This removes all patterns and keywords for {group-name}.

To clean up specific syntax group lists for the current buffer:

```
:syntax clear @{grouplist-name} ...
```

This sets {grouplist-name}'s contents to an empty list.

:syntax-off :syn-off

If you want to disable syntax highlighting for all buffers, you need to remove the autocommands that load the syntax files:

```
:syntax off
```

What this command actually does, is executing the command

```
:source $VIMRUNTIME/syntax/nosyntax.vim
```

See the "nosyntax.vim" file for details. Note that for this to work $VIMRUNTIME must be valid. See $VIMRUNTIME.

:syntax-reset :syn-reset

If you have changed the colors and messed them up, use this command to get the defaults back:

```
:syntax reset
```

It is a bit of a wrong name, since it does not reset any syntax items, it only affects the highlighting.

Note that the syntax colors that you set in your vimrc file will also be reset back to their Vim default.
Note that if you are using a color scheme, the colors defined by the color scheme for syntax highlighting will be lost.

Note that when a color scheme is used, there might be some confusion whether your defined colors are to be used or the colors from the scheme. This depends on the color scheme file. See :colorscheme.

16. Highlighting tags

tag-highlight

If you want to highlight all the tags in your file, you can use the following mappings.

```
        <F11>   -- Generate tags.vim file, and highlight tags.
        <F12>   -- Just highlight tags based on existing tags.vim file.
```

```
:map <F11>  :sp tags<CR>:%s/^\([^       :]*:\)\=\([^    ]*\).*/syntax keyword Tag \2/<CR>:wq! tags.vim<CR>/^<CR><F12>
:map <F12>  :so tags.vim<CR>
```

WARNING: The longer the tags file, the slower this will be, and the more memory Vim will consume.

Only highlighting typedefs, unions and structs can be done too. For this you must use Universal Ctags (https://ctags.io) or Exuberant ctags.

Put these lines in your Makefile:

```
# Make a highlight file for types.  Requires Universal/Exuberant ctags and awk
types: types.vim
types.vim: *.[ch]
        ctags --c-kinds=gstu -o- *.[ch] |\
                awk 'BEGIN{printf("syntax keyword Type\t")}\
                        {printf("%s ", $$1)}END{print ""}' > $@
```

And put these lines in your vimrc:

```
" load the types.vim highlighting file, if it exists
autocmd BufRead,BufNewFile *.[ch] let fname = expand('<afile>:p:h') .. '/types.vim'
autocmd BufRead,BufNewFile *.[ch] if filereadable(fname)
autocmd BufRead,BufNewFile *.[ch]   exe 'so ' .. fname
autocmd BufRead,BufNewFile *.[ch] endif
```

17. Color xterms

xterm-color color-xterm

colortest.vim

To test your color setup, a file has been included in the Vim distribution.
To use it, execute this command:

```
:runtime syntax/colortest.vim
```

Nvim uses 256-color and true-color terminal capabilities wherever possible.

18. When syntax is slow

:synti :syntime

This is aimed at authors of a syntax file.

If your syntax causes redrawing to be slow, here are a few hints on making it faster. To see slowness switch on some features that usually interfere, such as 'relativenumber' and folding.

To find out what patterns are consuming the most time, get an overview with this sequence:

```
:syntime on
[ redraw the text at least once with CTRL-L ]
:syntime report
```

This will display a list of syntax patterns that were used, sorted by the time it took to match them against the text.

:synti[me] on — Start measuring syntax times. This will add some overhead to compute the time spent on syntax pattern matching.

:synti[me] off — Stop measuring syntax times.

:synti[me] clear — Set all the counters to zero, restart measuring.

:synti[me] report — Show the syntax items used since ":syntime on" in the current window. Use a wider display to see more of the output.

The list is sorted by total time. The columns are:

TOTAL	Total time in seconds spent on matching this pattern.
COUNT	Number of times the pattern was used.
MATCH	Number of times the pattern actually matched
SLOWEST	The longest time for one try.
AVERAGE	The average time for one try.
NAME	Name of the syntax item. Note that this is not unique.
PATTERN	The pattern being used.

Pattern matching gets slow when it has to try many alternatives. Try to include as much literal text as possible to reduce the number of ways a pattern does NOT match.

When using the "\@<=" and "\@<!" items, add a maximum size to avoid trying at all positions in the current and previous line. For example, if the item is literal text specify the size of that text (in bytes):

"<\@<=span"	Matches "span" in "<span". This tries matching with "<" in many places.
"<\@1<=span"	Matches the same, but only tries one byte before "span".

Editing with windows in multiple tabpages. tabpage

The commands which have been added to use multiple tabpages are explained here. Additionally, there are explanations for commands that work differently when used in combination with more than one tabpage.

1. Introduction tabpage-intro

A tabpage holds one or more windows. You can easily switch between tab pages, so that you have several collections of windows to work on different things.

Usually you will see a list of labels at the top of the Vim window, one for each tabpage. With the mouse you can click on the label to jump to that tab page. There are other ways to move between tabpages, see below.

Most commands work only in the current tabpage. That includes the CTRL-W commands, :windo, :all and :ball (when not using the :tab modifier).
The commands that are aware of other tabpages than the current one are mentioned below.

Tabpages are also a nice way to edit a buffer temporarily without changing the current window layout. Open a new tabpage, do whatever you want to do and close the tabpage.

tab-ID tabid tabpageid
Each tabpage has an unique identifier which will not change, even after rearranging tabs. nvim_get_current_tabpage() returns the tab-id and nvim_list_tabpages() lists tab-ids in the order they're displayed.

tabpage-number

Tabpages are numbered from left to right starting at 1: this tab "number" is returned by tabpagenr(). Unlike the tab-id, the tab number may change when tabs are opened, closed, or rearranged. nvim_tabpage_get_number() converts a tab-id to a tab number.

2. Commands tabpage-commands

OPENING A NEW TABPAGE:

When starting Vim "vim -p filename ..." opens each file argument in a separate tabpage (up to 'tabpagemax'). See -p

A double click with the mouse in the non-GUI tabpages line opens a new, empty tabpage. It is placed left of the position of the click. The first click may select another tabpage first, causing an extra screen update.

This also works in a few GUI versions, esp. Win32. But only when clicking right of the labels.

In the GUI tabpages line you can use the right mouse button to open menu. tabline-menu.

For the related autocommands see tabnew-autocmd.

:[count]tabe[dit] :tabe :tabedit :tabnew
:[count]tabnew
Open a new tabpage with an empty window, after the current tabpage. If [count] is given the new tabpage appears after the tabpage [count] otherwise the new tabpage will appear after the current one.

```
:tabnew     " opens tabpage after the current one
:.tabnew    " as above
:+tabnew    " opens tabpage after the next tabpage
            " note: it is one further than :tabnew
:-tabnew    " opens tabpage before the current
:0tabnew    " opens tabpage before the first one
:$tabnew    " opens tabpage after the last one
```

:[count]tabe[dit] [++opt] [+cmd] {file}
:[count]tabnew [++opt] [+cmd] {file}
Open a new tabpage and edit {file}, like with :edit.
For [count] see :tabnew above.

:[count]tabf[ind] [++opt] [+cmd] {file} :tabf :tabfind
Open a new tabpage and edit {file} in 'path', like with :find. For [count] see :tabnew above.

:[count]tab {cmd} :tab

Execute {cmd} and when it opens a new window open a new tab page instead. Doesn't work for :diffsplit, :diffpatch, :execute and :normal.
If [count] is given the new tabpage appears after the tab page [count] otherwise the new tabpage will appear after the current one.
Examples:

```
:tab split          " opens current buffer in new tabpage
:tab help gt    " opens tabpage with help for "gt"
:.tab help gt   " as above
:+tab help          " opens tabpage with help after the next
                " tabpage
:-tab help          " opens tabpage with help before the
                " current one
:0tab help          " opens tabpage with help before the
                " first one
:$tab help          " opens tabpage with help after the last
                " one
```

CTRL-W gf Open a new tabpage and edit the file name under the cursor.
           See CTRL-W_gf.

CTRL-W gF Open a new tabpage and edit the file name under the cursor
           and jump to the line number following the file name.
           See CTRL-W_gF.

CLOSING A TABPAGE:

Closing the last window of a tabpage closes the tabpage too, unless there is
only one tabpage.

Using the mouse: If the tabpage line is displayed you can click in the "X" at
the top right to close the current tabpage. A custom 'tabline' may show
something else.

:tabc :tabclose

:tabc[lose][!] Close current tabpage.
           This command fails when:

- There is only one tabpage on the screen. E784

- When 'hidden' is not set, [!] is not used, a buffer has

  changes, and there is no other window on this buffer.
  Changes to the buffer are not written and won't get lost, so
  this is a "safe" command.

```
:tabclose   " close the current tabpage
```

:{count}tabc[lose][!]
:tabc[lose][!] {count}
           Close tabpage {count}. Fails in the same way as :tabclose
           above.

```
:-tabclose          " close the previous tabpage
:+tabclose          " close the next tabpage
:1tabclose          " close the first tabpage
:$tabclose          " close the last tabpage
:tabclose -2    " close the 2nd previous tabpage
:tabclose +         " close the next tabpage
:tabclose 3         " close the third tabpage
:tabclose $         " close the last tabpage
:tabclose #     " close the last accessed tabpage
```

When a tabpage is closed the next tabpage will become the current one. This
behaviour can be customized using the 'tabclose' option.

:tabo :tabonly

:tabo[nly][!]   Close all other tabpages.
           When the 'hidden' option is set, all buffers in closed windows
           become hidden.
           When 'hidden' is not set, and the 'autowrite' option is set,
           modified buffers are written. Otherwise, windows that have
           buffers that are modified are not removed, unless the [!] is
           given, then they become hidden. But modified buffers are
           never abandoned, so changes cannot get lost.

```
:tabonly " close all tabpages except the current one
```

:tabo[nly][!] {count}
           Close all tabpages except {count} one.

```
:.tabonly           " as above
:-tabonly           " close all tabpages except the previous
                " one
:+tabonly           " close all tabpages except the next one
:1tabonly           " close all tabpages except the first one
:$tabonly           " close all tabpages except the last one
:tabonly -          " close all tabpages except the previous
                " one
:tabonly +2     " close all tabpages except the two next
                " one
:tabonly 1          " close all tabpages except the first one
:tabonly $          " close all tabpages except the last one
:tabonly #          " close all tabpages except the last
                " accessed one
```

SWITCHING TO ANOTHER TABPAGE:

Using the mouse: If the tabpage line is displayed you can click in a tabpage label to switch to that tabpage. Click where there is no label to go to the next tabpage. 'tabline'

:tabn[ext] :tabn :tabnext gt
<C-PageDown> CTRL-<PageDown> <C-PageDown>
gt i_CTRL-<PageDown> i_<C-PageDown>
Go to the next tabpage. Wraps around from the last to the first one.

:{count}tabn[ext]
:tabn[ext] {count}
Go to tabpage {count}. The first tabpage has number one.

```
:-tabnext       " go to the previous tabpage
:+tabnext       " go to the next tabpage
:+2tabnext      " go to the two next tabpage
:1tabnext       " go to the first tabpage
:$tabnext       " go to the last tabpage
:tabnext $      " as above
:tabnext #      " go to the last accessed tabpage
:tabnext -      " go to the previous tabpage
:tabnext -1     " as above
:tabnext +      " go to the next tabpage
:tabnext +1     " as above
```

{count}<C-PageDown>
{count}gt Go to tabpage {count}. The first tabpage has number one.

:tabp[revious] :tabp :tabprevious gT :tabN
:tabN[ext] :tabNext CTRL-<PageUp>
<C-PageUp> <C-PageUp> i_CTRL-<PageUp> i_<C-PageUp>
gT Go to the previous tabpage. Wraps around from the first one to the last one.

:tabp[revious] {count}
:tabN[ext] {count}
{count}<C-PageUp>
{count}gT Go {count} tabpages back. Wraps around from the first one to the last one. Note that the use of {count} is different from :tabnext, where it is used as the tabpage number.

:tabr[ewind] :tabfir :tabfirst :tabr :tabrewind
:tabfir[st] Go to the first tabpage.

:tabl :tablast
:tabl[ast] Go to the last tabpage.

<C-Tab> CTRL-<Tab> <C-Tab>
g<Tab> g<Tab> CTRL-W_g<Tab>
CTRL-W g<Tab> Go to the last accessed tabpage.

Other commands:

:tabs

:tabs List the tabpages and the windows they contain.
Shows a ">" for the current window.
Shows a "+" for modified buffers.
For example:

```
Tabpage 1
+ tabpage.txt
ex_docmd.c
Tabpage 2
>   main.c
```

REORDERING TABPAGES:

:tabm[ove] [N] :tabm :tabmove
:[N]tabm[ove]
Move the current tabpage to after tabpage N. Use zero to make the current tabpage the first one. N is counted before the move, thus if the second tabpage is the current one, :tabmove 1 and :tabmove 2 have no effect.
Without N the tabpage is made the last one.

```
:.tabmove       " do nothing
:-tabmove       " move the tabpage to the left
:+tabmove       " move the tabpage to the right
:0tabmove       " move the tabpage to the first
:tabmove 0      " as above
:tabmove        " move the tabpage to the last
:$tabmove       " as above
:tabmove $      " as above
:tabmove #      " move the tabpage after the last accessed
            " tabpage
```

```
:tabm[ove] +[N]
:tabm[ove] -[N]
                Move the current tabpage N places to the right (with +) or to
                the left (with -).
```

```
:tabmove -      " move the tabpage to the left
:tabmove -1     " as above
:tabmove +      " move the tabpage to the right
:tabmove +1     " as above
```

Note that although it is possible to move a tabpage behind the N-th one by using :Ntabmove. And move it by N places by using :+Ntabmove. For clarification what +N means in this context see [range].

LOOPING OVER TABPAGES:

:tabd :tabdo

```
:[range]tabd[o] {cmd}
                Execute {cmd} in each tabpage or, if [range] is given, only
                in tabpages which tabpage number is in the [range]. It works
                like doing this:
```

```
:tabfirst
:{cmd}
:tabnext
:{cmd}
etc.
```

```
                This only operates in the current window of each tabpage.
                When an error is detected on one tabpage, further tabpages
                will not be visited.
                The last tabpage (or where an error occurred) becomes the
                current tabpage.
                {cmd} can contain '|' to concatenate several commands.
                {cmd} must not open or close tabpages or reorder them.
                Also see :windo, :argdo, :bufdo, :cdo, :ldo, :cfdo
                and :lfdo.
```

3. Other items

tabpage-other

tabline-menu

The GUI tabpages line has a popup menu. It is accessed with a right click. The entries are:

Close	Close the tabpage under the mouse pointer. The current one if there is no label under the mouse pointer.
New Tab	Open a tabpage, editing an empty buffer. It appears to the left of the mouse pointer.
Open Tab...	Like "New Tab" and additionally use a file selector to select a file to edit.

Diff mode works per tabpage. You can see the diffs between several files within one tabpage. Other tabpages can show differences between other files.

Variables local to a tabpage start with "t:". tabpage-variable

Currently there is only one option local to a tabpage: 'cmdheight'.

tabnew-autocmd

The TabLeave and TabEnter autocommand events can be used to do something when switching from one tabpage to another. The exact order depends on what you are doing. When creating a new tabpage this works as if you create a new window on the same buffer and then edit another buffer. Thus ":tabnew" triggers:

WinLeave	leave current window
TabLeave	leave current tabpage
WinEnter	enter window in new tabpage
TabEnter	enter new tabpage
BufLeave	leave current buffer
BufEnter	enter new empty buffer

When switching to another tabpage the order is:

- BufLeave
- WinLeave
- TabLeave
- WinEnter

TabEnter
BufEnter

When entering a new tabpage (:tabnew), TabNew is triggered before TabEnter and after WinEnter.

4. Setting 'tabline' setting-tabline

The 'tabline' option specifies what the line with tabpages labels looks like. It is only used when there is no GUI tab line.

You can use the 'showtabline' option to specify when you want the line with tabpage labels to appear: never, when there is more than one tabpage or always.

The highlighting of the tabpages line is set with the groups TabLine TabLineSel and TabLineFill. hl-TabLine hl-TabLineSel hl-TabLineFill

A "+" will be shown for a tabpage that has a modified window. The number of windows in a tabpage is also shown. Thus "3+" means three windows and one of them has a modified buffer.

The 'tabline' option allows you to define your preferred way to tabpages labels. This isn't easy, thus an example will be given here.

For basics see the 'statusline' option. The same items can be used in the 'tabline' option. Additionally, the tabpagebuflist(), tabpagenr() and tabpagewinnr() functions are useful.

Since the number of tab labels will vary, you need to use an expression for the whole option. Something like:

```
:set tabline=%!MyTabLine()
```

Then define the MyTabLine() function to list all the tabpages labels. A convenient method is to split it in two parts: First go over all the tab pages and define labels for them. Then get the label for each tabpage.

```
function MyTabLine()
  let s = ''
  for i in range(tabpagenr('$'))
    " select the highlighting
    if i + 1 == tabpagenr()
      let s ..= '%#TabLineSel#'
    else
      let s ..= '%#TabLine#'
    endif

    " set the tabpage number (for mouse clicks)
    let s ..= '%' .. (i + 1) .. 'T'

    " the label is made by MyTabLabel()
    let s ..= ' %{MyTabLabel(' .. (i + 1) .. ')} '
  endfor

  " after the last tabpage fill with TabLineFill and reset tabpage nr
  let s ..= '%#TabLineFill#%T'

  " right-align the label to close the current tabpage
  if tabpagenr('$') > 1
    let s ..= '%=%#TabLine#%999Xclose'
  endif

  return s
endfunction
```

Now the MyTabLabel() function is called for each tabpage to get its label.

```
function MyTabLabel(n)
  let buflist = tabpagebuflist(a:n)
  let winnr = tabpagewinnr(a:n)
  return bufname(buflist[winnr - 1])
endfunction
```

This is just a simplistic example that results in a tabpages line that resembles the default, but without adding a + for a modified buffer or truncating the names. You will want to reduce the width of labels in a clever way when there is not enough room. Check the 'columns' option for the space available.

5. Setting 'guitablabel' setting-guitablabel

When the GUI tabpages line is displayed, 'guitablabel' can be used to specify the label to display for each tabpage. Unlike 'tabline', which specifies the whole tabpages line at once, 'guitablabel' is used for each label separately.

'guitabtooltip' is very similar and is used for the tooltip of the same label. This only appears when the mouse pointer hovers over the label, thus it usually is longer. Only supported on some systems though.

See the 'statusline' option for the format of the value.

The "%N" item can be used for the current tabpage number. The v:lnum
variable is also set to this number when the option is evaluated.
The items that use a file name refer to the current window of the tabpage.

Note that syntax highlighting is not used for the option. The %T and %X
items are also ignored.

A simple example that puts the tabpage number and the buffer name in the
label:

```
:set guitablabel=%N\ %f
```

An example that resembles the default 'guitablabel': Show the number of
windows in the tabpage and a '+' if there is a modified buffer:

```
function GuiTabLabel()
  let label = ''
  let bufnrlist = tabpagebuflist(v:lnum)

  " Add '+' if one of the buffers in the tabpage is modified
  for bufnr in bufnrlist
    if getbufvar(bufnr, "&modified")
      let label = '+'
      break
    endif
  endfor

  " Append the number of windows in the tabpage if more than one
  let wincount = tabpagewinnr(v:lnum, '$')
  if wincount > 1
    let label ..= wincount
  endif
  if label != ''
    let label ..= ' '
  endif

  " Append the buffer name
  return label .. bufname(bufnrlist[tabpagewinnr(v:lnum) - 1])
endfunction

set guitablabel=%{GuiTabLabel()}
```

Note that the function must be defined before setting the option, otherwise
you get an error message for the function not being known.

If you want to fall back to the default label, return an empty string.

If you want to show something specific for a tabpage, you might want to use a
tabpage local variable. t:var

Tags and special searches

See section 29.1 of the user manual for an introduction.

1. Jump to a tag

tag-commands

tag tags

A tag is an identifier that appears in a "tags" file. It is a sort of label that can be jumped to. For example: In C programs each function name can be used as a tag. The "tags" file has to be generated by a program like ctags, before the tag commands can be used.

With the ":tag" command the cursor will be positioned on the tag. With the CTRL-] command, the keyword on which the cursor is standing is used as the tag. If the cursor is not on a keyword, the first keyword to the right of the cursor is used.

The ":tag" command works very well for C programs. If you see a call to a function and wonder what that function does, position the cursor inside of the function name and hit CTRL-]. This will bring you to the function definition. An easy way back is with the CTRL-T command. Also read about the tag stack below.

:ta :tag E426 E429

:[count]ta[g][!] {name}
Jump to the definition of {name}, using the information in the tags file(s). Put {name} in the tag stack. See tag-! for [!].
{name} can be a regexp pattern, see tag-regexp.
When there are several matching tags for {name}, jump to the [count] one. When [count] is omitted the first one is jumped to. See tag-matchlist for jumping to other matching tags.

g<LeftMouse> g<LeftMouse> CTRL-]

CTRL-]
Jump to the definition of the keyword under the cursor. Same as ":tag {name}", where {name} is the keyword under or after cursor.
When there are several matching tags for {name}, jump to the [count] one. When no [count] is given the first one is jumped to. See tag-matchlist for jumping to other matching tags.

v CTRL-]

{Visual}CTRL-]
Same as ":tag {name}", where {name} is the text that is highlighted.

telnet-CTRL-]

CTRL-] is the default telnet escape key. When you type CTRL-] to jump to a tag, you will get the telnet prompt instead. Most versions of telnet allow changing or disabling the default escape key. See the telnet man page. You can telnet -E {Hostname} to disable the escape character, or
telnet -e {EscapeCharacter} {Hostname} to specify another escape character.
If possible, try to use "ssh" instead of "telnet" to avoid this problem.

tag-priority

When there are multiple matches for a tag, this priority is used:

1. "FSC" A full matching static tag for the current file.
2. "F C" A full matching global tag for the current file.
3. "F " A full matching global tag for another file.
4. "FS " A full matching static tag for another file.
5. " SC" An ignore-case matching static tag for the current file.
6. " C" An ignore-case matching global tag for the current file.
7. " " An ignore-case matching global tag for another file.
8. " S " An ignore-case matching static tag for another file.

Note that when the current file changes, the priority list is mostly not changed, to avoid confusion when using ":tnext". It is changed when using ":tag {name}".

The ignore-case matches are not found for a ":tag" command when:

- 'tagcase' is "followic" and the 'ignorecase' option is off
- 'tagcase' is "followscs" and the 'ignorecase' option is off and the

'smartcase' option is off or the pattern contains an upper case character.
- 'tagcase' is "match"

- 'tagcase' is "smart" and the pattern contains an upper case character.

The ignore-case matches are found when:
- a pattern is used (starting with a "/")

- for ":tselect"

- when 'tagcase' is "followic" and 'ignorecase' is on

- when 'tagcase' is "followscs" and 'ignorecase' is on or the 'smartcase'

option is on and the pattern does not contain an upper case character
- when 'tagcase' is "ignore"

- when 'tagcase' is "smart" and the pattern does not contain an upper case

character

Note that using ignore-case tag searching disables binary searching in the tags file, which causes a slowdown. This can be avoided by fold-case sorting the tag file. See the 'tagbsearch' option for an explanation.

2. Tag stack

tag-stack tagstack E425

On the tag stack is remembered which tags you jumped to, and from where. Tags are only pushed onto the stack when the 'tagstack' option is set.

g<RightMouse>

g<RightMouse>

<C-RightMouse>

<C-RightMouse> CTRL-T

CTRL-T Jump to [count] older entry in the tag stack (default 1).

:po :pop E555 E556

:[count]po[p][!] Jump to [count] older entry in tag stack (default 1). See tag-! for [!].

:[count]ta[g][!] Jump to [count] newer entry in tag stack (default 1). See tag-! for [!].

:tags

:tags Show the contents of the tag stack. The active entry is marked with a '>'.

The output of ":tags" looks like this:

```
   # TO tag      FROM line  in file/text
   1  1 main             1  harddisk2:text/vim/test
 > 2  2 FuncA           58  i = FuncA(10);
   3  1 FuncC          357  harddisk2:text/vim/src/amiga.c
```

This list shows the tags that you jumped to and the cursor position before that jump. The older tags are at the top, the newer at the bottom.

The '>' points to the active entry. This is the tag that will be used by the next ":tag" command. The CTRL-T and ":pop" command will use the position above the active entry.

Below the "TO" is the number of the current match in the match list. Note that this doesn't change when using ":pop" or ":tag".

The line number and file name are remembered to be able to get back to where you were before the tag command. The line number will be correct, also when deleting/inserting lines, unless this was done by another program (e.g. another instance of Vim).

For the current file, the "file/text" column shows the text at the position. An indent is removed and a long line is truncated to fit in the window.

You can jump to previously used tags with several commands. Some examples:

```
        ":pop" or CTRL-T        to position before previous tag
        {count}CTRL-T           to position before {count} older tag
        ":tag"                  to newer tag
        ":0tag"                 to last used tag
```

The most obvious way to use this is while browsing through the call graph of a program. Consider the following call graph:

```
        main  --->  FuncA  --->  FuncC
              --->  FuncB
```

(Explanation: main calls FuncA and FuncB; FuncA calls FuncC).
You can get from main to FuncA by using CTRL-] on the call to FuncA. Then you can CTRL-] to get to FuncC. If you now want to go back to main you can use CTRL-T twice. Then you can CTRL-] to FuncB.

If you issue a ":ta {name}" or CTRL-] command, this tag is inserted at the current position in the stack. If the stack was full (it can hold up to 20 entries), the oldest entry is deleted and the older entries shift one position up (their index number is decremented by one). If the last used entry was not at the bottom, the entries below the last used one are deleted. This means that an old branch in the call graph is lost. After the commands explained above the tag stack will look like this:

```
   # TO tag     FROM line  in file/text
   1  1 main            1  harddisk2:text/vim/test
   2  1 FuncB          59  harddisk2:text/vim/src/main.c
```

The gettagstack() function returns the tag stack of a specified window. The settagstack() function modifies the tag stack of a window.

tagstack-examples

Write to the tag stack just like :tag but with a user-defined jumper#jump_to_tag function:

```
" Store where we're jumping from before we jump.
let tag = expand('<cword>')
let pos = [bufnr()] + getcurpos()[1:]
let item = {'bufnr': pos[0], 'from': pos, 'tagname': tag}
if jumper#jump_to_tag(tag)
        " Jump was successful, write previous location to tag stack.
        let winid = win_getid()
        let stack = gettagstack(winid)
        let stack['items'] = [item]
        call settagstack(winid, stack, 't')
endif
```

Set current index of the tag stack to 4:

```
call settagstack(1005, {'curidx' : 4})
```

Push a new item onto the tag stack:

```
let pos = [bufnr('myfile.txt'), 10, 1, 0]
let newtag = [{'tagname' : 'mytag', 'from' : pos}]
call settagstack(2, {'items' : newtag}, 'a')
```

E73

When you try to use the tag stack while it doesn't contain anything you will get an error message.

3. Tag match list

tag-matchlist E427 E428

When there are several matching tags, these commands can be used to jump between them. Note that these commands don't change the tag stack, they keep the same entry.

:ts :tselect

:ts[elect][!] [name] List the tags that match [name], using the information in the tags file(s).
When [name] is not given, the last tag name from the tag stack is used.
See tag-! for [!].
With a '>' in the first column is indicated which is the current position in the list (if there is one).
[name] can be a regexp pattern, see tag-regexp.
See tag-priority for the priorities used in the listing.
Example output:

```
  # pri kind tag               file
  1 F   f    mch_delay         os_amiga.c
               mch_delay(msec, ignoreinput)
> 2 F   f    mch_delay         os_msdos.c
               mch_delay(msec, ignoreinput)
  3 F   f    mch_delay         os_unix.c
               mch_delay(msec, ignoreinput)
Type number and <Enter> (empty cancels):
```

See tag-priority for the "pri" column. Note that this depends on the current file, thus using ":tselect xxx" can produce different results.
The "kind" column gives the kind of tag, if this was included in the tags file.
The "info" column shows information that could be found in the tags file. It depends on the program that produced the tags file.
When the list is long, you may get the more-prompt. If you already see the tag you want to use, you can type 'q' and enter the number.

:sts :stselect

:sts[elect][!] [name] Does ":tselect[!] [name]" and splits the window for the selected tag.

g]

g] Like CTRL-], but use ":tselect" instead of ":tag".

v_g]

{Visual}g] Same as "g]", but use the highlighted text as the identifier.

:tj :tjump

:tj[ump][!] [name] Like ":tselect", but jump to the tag directly when there is only one match.

:stj :stjump

:stj[ump][!] [name] Does ":tjump[!] [name]" and splits the window for the selected tag.

g_CTRL-]

g CTRL-] Like CTRL-], but use ":tjump" instead of ":tag".

v_g_CTRL-]

{Visual}g CTRL-] Same as "g CTRL-]", but use the highlighted text as the identifier.

:tn :tnext

:[count]tn[ext][!] Jump to [count] next matching tag (default 1). See tag-! for [!].

]t

]t Mapped to :tnext. default-mappings

:tp :tprevious

:[count]tp[revious][!] Jump to [count] previous matching tag (default 1). See tag-! for [!].

[t

[t Mapped to :tprevious. default-mappings

:tN :tNext

:[count]tN[ext][!] Same as ":tprevious".

:tr :trewind

:[count]tr[ewind][!] Jump to first matching tag. If [count] is given, jump to [count]th matching tag. See tag-! for [!].

[T

[T Mapped to :trewind. default-mappings

:tf :tfirst

:[count]tf[irst][!] Same as ":trewind".

:tl :tlast

:tl[ast][!] Jump to last matching tag. See tag-! for [!].

]T

]T Mapped to :tlast. default-mappings

:lt :ltag

:lt[ag][!] [name] Jump to tag [name] and add the matching tags to a new location list for the current window. [name] can be a regexp pattern, see tag-regexp. When [name] is not given, the last tag name from the tag stack is used. The search pattern to locate the tag line is prefixed with "\V" to escape all the special characters (very nomagic). The location list showing the matching tags is independent of the tag stack. See tag-! for [!].

When there is no other message, Vim shows which matching tag has been jumped to, and the number of matching tags:

```
tag 1 of 3 or more
```

The " or more" is used to indicate that Vim didn't try all the tags files yet. When using ":tnext" a few times, or with ":tlast", more matches may be found.

When you didn't see this message because of some other message, or you just want to know where you are, this command will show it again (and jump to the same tag as last time):

```
:0tn
```

tag-skip-file

When a matching tag is found for which the file doesn't exist, this match is skipped and the next matching tag is used. Vim reports this, to notify you of missing files. When the end of the list of matches has been reached, an error message is given.

tag-preview

The tag match list can also be used in the preview window. The commands are the same as above, with a "p" prepended.

:pts :ptselect

:pts[elect][!] [name] Does ":tselect[!] [name]" and shows the new tag in a

"Preview" window. See :ptag for more info.

:ptj :ptjump
:ptj[ump][!] [name] Does ":tjump[!] [name]" and shows the new tag in a "Preview" window. See :ptag for more info.

:ptn :ptnext
:[count]ptn[ext][!] ":tnext" in the preview window. See :ptag.

]_CTRL-T

]_CTRL-T Mapped to :ptnext. default-mappings

:ptp :ptprevious
:[count]ptp[revious][!] ":tprevious" in the preview window. See :ptag.

[_CTRL-T

[_CTRL-T Mapped to :ptprevious. default-mappings

:ptN :ptNext
:[count]ptN[ext][!] Same as ":ptprevious".

:ptr :ptrewind
:[count]ptr[ewind][!] ":trewind" in the preview window. See :ptag.

:ptf :ptfirst
:[count]ptf[irst][!] Same as ":ptrewind".

:ptl :ptlast
:ptl[ast][!] ":tlast" in the preview window. See :ptag.

4. Tags details tag-details

static-tag

A static tag is a tag that is defined for a specific file. In a C program this could be a static function.

In Vi jumping to a tag sets the current search pattern. This means that the "n" command after jumping to a tag does not search for the same pattern that it did before jumping to the tag. Vim does not do this as we consider it to be a bug. If you really want the old Vi behavior, set the 't' flag in 'cpoptions'.

tag-binary-search

Vim uses binary searching in the tags file to find the desired tag quickly. But this only works if the tags file was sorted on ASCII byte value. Therefore, if no match was found, another try is done with a linear search. If you only want the linear search, reset the 'tagbsearch' option. Or better: Sort the tags file!

Note that the binary searching is disabled when not looking for a tag with a specific name. This happens when ignoring case and when a regular expression is used that doesn't start with a fixed string. Tag searching can be a lot slower then. The former can be avoided by case-fold sorting the tags file. See 'tagbsearch' for details.

tag-regexp

The ":tag" and ":tselect" commands accept a regular expression argument. See pattern for the special characters that can be used.
When the argument starts with '/', it is used as a pattern. If the argument does not start with '/', it is taken literally, as a full tag name.
Examples:

```
:tag main
```

jumps to the tag "main" that has the highest priority.

```
:tag /^get
```

jumps to the tag that starts with "get" and has the highest priority.

```
:tag /norm
```

lists all the tags that contain "norm", including "id_norm".
When the argument both exists literally, and match when used as a regexp, a literal match has a higher priority. For example, ":tag /open" matches "open" before "open_file" and "file_open".
When using a pattern case is ignored. If you want to match case use "\C" in the pattern.

tag-!

If the tag is in the current file this will always work. Otherwise the performed actions depend on whether the current file was changed, whether a ! is added to the command and on the 'autowrite' and 'winfixbuf' options:

tag in file	winfixbuf	autowrite		
current file changed ! option option action				
yes	x	x off	x	goto tag
no	no	x off	x	read other file, goto tag
no	yes	yes off	x	abandon current file, read other file, goto tag
no	yes	no off	on	write current file, read other file, goto tag
no	yes	no off	off	fail
yes	x	yes x	x	goto tag
no	no	no on	x	fail
no	yes	no on	x	fail
no	yes	no on	on	fail
no	yes	no on	off	fail

- If the tag is in the current file, the command will always work.

- If the tag is in another file and the current file was not changed, the

  other file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and a ! is

  added to the command, the changes to the current file are lost, the other
  file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and the

  'autowrite' option is on, the current file will be written, the other
  file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and the

  'autowrite' option is off, the command will fail. If you want to save
  the changes, use the ":w" command and then use ":tag" without an argument.
  This works because the tag is put on the stack anyway. If you want to lose
  the changes you can use the ":tag!" command.
- If the tag is in another file and the window includes 'winfixbuf', the

  command will fail. If the tag is in the same file then it may succeed.

tag-security

Note that Vim forbids some commands, for security reasons. This works like
using the 'secure' option for exrc/vimrc files in the current directory. See
trojan-horse and sandbox.
When the {tagaddress} changes a buffer, you will get a warning message:
        "WARNING: tag command changed a buffer!!!"
In a future version changing the buffer will be impossible. All this for
security reasons: Somebody might hide a nasty command in the tags file, which
would otherwise go unnoticed. Example:

```
:$d|/tag-function-name/
```

In Vi the ":tag" command sets the last search pattern when the tag is searched
for. In Vim this is not done, the previous search pattern is still
remembered, unless the 't' flag is present in 'cpoptions'.

tags-option

The 'tags' option is a list of file names. Each of these files is searched
for the tag. This can be used to use a different tags file than the default
file "tags". It can also be used to access a common tags file.

The next file in the list is not used when:
- A matching static tag for the current buffer has been found.

- A matching global tag has been found.

  This also depends on whether case is ignored. Case is ignored when:
- 'tagcase' is "followic" and 'ignorecase' is set

- 'tagcase' is "ignore"

- 'tagcase' is "smart" and the pattern only contains lower case

  characters.
- 'tagcase' is "followscs" and 'smartcase' is set and the pattern only

contains lower case characters.
If case is not ignored, and the tags file only has a match without matching case, the next tags file is searched for a match with matching case. If no tag with matching case is found, the first match without matching case is used. If case is ignored, and a matching global tag with or without matching case is found, this one is used, no further tags files are searched.

When a tag file name starts with "./", the '.' is replaced with the path of the current file. This makes it possible to use a tags file in the directory where the current file is (no matter what the current directory is). The idea of using "./" is that you can define which tag file is searched first: In the current directory ("tags,./tags") or in the directory of the current file ("./tags,tags").

For example:

```
:set tags=./tags,tags,/home/user/commontags
```

In this example the tag will first be searched for in the file "tags" in the directory where the current file is. Next the "tags" file in the current directory. If it is not found there, then the file "/home/user/commontags" will be searched for the tag.

This can be switched off by including the 'd' flag in 'cpoptions', to make it Vi compatible. "./tags" will then be the tags file in the current directory, instead of the tags file in the directory where the current file is.

Instead of the comma a space may be used. Then a backslash is required for the space to be included in the string option:

```
:set tags=tags\ /home/user/commontags
```

To include a space in a file name use three backslashes. To include a comma in a file name use two backslashes. For example, use:

```
:set tags=tag\\\ file,/home/user/common\\,tags
```

for the files "tag file" and "/home/user/common,tags". The 'tags' option will have the value "tag\ file,/home/user/common\,tags".

If the 'tagrelative' option is on (which is the default) and using a tag file in another directory, file names in that tag file are relative to the directory where the tag file is.

5. Tags file format

tags-file-format E431

ctags

A tags file can be created with an external command, for example "ctags". It will contain a tag for each function. Some versions of "ctags" will also make a tag for each "#defined" macro, typedefs, enums, etc.

Some programs that generate tags files:

ctags	As found on most Unix systems. Only supports C. Only does the basic work.
universal ctags	A maintained version of ctags based on exuberant ctags. See https://ctags.io.

Exuberant_ctags

exuberant ctags	Works for C, C++, Java, Fortran, Eiffel and others. See https://ctags.sourceforge.net. No new version since 2009.
:helptags	For Vim's help files
ptags.py	For Python, in Python. Found in your Python source directory at Tools/scripts/ptags.py.
ptags	For Perl, in Perl. It can be found at https://metacpan.org/pod/Vim::Tag

The lines in the tags file must have one of these two formats:

1. {tagname} {TAB} {tagfile} {TAB} {tagaddress}

2. {tagname} {TAB} {tagfile} {TAB} {tagaddress} {term} {field} ..

Previously an old format was supported, see tag-old-static.

The first format is a normal tag, which is completely compatible with Vi. It is the only format produced by traditional ctags implementations. This is often used for functions that are global, also referenced in other files.

The lines in the tags file can end in <NL> or <CR><NL>. On the Macintosh <CR> also works. The <CR> and <NL> characters can never appear inside a line.

The second format is new. It includes additional information in optional fields at the end of each line. It is backwards compatible with Vi. It is only supported by new versions of ctags (such as Universal ctags or Exuberant ctags).

{tagname}	The identifier. Normally the name of a function, but it can
		be any identifier. It cannot contain a <Tab>.
{TAB}		One <Tab> character. **Note:** previous versions allowed any
		white space here. This has been abandoned to allow spaces in
		{tagfile}.
{tagfile}	The file that contains the definition of {tagname}. It can
		have an absolute or relative path. It may contain environment
		variables and wildcards (although the use of wildcards is
		doubtful). It cannot contain a <Tab>.
{tagaddress}	The Ex command that positions the cursor on the tag. It can
		be any Ex command, although restrictions apply (see
		tag-security). Posix only allows line numbers and search
		commands, which are mostly used.
{term}		;" The two characters semicolon and double quote. This is
		interpreted by Vi as the start of a comment, which makes the
		following be ignored. This is for backwards compatibility
		with Vi, it ignores the following fields. Example:

```
APP     file    /^static int APP;$/;"   v
```

		When {tagaddress} is not a line number or search pattern, then
		{term} must be |;". Here the bar ends the command (excluding
		the bar) and ;" is used to have Vi ignore the rest of the
		line. Example:

```
APP     file.c  call cursor(3, 4)|;"    v
```

{field} ..	A list of optional fields. Each field has the form:

			<Tab>{fieldname}:{value}

		The {fieldname} identifies the field, and can only contain
		alphabetical characters [a-zA-Z].
		The {value} is any string, but cannot contain a <Tab>.
		These characters are special:
			"\t" stands for a <Tab>
			"\r" stands for a <CR>
			"\n" stands for a <NL>
			"\\" stands for a single '\' character

		There is one field that doesn't have a ':'. This is the kind
		of the tag. It is handled like it was preceded with "kind:".
		In the above example, this was "kind:v" (typically variable).
		See the documentation of ctags for the kinds it produces, with
		ctags you can use ctags --list-kinds .

		The only other field currently recognized by Vim is "file:"
		(with an empty value). It is used for a static tag.

The first lines in the tags file can contain lines that start with
	!_TAG_
These are sorted to the first lines, only rare tags that start with "!" can
sort to before them. Vim recognizes two items. The first one is the line
that indicates if the file was sorted. When this line is found, Vim uses
binary searching for the tags file:
!_TAG_FILE_SORTED<Tab>1<Tab>{anything}

A tag file may be case-fold sorted to avoid a linear search when case is
ignored. (Case is ignored when 'ignorecase' is set and 'tagcase' is
"followic", or when 'tagcase' is "ignore".) See 'tagbsearch' for details.
The value '2' should be used then:
!_TAG_FILE_SORTED<Tab>2<Tab>{anything}

The other tag that Vim recognizes is the encoding of the tags file:
!_TAG_FILE_ENCODING<Tab>utf-8<Tab>{anything}
Here "utf-8" is the encoding used for the tags. Vim will then convert the tag
being searched for from 'encoding' to the encoding of the tags file. And when
listing tags the reverse happens. When the conversion fails the unconverted
tag is used.

tag-search

The command can be any Ex command, but often it is a search command.
Examples:
**tag1	file1	/^main(argc, argv)/**
**tag2	file2	108**

The command is always executed with 'magic' not set. The only special
characters in a search pattern are "^" (begin-of-line) and "$" (<EOL>).
See pattern. Note that you must put a backslash before each backslash in
the search text. This is for backwards compatibility with Vi.

E434 E435

If the command is a normal search command (it starts and ends with "/" or
"?"), some special handling is done:
- Searching starts on line 1 of the file.

  The direction of the search is forward for "/", backward for "?".
  Note that 'wrapscan' does not matter, the whole file is always searched.
- If the search fails, another try is done ignoring case. If that fails too,

  a search is done for:

```
"^tagname[ \t]*("
```

(the tag with '^' prepended and "[\t]*(" appended). When using function names, this will find the function name when it is in column 0. This will help when the arguments to the function have changed since the tags file was made. If this search also fails another search is done with:

```
"^[#a-zA-Z_].*\<tagname[ \t]*("
```

This means: A line starting with '#' or an identifier and containing the tag followed by white space and a '('. This will find macro names and function names with a type prepended.

tag-old-static

Until March 2019 (patch 8.1.1092) an outdated format was supported:
{tagfile}:{tagname} {TAB} {tagfile} {TAB} {tagaddress}

This format is for a static tag only. It is obsolete now, replaced by the second format. It is only supported by Elvis 1.x, older Vim versions and a few versions of ctags. A static tag is often used for functions that are local, only referenced in the file {tagfile}. Note that for the static tag, the two occurrences of {tagfile} must be exactly the same. Also see tags-option below, for how static tags are used.

The support was removed, since when you can update to the new Vim version you should also be able to update ctags to one that supports the second format.

6. Include file searches include-search definition-search

E387 E388 E389

These commands look for a string in the current file and in all encountered included files (recursively). This can be used to find the definition of a variable, function or macro. If you only want to search in the current buffer, use the commands listed at pattern-searches.

When a line is encountered that includes another file, that file is searched before continuing in the current buffer. Files included by included files are also searched. When an include file could not be found it is silently ignored. Use the :checkpath command to discover which files could not be found, possibly your 'path' option is not set up correctly. **Note:** the included file is searched, not a buffer that may be editing that file. Only for the current file the lines in the buffer are used.

The string can be any keyword or a defined macro. For the keyword any match will be found. For defined macros only lines that match with the 'define' option will be found. The default is "^#\s*define", which is for C programs. For other languages you probably want to change this. See 'define' for an example for C++. The string cannot contain an end-of-line, only matches within a line are found.

When a match is found for a defined macro, the displaying of lines continues with the next line when a line ends in a backslash.

The commands that start with "[" start searching from the start of the current file. The commands that start with "]" start at the current cursor position.

The 'include' option is used to define a line that includes another file. The default is "\^#\s*include", which is for C programs. **Note:** Vim does not recognize C syntax, if the 'include' option matches a line inside "#ifdef/#endif" or inside a comment, it is searched anyway. The 'isfname' option is used to recognize the file name that comes after the matched pattern.

The 'path' option is used to find the directory for the include files that do not have an absolute path.

The 'comments' option is used for the commands that display a single line or jump to a line. It defines patterns that may start a comment. Those lines are ignored for the search, unless [!] is used. One exception: When the line matches the pattern "^# *define" it is not considered to be a comment.

If you want to list matches, and then select one to jump to, you could use a mapping to do that for you. Here is an example:

```
:map <F4> [I:let nr = input("Which one: ")<Bar>exe "normal " .. nr .. "[\t"<CR>
```

[i

[i Display the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment are ignored (see 'comments' option). If a count is given, the count'th matching line is displayed, and comment lines are not ignored.

]i

]i like "[i", but start at the current cursor position.

:is :isearch

:[range]is[earch][!] [count] [/]pattern[/]
Like "[i" and "]i", but search in [range] lines

(default: whole file).
See :search-args for [/] and [!].

[I

[I Display all lines that contain the keyword under the cursor. Filenames and line numbers are displayed for the found lines. The search starts at the beginning of the file.

]I

]I like "[I", but start at the current cursor position.

:il :ilist

:[range]il[ist][!] [/]pattern[/]
Like "[I" and "]I", but search in [range] lines (default: whole file).
See :search-args for [/] and [!].

[_CTRL-I

[CTRL-I Jump to the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment are ignored (see 'comments' option). If a count is given, the count'th matching line is jumped to, and comment lines are not ignored.

]_CTRL-I

] CTRL-I like "[CTRL-I", but start at the current cursor position.

:ij :ijump

:[range]ij[ump][!] [count] [/]pattern[/]
Like "[CTRL-I" and "] CTRL-I", but search in [range] lines (default: whole file).
See :search-args for [/] and [!].

CTRL-W CTRL-I CTRL-W_CTRL-I CTRL-W_i
CTRL-W i Open a new window, with the cursor on the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment line are ignored (see 'comments' option). If a count is given, the count'th matching line is jumped to, and comment lines are not ignored.

:isp :isplit

:[range]isp[lit][!] [count] [/]pattern[/]
Like "CTRL-W i" and "CTRL-W i", but search in [range] lines (default: whole file).
See :search-args for [/] and [!].

[d

[d Display the first macro definition that contains the macro under the cursor. The search starts from the beginning of the file. If a count is given, the count'th matching line is displayed.

[d-default

Jumps to the previous diagnostic in the current buffer by default. vim.diagnostic.jump() default-mappings

]d

]d like "[d", but start at the current cursor position.

]d-default

Jumps to the next diagnostic in the current buffer by default. vim.diagnostic.jump() default-mappings

:ds :dsearch

:[range]ds[earch][!] [count] [/]string[/]
Like "[d" and "]d", but search in [range] lines (default: whole file).
See :search-args for [/] and [!].

[D

[D Display all macro definitions that contain the macro under the cursor. Filenames and line numbers are displayed for the found lines. The search starts from the beginning of the file.

[D-default

Jumps to the first diagnostic in the current buffer by default. vim.diagnostic.jump() default-mappings

]D

]D like "[D", but start at the current cursor position.

]D-default

Jumps to the last diagnostic in the current buffer by
default. vim.diagnostic.jump() default-mappings

:dli :dlist

:[range]dli[st][!] [/]string[/]
Like [D and]D, but search in [range] lines
(default: whole file).
See :search-args for [/] and [!].
Note: :dl works like :delete with the "l" flag,
not :dlist.

[_CTRL-D

[CTRL-D Jump to the first macro definition that contains the
keyword under the cursor. The search starts from
the beginning of the file. If a count is given, the
count'th matching line is jumped to.

]_CTRL-D

] CTRL-D like "[CTRL-D", but start at the current cursor
position.

:dj :djump

:[range]dj[ump][!] [count] [/]string[/]
Like "[CTRL-D" and "] CTRL-D", but search in
[range] lines (default: whole file).
See :search-args for [/] and [!].

CTRL-W CTRL-D CTRL-W_CTRL-D CTRL-W_d
CTRL-W d Open a new window, with the cursor on the first
macro definition line that contains the keyword
under the cursor. The search starts from the
beginning of the file. If a count is given, the
count'th matching line is jumped to.

CTRL-W_d-default

Mapped to vim.diagnostic.open_float() by default.
default-mappings

:dsp :dsplit

:[range]dsp[lit][!] [count] [/]string[/]
Like "CTRL-W d", but search in [range] lines
(default: whole file).
See :search-args for [/] and [!].

:checkp :checkpath

:checkp[ath] List all the included files that could not be found.

:checkp[ath]! List all the included files.

:search-args

Common arguments for the commands above:
[!] When included, find matches in lines that are recognized as comments.
When excluded, a match is ignored when the line is recognized as a
comment (according to 'comments'), or the match is in a C comment
(after "//" or inside /* */). Note that a match may be missed if a
line is recognized as a comment, but the comment ends halfway the
line. And if the line is a comment, but it is not recognized
(according to 'comments') a match may be found in it anyway. Example:

```
/* comment
   foobar */
```

A match for "foobar" is found, because this line is not recognized as
a comment (even though syntax highlighting does recognize it).
Note: Since a macro definition mostly doesn't look like a comment, the
[!] makes no difference for ":dlist", ":dsearch" and ":djump".
[/] A pattern can be surrounded by "/". Without "/" only whole words are
matched, using the pattern "\<pattern\>". Only after the second "/" a
next command can be appended with "|". Example:

```
:isearch /string/ | echo "the last one"
```

For a ":djump", ":dsplit", ":dlist" and ":dsearch" command the pattern
is used as a literal string, not as a search pattern.

7. Using 'tagfunc' tag-function

It is possible to provide Vim with a function which will generate a list of
tags used for commands like :tag, :tselect, Normal mode tag commands like
CTRL-] and for the taglist() function.

The function used for generating the taglist is specified by setting the
'tagfunc' option. The function will be called with three arguments:
pattern The tag identifier or pattern used during the tag search.
flags String containing flags to control the function behavior.
info Dict containing the following entries:
buf_ffname Full filename which can be used for priority.
user_data Custom data String, if stored in the tag
stack previously by tagfunc.

Note that "a:" needs to be prepended to the argument name when using it.

Currently up to three flags may be passed to the tag function:

'c'	The function was invoked by a normal command being processed (mnemonic: the tag function may use the context around the cursor to perform a better job of generating the tag list.)
'i'	In Insert mode, the user was completing a tag (with i_CTRL-X_CTRL-] or 'complete' contains "`t`" or "`]`").
'r'	The first argument to tagfunc should be interpreted as a pattern (see tag-regexp), such as when using:

```
:tag /pat
```

It is also given when completing in insert mode.
If this flag is not present, the argument is usually taken literally as the full tag name.

Note that when 'tagfunc' is set, the priority of the tags described in tag-priority does not apply. Instead, the priority is exactly as the ordering of the elements in the list returned by the function.

E987

The function should return a List of Dict entries. Each Dict must at least include the following entries and each value must be a string:

name	Name of the tag.
filename	Name of the file where the tag is defined. It is either relative to the current directory or a full path.
cmd	Ex command used to locate the tag in the file. This can be a line number, a search pattern or any other Ex command, like in a tags file (see tags-file-format). A search pattern must start and end with "/" or "?". An invalid value results in E987.

Note that the format is similar to that of taglist(), which makes it possible to use its output to generate the result.
The following fields are optional:

kind	Type of the tag.
user_data	String of custom data stored in the tag stack which can be used to disambiguate tags between operations.

If the function returns v:null instead of a List, a standard tag lookup will be performed instead.

It is not allowed to change the tagstack from inside 'tagfunc'. E986
It is not allowed to close a window or change window from inside 'tagfunc'.
E1299

The following is a hypothetical example of a function used for 'tagfunc'. It uses the output of taglist() to generate the result: a list of tags in the inverse order of file names.

```
vim.bo.tagfunc = function(pattern, flags, info)
  local result = vim.fn.taglist(pattern)
  table.sort(result, function(item1, item2)
    return item1.filename > item2.filename
  end)
  return result
end
```

Note: When executing taglist() the 'tagfunc' function won't be called recursively.

Terminal emulator terminal-emulator

Nvim embeds a VT220/xterm terminal emulator based on libvterm. The terminal is presented as a special 'buftype', asynchronously updated as data is received from the connected program.

Terminal buffers behave like normal buffers, except:
- With 'modifiable', lines can be edited but not deleted.
- 'scrollback' controls how many lines are kept.
- Output is followed ("tailed") if cursor is on the last line.
- 'modified' is the default. You can set 'nomodified' to avoid a warning when closing the terminal buffer.
- 'bufhidden' defaults to "hide".

Start terminal-start

There are several ways to create a terminal buffer:

- Run the :terminal command.
- Call nvim_open_term() or `jobstart(…, {'term': v:true})`.
- Edit a "term://" buffer. Examples:

```
:edit term://bash
:vsplit term://top
```

Note: To open a "term://" buffer from an autocmd, the autocmd-nested modifier is required.

```
autocmd VimEnter * ++nested split term://sh
```

(This is only mentioned for reference; use :terminal instead.)

When the terminal starts, the buffer contents are updated and the buffer is named in the form of `term://{cwd}//{pid}:{cmd}`. This naming scheme is used by :mksession to restore a terminal buffer (by restarting the `{cmd}`).

The terminal environment is initialized as in jobstart-env.

MS-Windows ConPTY terminal-ms-windows terminal-conpty

The system ConPTY (in "kernel32.dll") mangles some VT sequences, which can garble :terminal output. To use a newer ConPTY from the Windows Terminal project, put its "conpty.dll" (and "OpenConsole.exe") next to the Nvim executable. Nvim uses that "conpty.dll" if present, else falls back to the system ConPTY, and logs which one ($NVIM_LOG_FILE):

```
Loaded new ConPTY from conpty.dll
Loaded system ConPTY from kernel32.dll
```

Input terminal-input

To send input, enter Terminal-mode with i, I, a, A or :startinsert. In this mode all keys except <C-\> are sent to the underlying program. If <C-\> is pressed, the next key is sent unless it is <C-N> or <C-O>. Use <C-\><C-N> to return to normal mode. CTRL-_CTRL-N Use <C-\><C-O> to execute one normal mode command and then return to terminal mode. t_CTRL-_CTRL-O

Terminal-mode forces these local options:

- 'cursorlineopt' = number
- 'nocursorcolumn'
- 'scrolloff' = 0
- 'sidescrolloff' = 0

Terminal-mode has its own :tnoremap namespace for mappings, this can be used to automate any terminal interaction.

To map <Esc> to exit terminal-mode:

```
:tnoremap <Esc> <C-\><C-n>
```

To simulate i_CTRL-R in terminal-mode:

```
:tnoremap <expr> <C-R> '<C-\><C-N>"'.nr2char(getchar()).'pi'
```

To use ALT+{h,j,k,l} to navigate windows from any mode:

```
:tnoremap <A-h> <C-\><C-N><C-w>h
:tnoremap <A-j> <C-\><C-N><C-w>j
:tnoremap <A-k> <C-\><C-N><C-w>k
:tnoremap <A-l> <C-\><C-N><C-w>l
:inoremap <A-h> <C-\><C-N><C-w>h
:inoremap <A-j> <C-\><C-N><C-w>j
:inoremap <A-k> <C-\><C-N><C-w>k
:inoremap <A-l> <C-\><C-N><C-w>l
:nnoremap <A-h> <C-w>h
:nnoremap <A-j> <C-w>j
:nnoremap <A-k> <C-w>k
:nnoremap <A-l> <C-w>l
```

You can also create menus similar to terminal mode mappings, but you have to use :tlmenu instead of :tmenu.

Mouse input has the following behavior:

- If the program has enabled mouse events, the corresponding events will be forwarded to the program.

- If mouse events are disabled (the default), terminal focus will be lost and the event will be processed as in a normal buffer.
- If another window is clicked, terminal focus will be lost and nvim will jump to the clicked window
- If the mouse wheel is used while the mouse is positioned in another window, the terminal won't lose focus and the hovered window will be scrolled.

Configuration terminal-config

- Options: 'modified', 'scrollback'
- Events: TermOpen, TermEnter, TermLeave, TermClose
- Event groups: "nvim.terminal" default-autocmds
- Highlight groups: hl-TermCursor

Terminal sets local defaults for some options, which may differ from your global configuration.

- 'list' is disabled
- 'wrap' is disabled
- 'number' is disabled
- 'relativenumber' is disabled
- 'signcolumn' is set to "no"
- 'foldcolumn' is set to "0"

You can change the defaults with a TermOpen autocommand:

```
:autocmd TermOpen * setlocal list
```

By default, "[Process exited]" is displayed when the terminal process ends. To disable that, you can delete the "nvim.terminal" TermClose handler (this also deletes other default-autocmds TermClose functionality):

```
:autocmd! nvim.terminal TermClose
```

TERMINAL COLORS

The `{g,b}:terminal_color_x` variables control the terminal color palette, where x is the color index between 0 and 15 inclusive. The variables are read during TermOpen. The value must be a color name or hexadecimal string. Example:

```
let g:terminal_color_4 = '#ff0000'
let g:terminal_color_5 = 'green'
```

Only works for RGB UIs (see 'termguicolors'); for 256-color terminals the color index is just forwarded.

Editor highlighting (syntax-highlighting, highlight-groups, etc.) has higher precedence: it is applied after terminal colors are resolved.

EVENTS terminal-events

Applications running in a :terminal buffer can send requests, which Nvim exposes via the TermRequest event.

OSC 7: change working directory terminal-osc7

Shells can emit the "OSC 7" sequence to announce when the current directory (CWD) changed.

You can configure your shell init (e.g. ~/.bashrc) to emit OSC 7, or your terminal may attempt to do it for you.

To configure bash to emit OSC 7:

```
function print_osc7() {
  printf '\033]7;file://%s\033\\' "$PWD"
}
PROMPT_COMMAND='print_osc7'
```

Having ensured that your shell emits OSC 7, you can now handle it in Nvim. The following code runs :bcd whenever your shell CWD changes, so the :terminal buffer-local directory always follows the shell:

```
vim.api.nvim_create_autocmd('TermRequest', {
  desc = 'Handles OSC 7 dir change requests',
  callback = function(ev)
    local val, n = string.gsub(ev.data.sequence, '\027]7;file://[^/]*', '')
    if n > 0 then
      -- OSC 7: dir-change
      local dir = val
      if vim.fn.isdirectory(dir) == 0 then
        vim.notify('invalid dir: '..dir)
        return
      end
      vim.cmd.bcd(dir)
    end
  end
})
```

To try it out, select the above code and source it with `:'<,'>lua`, then run this command in a :terminal buffer:

```
printf "\033]7;file://./foo/bar\033\\"
```

OSC 52: write to system clipboard terminal-osc52

Applications in the :terminal buffer can write to the system clipboard by emitting an OSC 52 sequence. Example:

```
printf '\033]52;;%s\033\\' "$(echo -n 'Hello world' | base64)"
```

Nvim uses the configured clipboard provider to write to the system clipboard. Reading from the system clipboard with OSC 52 is not supported, as this would allow any arbitrary program in the :terminal to read the user's clipboard.

OSC 52 sequences sent from the :terminal buffer do not emit a TermRequest event. The event is handled directly by Nvim and is not forwarded to plugins.

OSC 133: shell integration terminal-osc133 shell-prompt

Shells can emit semantic escape sequences (OSC 133) to mark where each prompt starts and ends. The start of a prompt is marked by sequence `OSC 133 ; A ST`, and the end by `OSC 133 ; B ST`.

You can configure your shell init (e.g. ~/.bashrc) to emit OSC 133 sequences, or your terminal may attempt to do it for you (assuming your shell config doesn't interfere).

- fish: https://fishshell.com/docs/current/relnotes.html#improved-terminal-support
- kitty: https://sw.kovidgoyal.net/kitty/shell-integration/
- powershell: https://learn.microsoft.com/en-us/windows/terminal/tutorials/shell-integration#powershell-pwshexe
- vscode: https://code.visualstudio.com/docs/terminal/shell-integration

To configure bash to mark the start of each prompt, set $PROMPT_COMMAND:

```
# Prompt start:
PROMPT_COMMAND='printf "\033]133;A\007"'
```

terminal_]] terminal_[[The]] and [[motions jump to the next/previous prompts, if your shell emits OSC 133 as described above.

shell-prompt-signs

To annotate each terminal prompt with a sign, call nvim_buf_set_extmark() from a TermRequest handler:

```
vim.api.nvim_create_autocmd('TermOpen', {
  command = 'setlocal signcolumn=auto',
})
local ns = vim.api.nvim_create_namespace('my.terminal.prompt')
vim.api.nvim_create_autocmd('TermRequest', {
  callback = function(ev)
    if string.match(ev.data.sequence, '^\027]133;A') then
      local lnum = ev.data.cursor[1]
      vim.api.nvim_buf_set_extmark(ev.buf, ns, lnum - 1, 0, {
        sign_text = '▶',
        sign_hl_group = 'SpecialChar',
      })
    end
  end,
})
```

Status Variables terminal-status

Terminal buffers maintain some buffer-local variables and options. The values are initialized before TermOpen, so you can use them in a local 'statusline'. Example:

```
:autocmd TermOpen * setlocal statusline=%{b:term_title}
```

- b:term_title Terminal title (user-writable), typically displayed in the window title or tab title of a graphical terminal emulator. Terminal programs can set this by emitting an escape sequence.
- 'channel' Terminal PTY job-id. Can be used with chansend() to send input to the terminal.
- The TermClose event gives the terminal job exit code in the v:event "status" field. For example, this autocommand outputs the terminal's exit code to :messages:

  ```
  autocmd TermClose * echom 'Terminal exited with status '..v:event.status
  ```

  Use jobwait() to check if the terminal job has finished:

  ```
  let running = jobwait([&channel], 0)[0] == -1
  ```

Concepts terminal-concepts

TODO

:Termdebug plugin terminal-debug terminal-debugger

package-termdebug termdebug

The Terminal debugging plugin can be used to debug a program with gdb and view the source code in a Vim window. Since this is completely contained inside Vim this also works remotely over an ssh connection.

Starting

termdebug-starting

Load the plugin with this command:

```
packadd termdebug
```

When loading the plugin from the vimrc file, add the "!" attribute:

```
packadd! termdebug
```

:Termdebug

To start debugging use `:Termdebug` or `:TermdebugCommand` followed by the command name, for example:

```
:Termdebug vim
```

This opens two windows:

- gdb window: A terminal window in which "gdb vim" is executed. Here you can directly interact with gdb.
- program window: A terminal window for the executed program. When "run" is used in gdb the program I/O will happen in this window, so that it does not interfere with controlling gdb.

The current window is used to show the source code. When gdb pauses the source file location will be displayed, if possible. A sign is used to highlight the current position, using highlight group debugPC.

If the buffer in the current window is modified, another window will be opened to display the current gdb position.

Focus the terminal of the executed program to interact with it. This works the same as any command running in a terminal window.

When the debugger ends, typically by typing "quit" in the gdb window, the two opened windows are closed.

Only one debugger can be active at a time. :TermdebugCommand
If you want to give specific commands to the command being debugged, you can use the `:TermdebugCommand` command followed by the command name and additional parameters.

```
:TermdebugCommand vim --clean -c ':set nu'
```

Both the `:Termdebug` and `:TermdebugCommand` support an optional "!" bang argument to start the command right away, without pausing at the gdb window (and cursor will be in the debugged window). For example:

```
:TermdebugCommand! vim --clean
```

To attach gdb to an already running executable or use a core file, pass extra arguments. E.g.:

```
:Termdebug vim core
:Termdebug vim 98343
```

If no argument is given, you'll end up in a gdb window, in which you need to specify which command to run using e.g. the gdb `file` command.

Example session

termdebug-example

Start in the Vim "src" directory and build Vim:

```
% make
```

Start Vim:

```
% ./vim
```

Load the termdebug plugin and start debugging Vim:

```
:packadd termdebug
:Termdebug vim
```

You should now have three windows:
- source: where you started
- gdb: you can type gdb commands here
- program: the executed program will use this window

Put focus on the gdb window and type:

```
break ex_help
run
```

Vim will start running in the program window. Put focus there and type:

```
:help gui
```

Gdb will run into the ex_help breakpoint. The source window now shows the ex_cmds.c file. A red "1 " marker will appear in the signcolumn where the breakpoint was set. The line where the debugger stopped is highlighted. You can now step through the program. You will see the highlighting move as the debugger executes a line of source code.

Run :Over a few times until the for loop is highlighted. Put the cursor on the end of "eap->arg", then call ":Eval". You will see this displayed:

```
"eap->arg": 0x555555e68855 "gui"
```

This way you can inspect the value of local variables. You can also focus the gdb window and use a "print" command, e.g.:

```
print *eap
```

If mouse pointer movements are working, Vim will also show a balloon when the mouse rests on text that can be evaluated by gdb. You can also use the "K" mapping that will either use Nvim floating windows to show the results.

Now go back to the source window and put the cursor on the first line after the for loop, then type:

```
:Break
```

You will see a "1" marker appear, this indicates the new breakpoint. Now run ":Cont" command and the code until the breakpoint will be executed.

You can type more advanced commands in the gdb window. For example, type:

```
watch curbuf
```

Now run ":Cont" (or type "cont" in the gdb window). Execution will now continue until the value of "curbuf" changes, which is in do_ecmd(). To remove this watchpoint again type in the gdb window:

```
delete 3
```

You can see the stack by typing in the gdb window:

```
where
```

Move through the stack frames, e.g. with:

```
frame 3
```

The source window will show the code, at the point where the call was made to a deeper level.

Stepping through code

termdebug-stepping

Put focus on the gdb window to type commands there. Some common ones are:
- CTRL-C: interrupt the program
- next: execute the current line and stop at the next line
- step: execute the current line and stop at the next statement, entering functions
- until: execute until past the current cursor line or past a specified position or the current stack frame returns
- finish: execute until leaving the current function
- where: show the stack
- frame N: go to the Nth stack frame
- continue: continue execution

:Run :Arguments In the window showing the source code these commands can be used to control gdb:
- `:Run` [args] run the program with [args] or the previous arguments
- `:Arguments {args}` set arguments for the next `:Run`
- :Break set a breakpoint at the cursor position
- :Break `[{position}]` [thread `{nr}`] [if `{expr}`] set a breakpoint at the specified position if `{position}` is omitted, use the current file and line thread `{nr}` limits the breakpoint to one thread if `{expr}` sets a conditional breakpoint. Examples:

  ```
  :Break if argc == 1
  :Break 42 thread 3 if x > 10
  :Break main
  ```

- :Tbreak set a temporary breakpoint at the cursor position
- :Tbreak `[{position}]` [thread `{nr}`] [if `{expr}`] like `:Break`, but the breakpoint is deleted after it is hit once. Examples:

  ```
  :Tbreak if argc == 1
  :Tbreak 42 thread 3 if x > 10
  :Tbreak main
  ```

- :Clear delete the breakpoint at the cursor position
- :ToggleBreak set a breakpoint at the cursor position or delete all breakpoints at the cursor positoin
- :Step execute the gdb "step" command
- :Over execute the gdb "next" command (`:Next` is a Vim command)
- :Until execute the gdb "until" command
- :Finish execute the gdb "finish" command
- :Continue execute the gdb "continue" command
- :RunOrContinue execute the gdb "continue" command if program is running, otherwise run the program
- :Stop interrupt the program

If gdb stops at a source line and there is no window currently showing the source code, a new window will be created for the source code. This also happens if the buffer in the source code window has been modified and can't be abandoned.

Gdb gives each breakpoint a number. In Vim the number shows up in the sign column, with a red background. You can use these gdb commands:
- info break list breakpoints
- delete N delete breakpoint N You can also use the `:Clear` command if the cursor is in the line with the breakpoint, or use the "Clear breakpoint" right-click menu entry.

Inspecting variables

termdebug-variables :Evaluate
- `:Evaluate` evaluate the expression under the cursor
- K same (see termdebug_map_K to disable)
- `:Evaluate {expr}` evaluate `{expr}`
- `:'<,'>Evaluate` evaluate the Visually selected text

This is similar to using "print" in the gdb window. You can usually shorten `:Evaluate` to `:Ev`. The result is displayed in a floating window. You can move the cursor to this window by running `:Evaluate` (or K) again.

Navigating stack frames

termdebug-frames :Frame :Up :Down
- `:Frame` [frame] select frame [frame], which is a frame number, address, or function name (default: current frame)

- :Up [count] go up [count] frames (default: 1; the frame that called the current)
- + same (see termdebug_map_plus to disable)
- :Down [count] go down [count] frames (default: 1; the frame called by the current)
- - same (see termdebug_map_minus to disable)

Other commands

termdebug-commands

- :Gdb jump to the gdb window
- :Program jump to the window with the running program
- :Source jump to the window with the source code, create it if there isn't one
- :Asm jump to the window with the disassembly, create it if there isn't one
- :Var jump to the window with the local and argument variables, create it if there isn't one. This window updates whenever the program is stopped

Events

termdebug-events

Four autocommands can be used:

```
au User TermdebugStartPre  echomsg 'debugging starting'
au User TermdebugStartPost echomsg 'debugging started'
au User TermdebugStopPre   echomsg 'debugging stopping'
au User TermdebugStopPost  echomsg 'debugging stopped'
```

- TermdebugStartPre Before starting debugging. Not triggered if the debugger is already running or the debugger command cannot be executed.
- TermdebugStartPost After debugging has initialized. If a "!" bang is passed to :Termdebug or :TermdebugCommand the event is triggered before running the provided command in gdb.
- TermdebugStopPre Before debugging ends, when gdb is terminated, most likely after issuing a "quit" command in the gdb window.
- TermdebugStopPost After debugging has ended, gdb-related windows are closed, debug buffers wiped out and the state before the debugging was restored.

Customizing

termdebug-customizing g:termdebug_config In the past several global variables were used for configuration. These are deprecated and using the g:termdebug_config dictionary is preferred. When g:termdebug_config exists the other global variables will NOT be used. The recommended way is to start with an empty dictionary:

```
let g:termdebug_config = {}
```

Then you can add entries to the dictionary as mentioned below. The deprecated global variable names are mentioned for completeness. If you are switching over to using g:termdebug_config you can find the old variable name and take over the value, then delete the deprecated variable.

Prompt mode

termdebug-prompt

When on MS-Windows, gdb will run in a buffer with 'buftype' set to "prompt". This works slightly differently:

- The gdb window will be in Insert mode while typing commands. Go to Normal mode with <Esc>, then you can move around in the buffer, copy/paste, etc. Go back to editing the gdb command with any command that starts Insert mode, such as a or i.
- A separate :terminal window will be opened to run the debugged program in.

termdebug_use_prompt

Prompt mode can be used with:

```
let g:termdebug_config['use_prompt'] = 1
```

If there is no g:termdebug_config you can use:

```
let g:termdebug_use_prompt = 1
```

Mappings

The termdebug plugin enables a few default mappings. All those mappings are reset to their original values once the termdebug session concludes.

termdebug_map_K termdebug-mappings The K key is normally mapped to :Evaluate unless a buffer local (:map-local) mapping to K already exists. If you do not want this use:

```
let g:termdebug_config['map_K'] = 0
```

If there is no g:termdebug_config you can use:

```
let g:termdebug_map_K = 0
```

termdebug_map_minus

The - key is normally mapped to :Down unless a buffer local mapping to the - key already exists. If you do not want this use:

```
let g:termdebug_config['map_minus'] = 0
```

termdebug_map_plus

The + key is normally mapped to :Up unless a buffer local mapping to the + key already exists. If you do not want this use:

```
let g:termdebug_config['map_plus'] = 0
```

termdebug_disasm_window

If you want the Asm window shown by default, set the "disasm_window" flag to
1. The "disasm_window_height" entry can be used to set the window height:

```
let g:termdebug_config['disasm_window'] = 1
let g:termdebug_config['disasm_window_height'] = 15
```

If there is no g:termdebug_config you can use:

```
let g:termdebug_disasm_window = 15
```

Any value greater than 1 will set the Asm window height to that value. If the current window has enough horizontal space, it will be vertically split and the Asm window will be shown side by side with the source code window (and the height option won't be used).

termdebug_variables_window

If you want the Var window shown by default, set the "variables_window" flag to 1. The "variables_window_height" entry can be used to set the window height:

```
let g:termdebug_config['variables_window'] = 1
let g:termdebug_config['variables_window_height'] = 15
```

If there is no g:termdebug_config you can use:

```
let g:termdebug_variables_window = 15
```

Any value greater than 1 will set the Var window height to that value. If the current window has enough horizontal space, it will be vertically split and the Var window will be shown side by side with the source code window (and the height options won't be used).

Communication

termdebug-communication

There is another, hidden, buffer, which is used for Vim to communicate with gdb. The buffer name is "gdb communication". Do not delete this buffer, it will break the debugger.

Gdb has some weird behavior, the plugin does its best to work around that. For example, after typing "continue" in the gdb window a `CTRL-C` can be used to interrupt the running program. But after using the MI command "-exec-continue" pressing `CTRL-C` does not interrupt. Therefore you will see "continue" being used for the `:Continue` command, instead of using the communication channel.

GDB command

g:termdebugger

To change the name of the gdb command, set "debugger" entry in g:termdebug_config or the "g:termdebugger" variable before invoking `:Termdebug`:

```
let g:termdebug_config['command'] = "mygdb"
```

If there is no g:termdebug_config you can use:

```
let g:termdebugger = "mygdb"
```

If the command needs an argument use a List:

```
let g:termdebug_config['command'] = ['rr', 'replay', '--']
```

If there is no g:termdebug_config you can use:

```
let g:termdebugger = ['rr', 'replay', '--']
```

If you are a mouse person, you can also define a mapping using your right click to one of the terminal command like evaluate the variable under the cursor:

```
nnoremap <RightMouse> :Evaluate<CR>
```

or set/unset a breakpoint:

```
nnoremap <RightMouse> :Break<CR>
```

Several arguments will be added to make gdb work well for the debugger. If you want to modify them, add a function to filter the argument list:

```
let g:termdebug_config['command_filter'] = MyDebugFilter
```

If you do not want the arguments to be added, but you do need to set the "pty", use a function to add the necessary arguments:

```
let g:termdebug_config['command_add_args'] = MyAddArguments
```

The function will be called with the list of arguments so far, and a second argument that is the name of the pty.

gdb-version

Only debuggers fully compatible with gdb will work. Vim uses the GDB/MI interface. The "new-ui" command requires gdb version 7.12 or later. If you get this error:

```
Undefined command: "new-ui". Try "help".
```

Then your gdb is too old.

Colors

hl-debugPC hl-debugBreakpoint The color of the signs can be adjusted with these highlight groups:

- debugPC the current position
- debugBreakpoint a breakpoint

The defaults are, when 'background' is "light":

```
hi debugPC term=reverse ctermbg=lightblue guibg=lightblue
hi debugBreakpoint term=reverse ctermbg=red guibg=red
```

When 'background' is "dark":

```
hi debugPC term=reverse ctermbg=darkblue guibg=darkblue
hi debugBreakpoint term=reverse ctermbg=red guibg=red
```

Shortcuts

termdebug_shortcuts

You can define your own shortcuts (mappings) to control gdb, that can work in any window, using the TermDebugSendCommand() function. Example:

```
map ,w :call TermDebugSendCommand('where')<CR>
```

The argument is the gdb command.

Popup menu

termdebug_popup

By default the Termdebug plugin sets 'mousemodel' to "popup_setpos" and adds these entries to the popup menu:

- Set breakpoint `:Break`
- Clear breakpoint `:Clear`
- Evaluate `:Evaluate` If you don't want this then disable it with:

```
let g:termdebug_config['popup'] = 0
```

If there is no g:termdebug_config you can use:

```
let g:termdebug_popup = 0
```

Change default signs

termdebug_signs

Termdebug uses the hex number of the breakpoint ID in the signcolumn to represent breakpoints. If it is greater than "0xFF", then it will be displayed as "F+", because there are only two screen cells available for the sign. You may also use decimal breakpoint signs instead, in which case IDs greater than 99 will be displayed as "9+".

If you want to customize the breakpoint signs to show >> in the signcolumn:

```
let g:termdebug_config['sign'] = '>>'
```

You can also specify individual signs for the first several breakpoints:

```
let g:termdebug_config['signs'] = ['>1', '>2', '>3', '>4', '>5', '>6', '>7', '>8', '>9']
let g:termdebug_config['sign'] = '>>'
```

If you would like to use decimal (base 10) breakpoint signs:

```
let g:termdebug_config['sign_decimal'] = 1
```

If the variable g:termdebug_config does not yet exist, you can use:

```
let g:termdebug_config = {'sign': '>>'}
```

Likewise, to enable decimal signs:

```
let g:termdebug_config = {'sign_decimal': 1}
```

Vim window width

termdebug_wide

To change the width of the Vim window when debugging starts and use a vertical split:

```
let g:termdebug_config['wide'] = 163
```

If there is no g:termdebug_config you can use:

```
let g:termdebug_wide = 163
```

This will set 'columns' to 163 when `:Termdebug` is used. The value is restored when quitting the debugger.

If the wide value is set and 'columns' is already a greater value, then a vertical split will be used without modifying 'columns'.

Set the wide value to 1 to use a vertical split without ever changing 'columns'. This is useful when the terminal can't be resized by Vim.

Tips and ideas for using Vim

These are just a few that we thought would be helpful for many users.
You can find many more tips on the wiki. The URL can be found on
https://www.vim.org

Don't forget to browse the user manual, it also contains lots of useful tips
usr_toc.txt.

Editing C programs

C-editing

There are quite a few features in Vim to help you edit C program files. Here
is an overview with tags to jump to:

usr_29.txt	Moving through programs chapter in the user manual.
usr_30.txt	Editing programs chapter in the user manual.
C-indenting	Automatically set the indent of a line while typing text.
=	Re-indent a few lines.
format-comments	Format comments.
:checkpath	Show all recursively included files.
[i	Search for identifier under cursor in current and included files.
[_CTRL-I	Jump to match for "[i"
[I	List all lines in current and included files where identifier under the cursor matches.
[d	Search for define under cursor in current and included files.
CTRL-]	Jump to tag under cursor (e.g., definition of a function).
CTRL-T	Jump back to before a CTRL-] command.
:tselect	Select one tag out of a list of matching tags.
gd	Go to Declaration of local variable under cursor.
gD	Go to Declaration of global variable under cursor.
gf	Go to file name under the cursor.
%	Go to matching (), {}, [], /* */, #if, #else, #endif.
[/	Go to previous start of comment.
]/	Go to next end of comment.
[#	Go back to unclosed #if, #ifdef, or #else.
]#	Go forward to unclosed #else or #endif.
[(	Go back to unclosed '('
])	Go forward to unclosed ')'
[{	Go back to unclosed '{'
]}	Go forward to unclosed '}'
v_ab	Select "a block" from "[(" to "])", including braces
v_ib	Select "inner block" from "[(" to "])"
v_aB	Select "a block" from [{ to]}, including brackets
v_iB	Select "inner block" from [{ to]}

Finding where identifiers are used

ident-search

You probably already know that tags can be used to jump to the place where a
function or variable is defined. But sometimes you wish you could jump to all
the places where a function or variable is being used. This is possible in
two ways:

1. Using the :grep command. This should work on most Unix systems,
   but can be slow (it reads all files) and only searches in one directory.
2. Using ID utils. This is fast and works in multiple directories. It uses a
   database to store locations. You will need some additional programs for
   this to work. And you need to keep the database up to date.

Using the GNU id-tools:

What you need:

- The GNU id-tools installed (mkid is needed to create ID and lid is needed to
  use the macros).
- An identifier database file called "ID" in the current directory. You can
  create it with the shell command "mkid file1 file2 ..".

Put this in your init.vim:

```
map _u :call ID_search()<Bar>execute "/\\<" .. g:word .. "\\>"<CR>
map _n :n<Bar>execute "/\\<" .. g:word .. "\\>"<CR>

function! ID_search()
  let g:word = expand("<cword>")
  let x = system("lid --key=none " .. g:word)
  let x = substitute(x, "\n", " ", "g")
  execute "next " .. x
endfun
```

To use it, place the cursor on a word, type "_u" and vim will load the file that contains the word. Search for the next occurrence of the word in the same file with "n". Go to the next file with "_n".

This has been tested with id-utils-3.2 (which is the name of the id-tools archive file on your closest gnu-ftp-mirror).

[the idea for this comes from Andreas Kutschera]

Scrolling in Insert mode

scroll-insert

If you are in insert mode and you want to see something that is just off the screen, you can use CTRL-X CTRL-E and CTRL-X CTRL-Y to scroll the screen.
i_CTRL-X_CTRL-E

To make this easier, you could use these mappings:

```
:inoremap <C-E> <C-X><C-E>
:inoremap <C-Y> <C-X><C-Y>
```

You then lose the ability to copy text from the line above/below the cursor i_CTRL-E.

Also consider setting 'scrolloff' to a larger value, so that you can always see some context around the cursor. If 'scrolloff' is bigger than half the window height, the cursor will always be in the middle and the text is scrolled when the cursor is moved up/down.

Smooth scrolling

scroll-smooth

If you like the scrolling to go a bit smoother, you can use these mappings:

```
:map <C-U> <C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y>
:map <C-D> <C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E>
```

Correcting common typing mistakes

type-mistakes

When there are a few words that you keep on typing in the wrong way, make abbreviations that correct them. For example:

```
:ab teh the
:ab fro for
```

Counting words, lines, etc.

count-items

To count how often any pattern occurs in the current buffer use the substitute command and add the 'n' flag to avoid the substitution. The reported number of substitutions is the number of items. Examples:

```
:%s/./&/gn              characters
:%s/\i\+/&/gn           words
:%s/^//n                lines
:%s/the/&/gn            "the" anywhere
:%s/\<the\>/&/gn        "the" as a word
```

You might want to reset 'hlsearch' or do ":nohlsearch".
Add the 'e' flag if you don't want an error when there are no matches.

An alternative is using v_g_CTRL-G in Visual mode.

If you want to find matches in multiple files use :vimgrep.

count-bytes

If you want to count bytes, you can use this:

```
        Visually select the characters (block is also possible)
        Use "y" to yank the characters
        Use the strlen() function:
```

```
:echo strlen(@")
```

A line break is counted for one byte.

Restoring the cursor position

restore-position

Sometimes you want to write a mapping that makes a change somewhere in the file and restores the cursor position, without scrolling the text. For example, to change the date mark in a file:

```
:map <F2> msHmtgg/Last [cC]hange:\s*/e+1<CR>"_D"=strftime("%Y %b %d")<CR>p'tzt`s
```

Breaking up saving the position:

```
        ms      store cursor position in the 's' mark
```

```
        H       go to the first line in the window
        mt      store this position in the 't' mark
```

Breaking up restoring the position:

```
        't      go to the line previously at the top of the window
        zt      scroll to move this line to the top of the window
        `s      jump to the original position of the cursor
```

For something more advanced see winsaveview() and winrestview().

Renaming files

rename-files

Say I have a directory with the following files in them (directory picked at random :-):

```
buffer.c
charset.c
digraph.c

...
```

and I want to rename *.c *.bla. I'd do it like this:

```
$ vim
:r !ls *.c
:%s/\(.*\).c/mv & \1.bla
:w !sh
:q!
```

Change a name in multiple files

change-name

Example for using a script file to change a name in several files:

Create a file "subs.vim" containing substitute commands and a :update command:

```
:%s/Jones/Smith/g
:%s/Allen/Peter/g
:update
```

Execute Vim on all files you want to change, and source the script for each argument:

```
vim *.let
argdo source subs.vim
```

See :argdo.

Speeding up external commands

speed-up

In some situations, execution of an external command can be very slow. This can also slow down wildcard expansion on Unix. Here are a few suggestions to increase the speed.

If your .cshrc (or other file, depending on the shell used) is very long, you should separate it into a section for interactive use and a section for non-interactive use (often called secondary shells). When you execute a command from Vim like ":!ls", you do not need the interactive things (for example, setting the prompt). Put the stuff that is not needed after these lines:

```
if ($?prompt == 0) then
        exit 0
endif
```

Another way is to include the "-f" flag in the 'shell' option, e.g.:

```
:set shell=csh\ -f
```

(the backslash is needed to include the space in the option).
This will make csh completely skip the use of the .cshrc file. This may cause some things to stop working though.

Useful mappings

useful-mappings

Here are a few mappings that some people like to use.

map-backtick

```
:map ' `
```

Make the single quote work like a backtick. Puts the cursor on the column of a mark, instead of going to the first non-blank character in the line.

emacs-keys

For Emacs-style editing on the command-line:

```
" start of line
:cnoremap <C-A>         <Home>
" back one character
:cnoremap <C-B>         <Left>
" delete character under cursor
:cnoremap <C-D>         <Del>
" end of line
:cnoremap <C-E>         <End>
" forward one character
:cnoremap <C-F>         <Right>
" recall newer command-line
:cnoremap <C-N>         <Down>
" recall previous (older) command-line
:cnoremap <C-P>         <Up>
" back one word
:cnoremap <Esc><C-B>    <S-Left>
" forward one word
:cnoremap <Esc><C-F>    <S-Right>
```

format-bullet-list

This mapping will format any bullet list. It requires that there is an empty
line above and below each list entry. The expression commands are used to
be able to give comments to the parts of the mapping.

```
:let m =     ":map _f  :set ai<CR>"   " need 'autoindent' set
:let m ..= "{O<Esc>"                  " add empty line above item
:let m ..= "}{()^W"                   " move to text after bullet
:let m ..= "i     <CR>     <Esc>"     " add space for indent
:let m ..= "gq}"                      " format text after the bullet
:let m ..= "{dd"                      " remove the empty line
:let m ..= "5lDJ"                     " put text after bullet
:execute m                            |" define the mapping
```

(<> notation <>. Note that this is all typed literally. ^W is "^" "W", not

CTRL-W.)

Note that the last comment starts with |", because the ":execute" command
doesn't accept a comment directly.

You also need to set 'textwidth' to a non-zero value, e.g.,

```
:set tw=70
```

A mapping that does about the same, but takes the indent for the list from the
first line (**Note:** this mapping is a single long line with a lot of spaces):

```
:map _f :set ai<CR>}{a                                                  <Esc>WWmmkD`mi<CR><Esc>kkddpJgq}'mJO<Esc>j
```

collapse

These two mappings reduce a sequence of empty (;b) or blank (;n) lines into a
single line

```
:map ;b   GoZ<Esc>:g/^$/.,/./-j<CR>Gdd
:map ;n   GoZ<Esc>:g/^[ <Tab>]*$/.,/[^ <Tab>]/-j<CR>Gdd
```

Compressing the help files

gzip-helpfile

For those of you who are really short on disk space, you can compress the help
files and still be able to view them with Vim. This makes accessing the help
files a bit slower and requires the "gzip" program.

(1) Compress all the help files: "gzip doc/*.txt".

(2) Edit "doc/tags" and change the ".txt" to ".txt.gz":

```
:%s=\(\t.*\.txt\)\t=\1.gz\t=
```

(3) Add this line to your vimrc:

```
set helpfile={dirname}/help.txt.gz
```

Where {dirname} is the directory where the help files are. The gzip plugin
will take care of decompressing the files.
You must make sure that $VIMRUNTIME is set to where the other Vim files are,
when they are not in the same location as the compressed "doc" directory. See
$VIMRUNTIME.

Hex editing

hex-editing using-xxd

See section 23.3 of the user manual.

If one has a particular extension that one uses for binary files (such as exe, bin, etc), you may find it helpful to automate the process with the following bit of autocmds for your init.vim. Change that "*.bin" to whatever comma-separated list of extension(s) you find yourself wanting to edit:

```
" vim -b : edit binary using xxd-format!
augroup Binary
  autocmd!
  autocmd BufReadPre  *.bin set binary
  autocmd BufReadPost *.bin
    \ if &binary
    \ |   execute "silent %!xxd -c 32"
    \ |   set filetype=xxd
    \ |   redraw
    \ | endif
  autocmd BufWritePre *.bin
    \ if &binary
    \ |   let s:view = winsaveview()
    \ |   execute "silent %!xxd -r -c 32"
    \ | endif
  autocmd BufWritePost *.bin
    \ if &binary
    \ |   execute "silent %!xxd -c 32"
    \ |   set nomodified
    \ |   call winrestview(s:view)
    \ |   redraw
    \ | endif
augroup END
```

Using <> notation in autocommands

autocmd-<>

The <> notation is not recognized in the argument of an :autocmd. To avoid having to use special characters, you could use a self-destroying mapping to get the <> notation and then call the mapping from the autocmd. Example:

map-self-destroy

```
" This is for automatically adding the name of the file to the menu list.
" It uses a self-destroying mapping!
" 1. use a line in the buffer to convert the 'dots' in the file name to \.
" 2. store that in register '"'
" 3. add that name to the Buffers menu list
" WARNING: this does have some side effects, like overwriting the
" current register contents and removing any mapping for the "i" command.
"
autocmd BufNewFile,BufReadPre * nmap i :nunmap i<CR>O<C-R>%<Esc>:.g/\./s/\./\\./g<CR>0"9y$u:menu Buffers.<C-R>9 :buffer <C-R>%<C-V><CR>
<CR>
autocmd BufNewFile,BufReadPre * normal i
```

Another method, perhaps better, is to use the ":execute" command. In the string you can use the <> notation by preceding it with a backslash. Don't forget to double the number of existing backslashes and put a backslash before '"'.

```
autocmd BufNewFile,BufReadPre * exe "normal O\<C-R>%\<Esc>:.g/\\./s/\\./\\\\./g\<CR>0\"9y$u:menu Buffers.\<C-R>9 :buffer \<C-R>%\<C-V>\
<CR>\<CR>"
```

For a real buffer menu, user functions should be used (see :function), but then the <> notation isn't used, which defeats using it as an example here.

Highlighting matching parens

match-parens

This example shows the use of a few advanced tricks:

- using the CursorMoved autocommand event
- using searchpairpos() to find a matching paren
- using synID() to detect whether the cursor is in a string or comment
- using :match to highlight something
- using a pattern to match a specific position in the file.

This should be put in a Vim script file, since it uses script-local variables. It skips matches in strings or comments, unless the cursor started in string or comment. This requires syntax highlighting.

A slightly more advanced version is used in the matchparen plugin.

```
let s:paren_hl_on = 0
function s:Highlight_Matching_Paren()
  if s:paren_hl_on
    match none
    let s:paren_hl_on = 0
  endif

  let c_lnum = line('.')
  let c_col = col('.')

  let c = getline(c_lnum)[c_col - 1]
  let plist = split(&matchpairs, ':\|,')
  let i = index(plist, c)
  if i < 0
    return
  endif
  if i % 2 == 0
    let s_flags = 'nW'
    let c2 = plist[i + 1]
  else
    let s_flags = 'nbW'
    let c2 = c
    let c = plist[i - 1]
  endif
  if c == '['
    let c = '\['
    let c2 = '\]'
  endif
  let s_skip ='synIDattr(synID(line("."), col("."), 0), "name") ' ..
        \ '=~?  "string\\|comment"'
  execute 'if' s_skip '| let s_skip = 0 | endif'

  let [m_lnum, m_col] = searchpairpos(c, '', c2, s_flags, s_skip)

  if m_lnum > 0 && m_lnum >= line('w0') && m_lnum <= line('w$')
    exe 'match Search /\(\%' .. c_lnum .. 'l\%' .. c_col ..
          \ 'c\)\|\(\%' .. m_lnum .. 'l\%' .. m_col .. 'c\)/'
    let s:paren_hl_on = 1
  endif
endfunction

autocmd CursorMoved,CursorMovedI * call s:Highlight_Matching_Paren()
autocmd InsertEnter * match none
```

Opening help in the current window

help-curwin

By default, help is displayed in a split window. If you prefer it opens in
the current window, try this custom :HelpCurwin command:

```
command -bar -nargs=? -complete=help HelpCurwin execute s:HelpCurwin(<q-args>)
let s:did_open_help = v:false

function s:HelpCurwin(subject) abort
  let mods = 'silent noautocmd keepalt'
  if !s:did_open_help
    execute mods .. ' help'
    execute mods .. ' helpclose'
    let s:did_open_help = v:true
  endif
  if !empty(getcompletion(a:subject, 'help'))
    execute mods .. ' edit ' .. &helpfile
    set buftype=help
  endif
  return 'help ' .. a:subject
endfunction
```

Treesitter integration

Nvim integrates the tree-sitter library for incremental parsing of buffers:
https://tree-sitter.github.io/tree-sitter/

WARNING: Treesitter support is still experimental and subject to frequent changes. This documentation may also not fully reflect the latest changes.

PARSER FILES

treesitter-parsers

Parsers are the heart of treesitter. They are libraries that treesitter will search for in the parser runtime directory.

Nvim includes these parsers:

- C
- Diff
- Lua
- Markdown
- Vimscript
- Vimdoc
- Treesitter query files ft-query-plugin

You can install more parsers manually, or with a plugin like
https://github.com/nvim-treesitter/nvim-treesitter .

Parsers are searched for as parser/{lang}.* in any 'runtimepath' directory. If multiple parsers for the same language are found, the first one is used. (NOTE: This typically implies the priority "user config > plugins > bundled".)

To load a parser from its filepath:

```
vim.treesitter.language.add('python', { path = "/path/to/python.so" })
```

Parser names are assumed to be lower case if the file system is case-sensitive.

To associate certain filetypes with a treesitter language (name of parser), use vim.treesitter.language.register(). For example, to use the xml treesitter parser for buffers with filetype svg or xslt, use:

```
vim.treesitter.language.register('xml', { 'svg', 'xslt' })
```

treesitter-parsers-wasm

If Nvim is built with ENABLE_WASMTIME, then wasm parsers can also be loaded:

```
vim.treesitter.language.add('python', { path = "/path/to/python.wasm" })
```

TREESITTER QUERIES

treesitter-query

Treesitter queries are a way to extract information about a parsed TSTree, e.g., for the purpose of highlighting. Briefly, a query consists of one or more patterns. A pattern is defined over node types in the syntax tree. A match corresponds to specific elements of the syntax tree which match a pattern. Patterns may optionally define captures and predicates. A capture allows you to associate names with a specific node in a pattern. A predicate adds arbitrary metadata and conditional data to a match.

Queries are written in a lisp-like language documented in
https://tree-sitter.github.io/tree-sitter/using-parsers/queries/1-syntax.html
Note: The predicates listed there differ from those Nvim supports. See treesitter-predicates for a complete list of predicates supported by Nvim.

Nvim looks for queries as *.scm files in a queries directory under runtimepath, where each file contains queries for a specific language and purpose, e.g., queries/lua/highlights.scm for highlighting Lua files. By default, the first query on runtimepath is used (which usually implies that user config takes precedence over plugins, which take precedence over queries bundled with Nvim). If a query should extend other queries instead of replacing them, use treesitter-query-modeline-extends.

The Lua interface is described at lua-treesitter-query.

TREESITTER QUERY PREDICATES **treesitter-predicates**

Predicates are special scheme nodes that are evaluated to conditionally capture nodes. For example, the eq? predicate can be used as follows:

```
((identifier) @variable.builtin
  (#eq? @variable.builtin "self"))
```

to only match identifier corresponding to the "self" text. Such queries can be used to highlight built-in functions or variables differently, for instance.

The following predicates are built in:

eq? treesitter-predicate-eq?

Match a string against the text corresponding to a node:

```
((identifier) @variable.builtin (#eq? @variable.builtin "self"))
((node1) @left (node2) @right (#eq? @left @right))
```

any-eq? treesitter-predicate-any-eq?

Like eq?, but for quantified patterns only one captured node must match.

match? treesitter-predicate-match?

vim-match? treesitter-predicate-vim-match?

Match a regexp against the text corresponding to a node:

```
((identifier) @constant (#match? @constant "^[A-Z_]+$"))
```

Note: The ^ and $ anchors will match the start and end of the node's text.

any-match? treesitter-predicate-any-match?

any-vim-match? treesitter-predicate-any-vim-match?

Like match?, but for quantified patterns only one captured node must match.

lua-match? treesitter-predicate-lua-match?

Match lua-patterns against the text corresponding to a node, similar to match?

any-lua-match? treesitter-predicate-any-lua-match?

Like lua-match?, but for quantified patterns only one captured node must match.

contains? treesitter-predicate-contains?

Match a string against parts of the text corresponding to a node:

```
((identifier) @foo (#contains? @foo "foo"))
((identifier) @foo-bar (#contains? @foo-bar "foo" "bar"))
```

any-contains? treesitter-predicate-any-contains?

Like contains?, but for quantified patterns only one captured node must match.

any-of? treesitter-predicate-any-of?

Match any of the given strings against the text corresponding to a node:

```
((identifier) @foo (#any-of? @foo "foo" "bar"))
```

This is the recommended way to check if the node matches one of many keywords, as it has been optimized for this.

has-ancestor? treesitter-predicate-has-ancestor?

Match any of the given node types against all ancestors of a node:

```
((identifier) @variable.builtin
  (#any-of? @variable.builtin "begin" "end")
  (#has-ancestor? @variable.builtin range_expression))
```

has-parent? treesitter-predicate-has-parent?

Match any of the given node types against the direct ancestor of a node:

```
(((field_expression
     (field_identifier) @method)) @_parent
 (#has-parent? @_parent template_method function_declarator))
```

treesitter-predicate-not

Each predicate has a not- prefixed predicate that is just the negation of
the predicate.

treesitter-predicate-all

treesitter-predicate-any

Queries can use quantifiers to capture multiple nodes. When a capture contains
multiple nodes, predicates match only if ALL nodes contained by the capture
match the predicate. Some predicates (eq?, match?, lua-match?,
contains?) accept an any- prefix to instead match if ANY of the nodes
contained by the capture match the predicate.

As an example, consider the following Lua code:

```
-- TODO: This is a
-- very long
-- comment (just imagine it)
```

using the following predicated query:

```
(((comment)+ @comment)
 (#match? @comment "TODO"))
```

This query will not match because not all of the nodes captured by @comment
match the predicate. Instead, use:

```
(((comment)+ @comment)
 (#any-match? @comment "TODO"))
```

Further predicates can be added via vim.treesitter.query.add_predicate().
Use vim.treesitter.query.list_predicates() to list all available predicates.

TREESITTER QUERY DIRECTIVES

treesitter-directives

Treesitter directives store metadata for a node or match and perform side
effects. For example, the set! directive sets metadata on the match or node:

```
((identifier) @foo (#set! type "parameter"))
```

The following directives are built in:

set!

treesitter-directive-set!

Sets key/value metadata for a specific match or capture. Value is
accessible as either metadata[key] (match specific) or
metadata[capture_id][key] (capture specific).

Parameters:
{capture_id} (optional)
{key}
{value}

Examples:

```
((identifier) @foo (#set! @foo kind "parameter"))
((node1) @left (node2) @right (#set! type "pair"))
((codeblock) @markup.raw.block (#set! priority 90))
```

offset!

treesitter-directive-offset!

Takes the range of the captured node and applies an offset. This will
set a new range in the form of a list like { {start_row}, {start_col},
{end_row}, {end_col} } for the captured node with capture_id as
metadata[capture_id].offset. This offset will be applied to the
range returned in vim.treesitter.get_range(). Useful for
treesitter-language-injections.

Parameters:
{capture_id}
{start_row}
{start_col}
{end_row}
{end_col}

Example:

```
((identifier) @constant (#offset! @constant 0 1 0 -1))
```

gsub!

treesitter-directive-gsub!

Transforms the content of the node using a lua-pattern. This will set
a new metadata[capture_id].text.

Parameters:
{capture_id}
{pattern}
{replacement}

Example:

```
(#gsub! @_node ".*%.(.*)" "%1")
```

trim! treesitter-directive-trim!

Trims whitespace from the node. Sets a new metadata[capture_id].range. Takes a capture ID and, optionally, four integers to customize trimming behavior (1 meaning trim, 0 meaning don't trim). When only given a capture ID, trims blank lines (lines that contain only whitespace, or are empty) from the end of the node (for backwards compatibility). Can trim all whitespace from both sides of the node if parameters are given.

Examples:

```
; only trim blank lines from the end of the node
; (equivalent to (#trim! @fold 0 0 1 0))
(#trim! @fold)

; trim blank lines from both sides of the node
(#trim! @fold 1 0 1 0)

; trim all whitespace around the node
(#trim! @fold 1 1 1 1)
```

Parameters:
{capture_id}
{trim_start_linewise}
{trim_start_charwise}
{trim_end_linewise} (default 1 if only given {capture_id})
{trim_end_charwise}

Further directives can be added via vim.treesitter.query.add_directive().
Use vim.treesitter.query.list_directives() to list all available directives.

TREESITTER QUERY MODELINES treesitter-query-modeline

Nvim supports to customize the behavior of the queries using a set of "modelines", that is comments in the queries starting with ;. Here are the currently supported modeline alternatives:

inherits: {lang}... treesitter-query-modeline-inherits

Specifies that this query should inherit the queries from {lang}. This will recursively descend in the queries of {lang} unless wrapped in parentheses: ({lang}).
Note: This is meant to be used to include queries from another language. If you want your query to extend the queries of the same language, use extends.

extends treesitter-query-modeline-extends

Specifies that this query should be used as an extension for the query, i.e. that it should be merged with the others.
Note: The order of the extensions, and the query that will be used as a base depends on your 'runtimepath' value.

Note: These modeline comments must be at the top of the query, but can be repeated, for example, the following two modeline blocks are both valid:

```
;; inherits: typescript,jsx
;; extends
```

```
;; extends
;;
;; inherits: css
```

TREESITTER SYNTAX HIGHLIGHTING treesitter-highlight

Syntax highlighting is specified through queries named highlights.scm, which match a TSNode in the parsed TSTree to a capture that can be assigned a highlight group. For example, the query

```
(parameters (identifier) @variable.parameter)
```

matches any identifier node inside a function parameters node to the capture named @variable.parameter. For example, for a Lua code

```
function f(foo, bar) end
```

which will be parsed as (see :InspectTree):

```
(function_declaration ; [1:1 - 24]
  name: (identifier) ; [1:10 - 10]
  parameters: (parameters ; [1:11 - 20]
    name: (identifier) ; [1:12 - 14]
    name: (identifier))) ; [1:17 - 19]
```

the above query will highlight foo and bar as @variable.parameter.

It is also possible to match literal expressions (provided the parser returns them):

```
[
  "if"
  "else"
] @keyword.conditional
```

Assuming a suitable parser and highlights.scm query is found in runtimepath, treesitter highlighting for the current buffer can be enabled simply via vim.treesitter.start().

treesitter-highlight-groups

The capture names, prefixed with @, are directly usable as highlight groups. For many commonly used captures, the corresponding highlight groups are linked to Nvim's standard highlight-groups by default (e.g., @comment links to Comment) but can be overridden in colorschemes.

A fallback system is implemented, so that more specific groups fallback to more generic ones. For instance, in a language that has separate doc comments (e.g., c, java, etc.), @comment.documentation could be used. If this group is not defined, the highlighting for an ordinary @comment is used. This way, existing color schemes already work out of the box, but it is possible to add more specific variants for queries that make them available.

As an additional rule, capture highlights can always be specialized by language, by appending the language name after an additional dot. For instance, to highlight comments differently per language:

```
hi @comment.c guifg=Blue
hi @comment.lua guifg=DarkBlue
hi link @comment.documentation.java String
```

The following is a list of standard captures used in queries for Nvim, highlighted according to the current colorscheme (use :Inspect on one to see the exact definition):

```
@variable                       various variable names
@variable.builtin               built-in variable names (e.g. this, self)
@variable.parameter             parameters of a function
@variable.parameter.builtin     special parameters (e.g. _, it)
@variable.member                object and struct fields

@constant               constant identifiers
@constant.builtin       built-in constant values
@constant.macro         constants defined by the preprocessor

@module                 modules or namespaces
@module.builtin         built-in modules or namespaces
@label                  GOTO and other labels (e.g. label: in C), including heredoc labels

@string                 string literals
@string.documentation   string documenting code (e.g. Python docstrings)
@string.regexp          regular expressions
@string.escape          escape sequences
@string.special         other special strings (e.g. dates)
@string.special.symbol  symbols or atoms
@string.special.path    filenames
@string.special.url     URIs (e.g. hyperlinks)

@character              character literals
@character.special      special characters (e.g. wildcards)

@boolean                boolean literals
@number                 numeric literals
@number.float           floating-point number literals

@type                   type or class definitions and annotations
@type.builtin           built-in types
@type.definition        identifiers in type definitions (e.g. typedef <type> <identifier> in C)

@attribute              attribute annotations (e.g. Python decorators, Rust lifetimes)
@attribute.builtin      builtin annotations (e.g. @property in Python)
@property               the key in key/value pairs

@function               function definitions
@function.builtin       built-in functions
@function.call          function calls
@function.macro         preprocessor macros

@function.method        method definitions
@function.method.call   method calls

@constructor            constructor calls and definitions
@operator               symbolic operators (e.g. +, *)

@keyword                keywords not fitting into specific categories
@keyword.coroutine      keywords related to coroutines (e.g. go in Go, async/await in Python)
@keyword.function       keywords that define a function (e.g. func in Go, def in Python)
@keyword.operator       operators that are English words (e.g. and, or)
@keyword.import         keywords for including or exporting modules (e.g. import, from in Python)
@keyword.type           keywords describing namespaces and composite types (e.g. struct, enum)
@keyword.modifier       keywords modifying other constructs (e.g. const, static, public)
@keyword.repeat         keywords related to loops (e.g. for, while)
@keyword.return         keywords like return and yield
@keyword.debug          keywords related to debugging
@keyword.exception      keywords related to exceptions (e.g. throw, catch)

@keyword.conditional         keywords related to conditionals (e.g. if, else)
@keyword.conditional.ternary ternary operator (e.g. ?, :)
```

```
@keyword.directive           various preprocessor directives and shebangs
@keyword.directive.define    preprocessor definition directives

@punctuation.delimiter  delimiters (e.g. ;, ., ,)
@punctuation.bracket    brackets (e.g. (), {}, [])
@punctuation.special    special symbols (e.g. {} in string interpolation)

@comment                line and block comments
@comment.documentation  comments documenting code

@comment.error          error-type comments (e.g. ERROR, FIXME, DEPRECATED)
@comment.warning        warning-type comments (e.g. WARNING, FIX, HACK)
@comment.todo           todo-type comments (e.g. TODO, WIP)
@comment.note           note-type comments (e.g. NOTE, INFO, XXX)

@markup.strong          bold text
@markup.italic          italic text
@markup.strikethrough   struck-through text
@markup.underline       underlined text (only for literal underline markup!)

@markup.heading         headings, titles (including markers)
@markup.heading.1       top-level heading
@markup.heading.2       section heading
@markup.heading.3       subsection heading
@markup.heading.4       and so on
@markup.heading.5       and so forth
@markup.heading.6       six levels ought to be enough for anybody

@markup.quote           block quotes
@markup.math            math environments (e.g. $ ... $ in LaTeX)

@markup.link            text references, footnotes, citations, etc.
@markup.link.label      link, reference descriptions
@markup.link.url        URL-style links

@markup.raw             literal or verbatim text (e.g. inline code)
@markup.raw.block       literal or verbatim text as a stand-alone block

@markup.list            list markers
@markup.list.checked    checked todo-style list markers
@markup.list.unchecked  unchecked todo-style list markers

@diff.plus              added text (for diff files)
@diff.minus             deleted text (for diff files)
@diff.delta             changed text (for diff files)

@tag                    XML-style tag names (e.g. in XML, HTML, etc.)
@tag.builtin            builtin tag names (e.g. HTML5 tags)
@tag.attribute          XML-style tag attributes
@tag.delimiter          XML-style tag delimiters
```

treesitter-highlight-spell

The special @spell capture can be used to indicate that a node should be spell checked by Nvim's builtin spell checker. For example, the following capture marks comments as to be checked:

```
(comment) @spell
```

There is also @nospell which disables spellchecking regions with @spell.

treesitter-highlight-conceal

Treesitter highlighting supports conceal via the conceal and conceal_lines metadata. By convention, nodes to be concealed are captured as @conceal, but any capture can be used. For example, the following query can be used to hide code block delimiters in Markdown:

```
((fenced_code_block_delimiter) @conceal (#set! conceal ""))
```

It is also possible to replace a node with a single character, which (unlike legacy syntax) can be given a custom highlight. For example, the following (ill-advised) query replaces the != operator by a Unicode glyph, which is still highlighted the same as other operators:

```
"!=" @operator (#set! conceal "≠")
```

To conceal an entire line (do not draw it at all), a query with conceal_lines metadata can be used:

```
((comment) @comment @spell
  (#set! conceal_lines ""))
```

Conceals specified in this way respect 'conceallevel' and 'concealcursor'.

Note that although you can use any string for conceal, only the first character will be used:

```
; identifiers will be concealed with 'f'.
((identifier) @conceal (#set! conceal "foo"))
```

To remove a conceal highlight, you can use the @noconceal capture to override any existing conceal highlight set for the range.

```
((identifier) @noconceal)
```

treesitter-highlight-priority

Treesitter uses nvim_buf_set_extmark() to set highlights with a default priority of 100. This enables plugins to set a highlighting priority lower or higher than treesitter. It is also possible to change the priority of an individual query pattern manually by setting its "priority" metadata attribute:

```
((super_important_node) @superimportant (#set! priority 105))
```

treesitter-highlight-commentstring

Treesitter highlighting supports finer-grained 'commentstring's, used by the built-in commenting plugin. When the cursor is within a node that sets the bo.commentstring metadata property (treesitter-directive-set!), that property defines the comment delimiter (where "innermost wins"). This is useful for languages like JSX that have different comment syntax depending on the code region, for example:

```
((jsx_element) @_tag (#set! @_tag bo.commentstring "{/* %s */}"))
```

When multiple captures set this metadata over a region, only the innermost (most specific) one is applied to a given area.

TREESITTER LANGUAGE INJECTIONS

treesitter-language-injections

Note the following information is adapted from:
https://tree-sitter.github.io/tree-sitter/3-syntax-highlighting.html#language-injection

Some source files contain code written in multiple different languages. Examples include:

- HTML files, which can contain JavaScript inside of <script> tags and CSS inside of <style> tags
- ERB files, which contain Ruby inside of <% %> tags, and HTML outside of those tags
- PHP files, which can contain HTML between the <php tags
- JavaScript files, which contain regular expression syntax within regex literals
- Ruby, which can contain snippets of code inside of heredoc literals, where the heredoc delimiter often indicates the language
- Lua, which can contain snippets of Vimscript inside vim.cmd() calls.
- Vimscript, which can contain snippets of Lua inside :lua-heredoc blocks.

All of these examples can be modeled in terms of a parent syntax tree and one or more injected syntax trees, which reside inside of certain nodes in the parent tree. The language injection query allows you to specify these “injections” using the following captures:

- @injection.content - indicates that the captured node should have its contents re-parsed using another language. If there are multiple @injection.content captures in one pattern, all ranges will be collected and parsed as one tree. This allows query authors to create "scoped" injections with injection query quantifiers.
- @injection.language - indicates that the captured node’s text may contain the name of a language that should be used to re-parse the @injection.content.
- @injection.filename - indicates that the captured node’s text may contain a filename; the corresponding filetype is then looked-up up via vim.filetype.match() and treated as the name of a language that should be used to re-parse the @injection.content.

The language injection behavior can also be configured by some properties associated with patterns:

- injection.language - can be used to hard-code the name of a specific

language.
- injection.combined - indicates that all of the matching nodes in the tree should have their content parsed as one nested document.
- injection.include-children - indicates that the @injection.content node's entire text should be re-parsed, including the text of its child nodes. By default, child nodes' text will be excluded from the injected document.
- injection.self - indicates that the node's text should be parsed with the same language as the node's LanguageTree.
- injection.parent - indicates that the captured node's text should be parsed with the same language as the node's parent LanguageTree.

Injection queries are currently run over the entire buffer, which can be slow for large buffers. To disable injections for, e.g., c, just place an empty queries/c/injections.scm file in your 'runtimepath'.

DEFAULTS

treesitter-defaults

treesitter-incremental-selection

v_an

an — Selects [count]th parent node.
If buffer has no treesitter parser, falls back to vim.lsp.buf.selection_range().

v_in

in — Selects [count]th previous (or first) child node.
If buffer has no treesitter parser, falls back to vim.lsp.buf.selection_range().

v_]n

]n — Selects [count]th next node.

v_[n

[n — Selects [count]th previous node.

v_]N

]N — Expands selection to [count]th next node.

v_[N

[N — Expands selection to [count]th previous node.

VIM.TREESITTER

lua-treesitter **vim.treesitter**

The remainder of this document is a reference manual for the vim.treesitter Lua module, which is the main interface for Nvim's treesitter integration. Most of the following content is automatically generated from the function documentation.

vim.treesitter.language_version

The latest parser ABI version that is supported by the bundled treesitter library.

vim.treesitter.minimum_language_version

The earliest parser ABI version that is supported by the bundled treesitter library.

TREESITTER TREES

treesitter-tree **TSTree**

A "treesitter tree" represents the parsed contents of a buffer, which can be used to perform further analysis. It is a userdata reference to an object held by the treesitter library.

An instance TSTree of a treesitter tree supports the following methods.

TSTree:copy()

TSTree:copy()

Returns a copy of the TSTree.

Return:
(TSTree)

TSTree:root()

TSTree:root()

Return the root node of this tree.

Return:
(TSNode)

TREESITTER NODES

treesitter-node **TSNode**

A "treesitter node" represents one specific element of the parsed contents of a buffer, which can be captured by a treesitter-query for, e.g., highlighting. It is a userdata reference to an object held by the treesitter library.

An instance TSNode of a treesitter node supports the following methods.

TSNode:byte_length() TSNode:byte_length()

Return the number of bytes spanned by this node.

Return:
(integer)

TSNode:child({index}) TSNode:child()

Get the node's child at the given {index}, where zero represents the first child.

Parameters:
- {index} (integer)

Return:
(TSNode?)

TSNode:child_count() TSNode:child_count()

Get the node's number of children.

Return:
(integer)

TSNode:child_with_descendant()

TSNode:child_with_descendant({descendant})
Get the node's child that contains {descendant} (includes {descendant}).

For example, with the following node hierarchy:

```
a -> b -> c

a:child_with_descendant(c) == b
a:child_with_descendant(b) == b
a:child_with_descendant(a) == nil
```

Parameters:
- {descendant} (TSNode)

Return:
(TSNode?)

TSNode:descendant_for_range()

TSNode:descendant_for_range({start_row}, {start_col}, {end_row}, {end_col})
Get the smallest node within this node that spans the given range of (row, column) positions

Parameters:
- {start_row} (integer)
- {start_col} (integer)
- {end_row} (integer)
- {end_col} (integer)

Return:
(TSNode?)

TSNode:end_() TSNode:end_()

Get the node's end position. Return three values: the row, column and total byte count (all zero-based).

Return (multiple):
(integer)
(integer)
(integer)

TSNode:equal({node}) TSNode:equal()

Check if {node} refers to the same node within the same tree.

Parameters:
- {node} (TSNode)

Return:

(boolean)

TSNode:extra() TSNode:extra()

Check if the node is extra. Extra nodes represent things like comments, which are not required by the grammar but can appear anywhere.

Return:
(boolean)

TSNode:field({name}) TSNode:field()

Returns a list of all the node's children that have the given field name.

Parameters:
- {name} (string)

Return:
(TSNode[])

TSNode:has_changes() TSNode:has_changes()

Check if a syntax node has been edited.

Return:
(boolean)

TSNode:has_error() TSNode:has_error()

Check if the node is a syntax error or contains any syntax errors.

Return:
(boolean)

TSNode:id() TSNode:id()

Get a unique identifier for the node inside its own tree.

No guarantees are made about this identifier's internal representation, except for being a primitive Lua type with value equality (so not a table). Presently it is a (non-printable) string.

Note: The id is not guaranteed to be unique for nodes from different trees.

Return:
(string)

TSNode:iter_children() TSNode:iter_children()

Iterates over all the direct children of {TSNode}, regardless of whether they are named or not. Returns the child node plus the eventual field name corresponding to this child node.

Return:
(fun(): TSNode, string)

TSNode:missing() TSNode:missing()

Check if the node is missing. Missing nodes are inserted by the parser in order to recover from certain kinds of syntax errors.

Return:
(boolean)

TSNode:named() TSNode:named()

Check if the node is named. Named nodes correspond to named rules in the grammar, whereas anonymous nodes correspond to string literals in the grammar.

Return:
(boolean)

TSNode:named_child({index}) TSNode:named_child()

Get the node's named child at the given {index}, where zero represents the first named child.

Parameters:
- {index} (integer)

Return:
(TSNode?)

TSNode:named_child_count() TSNode:named_child_count()

Get the node's number of named children.

Return:
(integer)

TSNode:named_children() TSNode:named_children()

Returns a list of the node's named children.

Return:
(TSNode[])

TSNode:named_descendant_for_range()

TSNode:named_descendant_for_range({start_row}, {start_col}, {end_row},
                                  {end_col})
    Get the smallest named node within this node that spans the given range of
    (row, column) positions

Parameters:
- {start_row} (integer)
- {start_col} (integer)
- {end_row}   (integer)
- {end_col}   (integer)

Return:
        (TSNode?)

TSNode:next_named_sibling() TSNode:next_named_sibling()

    Get the node's next named sibling.

Return:
        (TSNode?)

TSNode:next_sibling() TSNode:next_sibling()

    Get the node's next sibling.

Return:
        (TSNode?)

TSNode:parent() TSNode:parent()

    Get the node's immediate parent. Prefer TSNode:child_with_descendant()
    for iterating over the node's ancestors.

Return:
        (TSNode?)

TSNode:prev_named_sibling() TSNode:prev_named_sibling()

    Get the node's previous named sibling.

Return:
        (TSNode?)

TSNode:prev_sibling() TSNode:prev_sibling()

    Get the node's previous sibling.

Return:
        (TSNode?)

TSNode:range({include_bytes}) TSNode:range()

    Get the range of the node.

    Return four or six values:
- start row
- start column
- start byte (if {include_bytes} is true)
- end row
- end column
- end byte (if {include_bytes} is true)

Parameters:
- {include_bytes} (false?)

Overloads:
- fun(self: TSNode, include_bytes: true): integer, integer, integer, integer, integer, integer

Return (multiple):
        (integer)
        (integer)
        (integer)
        (integer)

TSNode:sexpr() TSNode:sexpr()

Get an S-expression representing the node as a string.

Return:
(string)

TSNode:start() TSNode:start()

Get the node's start position. Return three values: the row, column and total byte count (all zero-based).

Return (multiple):
(integer)
(integer)
(integer)

TSNode:symbol() TSNode:symbol()

Get the node's type as a numerical id.

Return:
(integer)

TSNode:tree() TSNode:tree()

Get the TSTree of the node.

Return:
(TSTree)

TSNode:type() TSNode:type()

Get the node's type as a string.

Return:
(string)

Lua module: vim.treesitter lua-treesitter-core

foldexpr({lnum}) vim.treesitter.foldexpr()

Returns the fold level for {lnum} in the current buffer. Can be set directly to 'foldexpr':

```
vim.wo.foldexpr = vim.treesitter.foldexpr
```

Attributes:
Since: 0.9.0

Parameters:
- {lnum} (integer?) Line number to calculate fold level for

Return:
(string)

get_captures({buf}, {start}, {stop}) vim.treesitter.get_captures()

Returns highlight captures at a position, on a line, or overlapping a range.

{start} and {stop} can be a row number or a {row, col} pair. All rows and columns are 0-based; columns are byte offsets.

Without {stop}, a row number queries the whole line and a {row, col} pair queries one position.

With {stop}, return captures that overlap the range. The stop position is excluded; a row number excludes that row. Empty ranges return no captures.

Each result includes the full captured node range, which may extend outside the requested range. Returns an empty list if treesitter highlighting is not active in {buf}.

Attributes:
Since: 0.13.0

Parameters:
- {buf} (integer) Buffer number (0 for current buffer)
- {start} (integer|[integer,integer]) Start row or {row, col}
- {stop} (integer|[integer,integer]?) Stop row or {row, col}

(excluded)

Return:
(table[]) A list of objects with the following fields:
- {capture} (string) Capture name
- {col} (integer) Start column
- {end_col} (integer) End column (excluded)

- {end_row} (integer) End row
- {id} (integer) 1-based capture id in the query
- {lang} (string) Language name
- {metadata} (vim.treesitter.query.TSMetadata) Query metadata, e.g.

  priority or conceal
- {pattern_id} (integer) 1-based id of the matched pattern in the

  query
- {row} (integer) Start row

get_captures_at_cursor({win}) vim.treesitter.get_captures_at_cursor()

Returns a list of highlight capture names under the cursor

Parameters:
- {win} (integer?) window-ID or 0 for current window (default)

Return:

(string[]) List of capture names

get_node({opts}) vim.treesitter.get_node()

Returns the smallest named node at the given position

NOTE: Calling this on an unparsed tree can yield an invalid node. If the tree is not known to be parsed by, e.g., an active highlighter, parse the tree first via

```
vim.treesitter.get_parser(bufnr):parse(range)
```

Parameters:
- {opts} (table?) Optional keyword arguments:
  - {bufnr} (integer?) Buffer number (nil or 0 for current

    buffer)
  - {ignore_injections} (boolean?, default: true) Ignore

    injected languages
  - {include_anonymous} (boolean?, default: false) Include

    anonymous nodes
  - {lang} (string?, default: from 'filetype') Parser

    language.
  - {pos} ([integer, integer]?, default: window-local cursor)

    0-indexed (row, col) tuple. Required if {bufnr} is not the current buffer

Return:

(TSNode?) Node at the given position

get_node_range({node_or_range}) vim.treesitter.get_node_range()

Returns the node's range or an unpacked range table

Parameters:
- {node_or_range} (TSNode|Range4) Node or table of positions

Return (multiple):

(integer) start_row
(integer) start_col (byte offset)
(integer) end_row
(integer) end_col (byte offset)

vim.treesitter.get_node_text()

get_node_text({node}, {source}, {opts})

Gets the text corresponding to a given node

Parameters:
- {node} (TSNode)

- {source} (integer|string) Buffer or string from which the {node} is extracted
- {opts} (table?) Optional parameters.
  - metadata (table) Metadata of a specific capture. This would be set to metadata[capture_id] when using vim.treesitter.query.add_directive().

Return:
(string)

get_parser({buf}, {lang}, {opts}) vim.treesitter.get_parser()

Returns the parser for a specific buffer and attaches it to the buffer

If needed, this will create the parser.

If no parser can be created, nil (and an error message) is returned.

Parameters:
- {buf} (integer?) (default: current buffer) Buffer the parser should be tied to
- {lang} (string?) (default: from 'filetype') Language of this parser
- {opts} (table?) Options to pass to the created language tree

Return (multiple):
(vim.treesitter.LanguageTree?) object to use for parsing
(string?) error message, if applicable

get_range({node}, {source}, {metadata}) vim.treesitter.get_range()

Get the range of a TSNode. Can also supply {source} and {metadata} to get the range with directives applied.

Parameters:
- {node} (TSNode)
- {source} (integer|string?) Buffer or string from which the {node} is extracted
- {metadata} (vim.treesitter.query.TSMetadata?)

Return:
(table) A table with the following fields:
- {[1]} (integer) start row
- {[2]} (integer) start column
- {[3]} (integer) start bytes
- {[4]} (integer) end row
- {[5]} (integer) end column
- {[6]} (integer) end bytes

vim.treesitter.get_string_parser()

get_string_parser({str}, {lang}, {opts})
Returns a string parser

Parameters:
- {str} (string) Text to parse
- {lang} (string) Language of this string
- {opts} (table?) Options to pass to the created language tree

Return:
(vim.treesitter.LanguageTree) object to use for parsing

inspect_tree({opts}) vim.treesitter.inspect_tree()

Open a window that displays a textual representation of the nodes in the language tree.

While in the window, press "a" to toggle display of anonymous nodes, "I" to toggle the display of the source language of each node, "o" to toggle the query editor, and press <Enter> to jump to the node under the cursor in the source buffer. Folding also works (try zo, zc, etc.).

Can also be shown with :InspectTree. :InspectTree

Attributes:
Since: 0.9.0

Parameters:
- {opts} (table?) Optional options table with the following possible keys:
  - bufnr (integer|nil): Buffer to draw the tree into. If omitted, a new buffer is created.
  - command (string|nil): Vimscript command to create the window. Default value is "60vnew". Only used when {winid} is nil.
  - lang (string|nil): The language of the source buffer. If omitted, detect from the filetype of the source buffer.
  - title (string|fun(bufnr:integer):string|nil): Title of the window. If a function, it accepts the buffer number of the source buffer as its only argument and should return a string.
  - winid (integer|nil): Window id to display the tree buffer in. If omitted, a new window is created with {command}.

is_ancestor({dest}, {source}) vim.treesitter.is_ancestor()

Determines whether a node is the ancestor of another

Parameters:
- {dest} (TSNode) Possible ancestor
- {source} (TSNode) Possible descendant

Return:
(boolean) True if {dest} is an ancestor of {source}

vim.treesitter.is_in_node_range()

is_in_node_range({node}, {line}, {col})
Determines whether (line, col) position is in node range

Parameters:
- {node} (TSNode) defining the range
- {line} (integer) Line (0-based)
- {col} (integer) Column (0-based)

Return:
(boolean) True if the position is in node range

node_contains({node}, {range}) vim.treesitter.node_contains()

Determines if a node contains a range

Parameters:
- {node} (TSNode)
- {range} (table)

Return:
(boolean) True if the {node} contains the {range}

select({target}, {count}) vim.treesitter.select()

Starts or adjusts a Visual selection at cursor, based on tree nodes. The target parameter decides the selection behavior.

Parameters:
- {target} ('parent'|'child'|'next'|'prev'|'extend_next'|'extend_prev')

  Decides the selection behavior.
- {count} (integer?) (default: 1) Expand or adjust the selection

  this many times.

start({buf}, {lang}) vim.treesitter.start()

Starts treesitter highlighting for a buffer

Can be used in an ftplugin or FileType autocommand.

Note: By default, disables regex syntax highlighting, which may be required for some plugins. In this case, add vim.bo.syntax = 'ON' after the call to start.

Note: By default, the highlighter parses code asynchronously, using a segment time of 3ms.

Example:

```
vim.api.nvim_create_autocmd( 'FileType', { pattern = 'tex',
    callback = function(ev)
        vim.treesitter.start(ev.buf, 'latex')
        vim.bo[ev.buf].syntax = 'ON'  -- only if additional legacy syntax is needed
    end
})
```

Parameters:
- {buf} (integer?) (default: current buffer) Buffer to be

  highlighted
- {lang} (string?) (default: from 'filetype') Language of the parser

stop({buf}) vim.treesitter.stop()

Stops treesitter highlighting for a buffer

Parameters:
- {buf} (integer?) (default: current buffer) Buffer to stop

  highlighting

Lua module: vim.treesitter.language treesitter-language

add({lang}, {opts}) vim.treesitter.language.add()

Load parser with name {lang}

Parsers are searched in the parser runtime directory, or the provided {path}. Can be used to check for available parsers before enabling treesitter features, e.g.,

```
if vim.treesitter.language.add('markdown') then
  vim.treesitter.start(bufnr, 'markdown')
end
```

Parameters:
- {lang} (string) Name of the parser (alphanumerical and _ only)
- {opts} (table?) Options:
  - {path}? (string) Optional path the parser is located at
  - {symbol_name}? (string) Internal symbol name for the

    language to load

Return (multiple):
(boolean?) True if parser is loaded
(string?) Error if parser cannot be loaded

get_filetypes({lang}) vim.treesitter.language.get_filetypes()

Returns the filetypes for which a parser named {lang} is used.

The list includes {lang} itself plus all filetypes registered via vim.treesitter.language.register().

Parameters:
- {lang} (string) Name of parser

Return:

(string[]) filetypes

get_lang({filetype}) vim.treesitter.language.get_lang()

Returns the language name to be used when loading a parser for {filetype}.

If no language has been explicitly registered via vim.treesitter.language.register(), default to {filetype}. For composite filetypes like html.glimmer, only the main filetype is returned.

Parameters:
- {filetype} (string)

Return:
(string?)

inspect({lang}) vim.treesitter.language.inspect()

Inspects the provided language.

Inspecting provides some useful information on the language like ABI version, parser state count (a measure of parser complexity), node and field names, and whether the language came from a WASM module.

Node names are returned in a table mapping each node name to a boolean indicating whether or not the node is named (i.e., not anonymous). Anonymous nodes are surrounded with double quotes (").

For ABI 15 parsers, also show parser metadata (major, minor, patch version) and a table of supertypes with their respective subtypes.

Parameters:
- {lang} (string) Language

Return:
(TSLangInfo)

register({lang}, {filetype}) vim.treesitter.language.register()

Register a parser named {lang} to be used for {filetype}(s).

Note: this adds or overrides the mapping for {filetype}, any existing mappings from other filetypes to {lang} will be preserved.

Parameters:
- {lang} (string) Name of parser
- {filetype} (string|string[]) Filetype(s) to associate with lang

Lua module: vim.treesitter.languagetree treesitter-languagetree

A LanguageTree contains a tree of parsers: the root treesitter parser for {lang} and any "injected" language parsers, which themselves may inject other languages, recursively. For example a Lua buffer containing some Vimscript commands needs multiple parsers to fully understand its contents.

To create a LanguageTree (parser object) for a given buffer and language, use:

```
local parser = vim.treesitter.get_parser(bufnr, lang)
```

(where bufnr=0 means current buffer). lang defaults to 'filetype'. **Note:** currently the parser is retained for the lifetime of a buffer but this may change; a plugin should keep a reference to the parser object if it wants incremental updates.

Whenever you need to access the current syntax tree, parse the buffer:

```
local tree = parser:parse({ start_row, end_row })
```

This returns a table of immutable treesitter-tree objects representing the current state of the buffer. When the plugin wants to access the state after a (possible) edit it must call parse() again. If the buffer wasn't edited, the same tree will be returned again without extra work. If the buffer was parsed before, incremental parsing will be done of the changed parts.

Note: To use the parser directly inside a nvim_buf_attach() Lua callback, you must call vim.treesitter.get_parser() before you register your callback. But preferably parsing shouldn't be done directly in the change callback anyway as they will be very frequent. Rather a plugin that does any kind of analysis on a tree should use a timer to throttle too frequent updates.

LanguageTree:children() LanguageTree:children()

Returns a map of language to child tree.

Return:
(table<string,vim.treesitter.LanguageTree>)

LanguageTree:contains({range}) LanguageTree:contains()

Determines whether {range} is contained in the LanguageTree.

Parameters:

- {range} (table) A table with the following fields:
    - {[1]} (integer) start row
    - {[2]} (integer) start column
    - {[3]} (integer) end row
    - {[4]} (integer) end column

Return:
    (boolean)

LanguageTree:destroy() LanguageTree:destroy()

Destroys this LanguageTree and all its children.

Any cleanup logic should be performed here.

Note: This DOES NOT remove this tree from a parent. Instead, remove_child must be called on the parent to remove it.

LanguageTree:for_each_tree({fn}) LanguageTree:for_each_tree()

Invokes the callback for each LanguageTree recursively.

Note: This includes the invoking tree's child trees as well.

Parameters:
- {fn} (fun(tree: TSTree, ltree: vim.treesitter.LanguageTree))

LanguageTree:included_regions() LanguageTree:included_regions()

Gets the set of included regions managed by this LanguageTree. This can be different from the regions set by injection query, because a partial LanguageTree:parse() drops the regions outside the requested range. Each list represents a range in the form of { {start_row}, {start_col}, {start_bytes}, {end_row}, {end_col}, {end_bytes} }.

Return:
    (table<integer, Range6[]>)

LanguageTree:invalidate({reload}) LanguageTree:invalidate()

Invalidates this parser and its children.

Should only be called when the tracked state of the LanguageTree is not valid against the parse tree in treesitter. Doesn't clear filesystem cache. Called often, so needs to be fast.

Parameters:
- {reload} (boolean?)

LanguageTree:is_valid()

LanguageTree:is_valid({exclude_children}, {range})
Returns whether this LanguageTree is valid, i.e., LanguageTree:trees() reflects the latest state of the source. If invalid, user should call LanguageTree:parse().

Parameters:
- {exclude_children} (boolean?) whether to ignore the validity of children (default false)
- {range} (Range|Range[]?) range (or list of ranges, sorted by starting point in ascending order) to check for validity

Return:
    (boolean)

LanguageTree:lang() LanguageTree:lang()

Gets the language of this tree node.

Return:
    (string)

LanguageTree:language_for_range()

LanguageTree:language_for_range({range})
Gets the appropriate language that contains {range}.

Parameters:
- {range} (table) A table with the following fields:

- {[1]} (integer) start row
- {[2]} (integer) start column
- {[3]} (integer) end row
- {[4]} (integer) end column

Return:
(vim.treesitter.LanguageTree) tree Managing {range}

LanguageTree:named_node_for_range()

LanguageTree:named_node_for_range({range}, {opts})
Gets the smallest named node that contains {range}.

Parameters:
- {range} (table) A table with the following fields:
  - {[1]} (integer) start row
  - {[2]} (integer) start column
  - {[3]} (integer) end row
  - {[4]} (integer) end column
- {opts} (table?) A table with the following fields:
  - {ignore_injections}? (boolean, default: true) Ignore injected languages

Return:
(TSNode?)

LanguageTree:node_for_range()

LanguageTree:node_for_range({range}, {opts})
Gets the smallest node that contains {range}.

Parameters:
- {range} (table) A table with the following fields:
  - {[1]} (integer) start row
  - {[2]} (integer) start column
  - {[3]} (integer) end row
  - {[4]} (integer) end column
- {opts} (table?) A table with the following fields:
  - {ignore_injections}? (boolean, default: true) Ignore injected languages

Return:
(TSNode?)

LanguageTree:parent()

Returns the parent tree. nil for the root tree.

Return:
(vim.treesitter.LanguageTree?)

LanguageTree:parse({range}, {on_parse})

Recursively parse all regions in the language tree using treesitter-parsers for the corresponding languages and run injection queries on the parsed trees to determine whether child trees should be created and parsed.

Any region with empty range ({}, typically only the root tree) is always parsed; otherwise (typically injections) only if it intersects {range} (or

if {range} is true).

Parameters:

- {range} (boolean|Range|Range[]?) Parse this range (or list of ranges, sorted by starting point in ascending order) in the parser's source. Set to true to run a complete parse of the source (**Note:** Can be slow!) Set to false|nil to only parse regions with empty ranges (typically only the root tree without injections).
- {on_parse} (fun(err?: string, trees?: table<integer, TSTree>)?) Function invoked when parsing completes. When omitted, parsing is synchronous and always returns the trees. When provided and vim.g._ts_force_sync_parsing is not set, parsing will run asynchronously. The first argument to the function is a string representing the error type, in case of a failure (currently only possible for timeouts). The second argument is the list of trees returned by the parse (upon success), or nil if the parse timed out (determined by 'redrawtime').

  If parsing was still able to finish synchronously (within 3ms), parse() returns the list of trees. Otherwise, it returns nil.

Overloads:

- fun(self: vim.treesitter.LanguageTree, range?: boolean|Range|Range[]): table<integer, TSTree>

Return:

(table<integer, TSTree>?)

LanguageTree:register_cbs()

LanguageTree:register_cbs({cbs}, {recursive})

Registers callbacks for the LanguageTree.

Parameters:

- {cbs} (table<TSCallbackNameOn,function>) An nvim_buf_attach()-like table argument with the following handlers:
  - on_bytes : see nvim_buf_attach().
  - on_changedtree : a callback that will be called every time the tree has syntactical changes. It will be passed two arguments: a table of the ranges (as node ranges) that changed and the changed tree.
  - on_child_added : emitted when a child is added to the tree.
  - on_child_removed : emitted when a child is removed from the tree.
  - on_detach : emitted when the buffer is detached, see nvim_buf_detach_event. Takes one argument, the number of the buffer.
- {recursive} (boolean?) Apply callbacks recursively for all children. Any new children will also inherit the callbacks.

LanguageTree:source()

LanguageTree:source()

Returns the source content of the language tree (bufnr or string).

Return:

(integer|string)

LanguageTree:tree_for_range()

LanguageTree:tree_for_range({range}, {opts})

Gets the tree that contains {range}.

Parameters:

- {range} (table) A table with the following fields:
  - {[1]} (integer) start row

- {[2]} (integer) start column
- {[3]} (integer) end row
- {[4]} (integer) end column

- {opts} (table?) A table with the following fields:
  - {ignore_injections}? (boolean, default: true) Ignore injected languages

Return:
(TSTree?)

LanguageTree:trees() LanguageTree:trees()

Returns all trees of the regions parsed by this parser. Does not include child languages. The result is list-like if

- this LanguageTree is the root, in which case the result is empty or a singleton list; or
- the root LanguageTree is fully parsed.

Return:
(table<integer, TSTree>)

Lua module: vim.treesitter.query lua-treesitter-query

This Lua treesitter-query interface allows you to create queries and use them to parse text. See vim.treesitter.query.parse() for a working example.

TSQuery
Extends: userdata

Reference to an object held by the treesitter library that is used as a component of the vim.treesitter.Query for language feature support. See treesitter-query for more about queries or vim.treesitter.query.parse() for an example of how to obtain a query object.

Fields:
- {disable_capture} (fun(self: TSQuery, capture_name: string)) See TSQuery:disable_capture().
- {disable_pattern} (fun(self: TSQuery, pattern_index: integer)) See TSQuery:disable_pattern().

vim.treesitter.Query
Parsed query, see vim.treesitter.query.parse()

Fields:
- {captures} (string[]) list of (unique) capture names defined in query
- {has_combined_injections} (boolean) whether the query contains combined injections
- {has_conceal_line} (boolean) whether the query sets conceal_lines metadata
- {info} (vim.treesitter.QueryInfo) query context (e.g. captures, predicates, directives)
- {iter_captures} (fun(self: vim.treesitter.Query, node: TSNode, source: integer|string, start_row: integer?, end_row: integer?, opts: table?): fun(end_line: integer?, end_col: integer?): integer, TSNode, vim.treesitter.query.TSMetadata, TSQueryMatch, TSTree) See Query:iter_captures().
- {iter_matches} (fun(self: vim.treesitter.Query, node: TSNode, source: integer|string, start: integer?, stop: integer?, opts: table?): fun(): integer, table<integer, TSNode[]>, vim.treesitter.query.TSMetadata, TSTree) See Query:iter_matches().
- {lang} (string) parser language name

- {query} (TSQuery) userdata query object

vim.treesitter.query.add_directive()

add_directive({name}, {handler}, {opts})
    Adds a new directive to be used in queries

    Handlers can set match level data by setting directly on the metadata
    object metadata.key = value. Additionally, handlers can set node level
    data by using the capture id on the metadata table
    metadata[capture_id].key = value

Parameters:
- {name} (string) Name of the directive, without leading #

- {handler} (fun(match: table<integer,TSNode[]>, pattern: integer, source: integer|string, predicate: any[], metadata: vim.treesitter.query.TSMetadata))

    - match: A table mapping capture IDs to a list of captured nodes
    - pattern: the index of the matching pattern in the query
    - predicate: list of strings containing the full directive file being called, e.g. (node (#set! conceal "-")) would get the predicate { "#set!", "conceal", "-" }
- {opts} (table) A table with the following fields:

    - {force}? (boolean) Override an existing predicate of the same name

vim.treesitter.query.add_predicate()

add_predicate({name}, {handler}, {opts})
    Adds a new predicate to be used in queries

Parameters:
- {name} (string) Name of the predicate, without leading #

- {handler} (fun(match: table<integer,TSNode[]>, pattern: integer, source: integer|string, predicate: any[], metadata: vim.treesitter.query.TSMetadata): boolean?)

    - see vim.treesitter.query.add_directive() for argument meanings
- {opts} (table?) A table with the following fields:

    - {force}? (boolean) Override an existing predicate of the same name

edit({lang}) vim.treesitter.query.edit()

    Opens a live editor to query the buffer you started from.

    Can also be shown with the :EditQuery command. :EditQuery <tab>
    completes available parsers.

    If you move the cursor to a capture name ("@foo"), text matching the
    capture is highlighted with hl-DiagnosticVirtualTextHint in the source
    buffer. The query editor is a scratch buffer, use :write to save it. You
    can find example queries at $VIMRUNTIME/queries/.

Parameters:
- {lang} (string?) language to open the query editor for. If omitted, inferred from the current buffer's filetype.

get({lang}, {query_name}) vim.treesitter.query.get()

    Returns the runtime query {query_name} for {lang}.

Parameters:
- {lang} (string) Language to use for the query

- {query_name} (string) Name of the query (e.g. "highlights")

Return:
(vim.treesitter.Query?) Parsed query. nil if no query files are found.

vim.treesitter.query.get_files()

get_files({lang}, {query_name}, {is_included})
Gets the list of files used to make up a query

Parameters:
- {lang} (string) Language to get query for
- {query_name} (string) Name of the query to load (e.g., "highlights")
- {is_included} (boolean?) Internal parameter, most of the time left as nil

Return:
(string[]) query_files List of files to load for given query and language

lint({buf}, {opts}) vim.treesitter.query.lint()

Lint treesitter queries using installed parser, or clear lint errors.

Use treesitter-parsers in runtimepath to check the query file in {buf} for errors:
- verify that used nodes are valid identifiers in the grammar.
- verify that predicates and directives are valid.
- verify that top-level s-expressions are valid.

The found diagnostics are reported using diagnostic-api. By default, the parser used for verification is determined by the containing folder of the query file, e.g., if the path ends in /lua/highlights.scm, the parser for the lua language will be used.

Parameters:
- {buf} (integer) Buffer handle
- {opts} (table?) Optional keyword arguments:
  - {clear}? (boolean) Just clear current lint errors
  - {langs}? (string|string[]) Language(s) to use for checking the query. If multiple languages are specified, queries are validated for all of them

list_directives() vim.treesitter.query.list_directives()

Lists the currently available directives to use in queries.

Return:
(string[]) Supported directives.

list_predicates() vim.treesitter.query.list_predicates()

Lists the currently available predicates to use in queries.

Return:
(string[]) Supported predicates.

omnifunc({findstart}, {base}) vim.treesitter.query.omnifunc()

Omnifunc for completing node names and predicates in treesitter queries.

Use via

```
vim.bo.omnifunc = vim.treesitter.query.omnifunc
```

Parameters:
- {findstart} (0|1)
- {base} (string)

parse({lang}, {query}) vim.treesitter.query.parse()

Parses a {query} string and returns a Query object

(lua-treesitter-query), which can be used to search the tree for the query patterns (via Query:iter_captures(), Query:iter_matches()), or inspect/modify the query via these fields:

- captures: a list of unique capture names defined in the query (alias: info.captures).
- info.patterns: information about predicates.
- query: the underlying TSQuery which can be used to disable patterns or captures.

Example:

```
local query = vim.treesitter.query.parse('vimdoc', [[
  ; query
  ((h1) @str
    (#trim! @str 1 1 1 1))
]])
local tree = vim.treesitter.get_parser():parse()[1]
for id, node, metadata in query:iter_captures(tree:root(), 0) do
   -- Print the node name and source text.
   vim.print({node:type(), vim.treesitter.get_node_text(node, vim.api.nvim_get_current_buf())})
end
```

Parameters:

- {lang} (string) Language to use for the query
- {query} (string) Query text, in s-expr syntax

Return:

(vim.treesitter.Query) Parsed query

See also:

- vim.treesitter.query.get()

Query:iter_captures()

```
Query:iter_captures({node}, {source}, {start_row}, {end_row}, {opts})
```

Iterates over all captures from all matches in {node}.

{source} is required if the query contains predicates; then the caller must ensure to use a freshly parsed tree consistent with the current text of the buffer (if relevant). {start} and {stop} can be used to limit matches inside a row range (this is typically used with root node as the {node}, i.e., to get syntax highlight matches in the current viewport). When omitted, the {start} and {stop} row values are used from the given node.

The iterator returns four values:

1. the numeric id identifying the capture
2. the captured node
3. metadata from any directives processing the match
4. the match itself

Example: how to get captures by name:

```
for id, node, metadata, match in query:iter_captures(tree:root(), bufnr, first, last) do
  local name = query.captures[id] -- name of the capture in the query
  -- typically useful info about the node:
  local type = node:type() -- type of the captured node
  local row1, col1, row2, col2 = node:range() -- range of the capture
  -- ... use the info here ...
end
```

Note:

- Captures are only returned if the query pattern of a specific capture contained predicates.

Parameters:

- {node} (TSNode) under which the search will occur
- {source} (integer|string) Source buffer or string to extract

text from
- {start_row} (integer?) Starting line for the search. Defaults to

node:start().
- {end_row} (integer?) Stopping line for the search (end-inclusive,

unless stop_col is provided). Defaults to
node:end_().
- {opts} (table?) Optional keyword arguments:

  - end_col (integer) Stopping column for the search

(end-exclusive).
  - match_limit (integer) Set the maximum number of

in-progress matches (Default: none).
  - max_start_depth (integer) if non-zero, sets the maximum

start depth for each match. This is used to prevent
traversing too deep into a tree.
  - start_col (integer) Starting column for the search.

Return:
(fun(end_line: integer?, end_col: integer?): integer, TSNode, vim.treesitter.query.TSMetadata, TSQueryMatch, TSTree)
capture-id, capture-node, metadata, match, tree

Query:iter_matches()

Query:iter_matches({node}, {source}, {start}, {stop}, {opts})
Iterates the matches of self on a given range.

Iterate over all matches within a {node}. The arguments are the same as
for Query:iter_captures() but the iterated values are different: an
(1-based) index of the pattern in the query, a table mapping capture
indices to a list of nodes, and metadata from any directives processing
the match.

Example:

```
for pattern, match, metadata in cquery:iter_matches(tree:root(), bufnr, 0, -1) do
  for id, nodes in pairs(match) do
    local name = query.captures[id]
    for _, node in ipairs(nodes) do
      -- `node` was captured by the `name` capture in the match

      local node_data = metadata[id] -- Node level metadata
      -- ... use the info here ...
    end
  end
end
```

Parameters:
- {node} (TSNode) under which the search will occur

- {source} (integer|string) Source buffer or string to search

- {start} (integer?) Starting line for the search. Defaults to

node:start().
- {stop} (integer?) Stopping line for the search (end-exclusive).

Defaults to node:end_().
- {opts} (table?) Optional keyword arguments:

  - match_limit (integer) Set the maximum number of

in-progress matches (Default: none).
  - max_start_depth (integer) if non-zero, sets the maximum

start depth for each match. This is used to prevent
traversing too deep into a tree.

Return:
(fun(): integer, table<integer, TSNode[]>, vim.treesitter.query.TSMetadata, TSTree)
pattern-id, match, metadata, tree

set({lang}, {query_name}, {text}) vim.treesitter.query.set()

Sets the runtime query named {query_name} for {lang}

This allows users to override or extend any runtime files and/or configuration set by plugins.

For example, you could enable spellchecking of C identifiers with the following code:

```
vim.treesitter.query.set(
  'c',
  'highlights',
  [[;inherits c
  (identifier) @spell]]
)
```

Parameters:

- {lang} (string) Language to use for the query
- {query_name} (string) Name of the query (e.g., "highlights")
- {text} (string) Query text (unparsed).

TSQuery:disable_capture({capture_name}) TSQuery:disable_capture()

Disable a specific capture in this query; once disabled the capture cannot be re-enabled. {capture_name} should not include a leading "@".

Example: To disable the @variable.parameter capture from the vimdoc highlights query:

```
local query = vim.treesitter.query.get('vimdoc', 'highlights')
query.query:disable_capture("variable.parameter")
vim.treesitter.get_parser():parse()
```

Parameters:

- {capture_name} (string)

TSQuery:disable_pattern({pattern_index}) TSQuery:disable_pattern()

Disable a specific pattern in this query; once disabled the pattern cannot be re-enabled. The {pattern_index} for a particular match can be obtained with :Inspect!, or by reading the source of the query (i.e. from vim.treesitter.query.get_files()).

Example: To disable | links in vimdoc but keep other @markup.links highlighted:

```
local link_pattern = 9 -- from :Inspect!
local query = vim.treesitter.query.get('vimdoc', 'highlights')
query.query:disable_pattern(link_pattern)
local tree = vim.treesitter.get_parser():parse()[1]
```

Parameters:

- {pattern_index} (integer)

Terminal UI tui

By default when you run `nvim` (without --embed or --headless) it starts the builtin "terminal UI" (TUI). This default UI is optional: you can run Nvim as a "headless" server, or you can use a GUI.

Startup startup-tui startup-terminal

Nvim has a client-server architecture: by default when you run `nvim`, this starts the builtin UI client, which starts a `nvim --embed` server (child) process that the UI client connects to. After attaching to the server, the UI client calls nvim_set_client_info() (as recommended for all UIs dev-ui) and sets these fields on its channel:

```
client = {
  attributes = {
    license = 'Apache 2',
    pid = …,
    website = 'https://neovim.io',
  },
  name = 'nvim-tui',
  type = 'ui',
  version = { … },
},
-- Preserved across :restart.
detach = <false if the UI started the server, true after :detach!>,
```

Nvim guesses the terminal type when it starts (except in --embed and --headless modes). The $TERM environment variable is the primary hint that determines the terminal type.

terminfo E557 E558 E559 To display its user interface, Nvim reads a list of "terminal capabilities" from the system terminfo database (or builtin defaults if terminfo is not found). If that information is wrong, the screen may be messed up or keys may not be recognized.

The Unibilium library (used to read terminfo) allows you to override the system terminfo with one in the "$HOME/.terminfo/" directory. Building your own terminfo is usually as simple as running this:

```
curl -LO https://invisible-island.net/datafiles/current/terminfo.src.gz
gunzip terminfo.src.gz
tic -x terminfo.src
```

$NVIM_TERMDEFS

To override the builtin terminfo, set $NVIM_TERMDEFS to a JSON object whose keys correspond to one or more of the fields below, each of which will override its counterpart (if any) in the builtin terminfo. The system terminfo will be skipped entirely: only builtin definitions, plus the $NVIM_TERMDEFS overrides, will be used.

For example, to disable alternate screen, override the "reset the cursor style" sequence, and set the <Home> and <S-Home> sequences:

```
NVIM_TERMDEFS='{
  "enter_ca_mode": "",
  "exit_ca_mode": "",
  "reset_cursor_style": "\u001b[0 q",
  "key_home": ["\u001bOH", "\u001b[1;2H"]
}' nvim
```

Be careful when putting escape sequences in strings, as JSON uses unicode escapes like `\u001b`. For all available fields, see tui-termdefs.

$TERM

The $TERM environment variable must match the terminal you are using! Otherwise Nvim cannot know what sequences your terminal expects, and weird or sub-optimal behavior will result (scrolling quirks, wrong colors, etc.).

$TERM is also important because it is forwarded by SSH to the remote session, unlike most other environment variables.

```
For this terminal           Set $TERM to                 |builtin-terms|
-------------------------------------------------------------------------
ansi                        (unknown)                          Y
Ghostty                     ghostty, xterm-ghostty             Y
iTerm (original)            iterm, iTerm.app                   N
iTerm2 (new capabilities)   iterm2, iTerm2.app                 Y
Konsole                     konsole-256color                   N
libvte-based                vte, vte-256color                  Y
 (e.g. GNOME Terminal)      (aliases: gnome, gnome-256color)
Linux virtual terminal      linux, linux-256color              Y
PuTTY                       putty, putty-256color              Y
rxvt                        rxvt, rxvt-256color                Y
screen                      screen, screen-256color            Y
simple terminal (st)        st, st-256color                    Y
Terminal.app                nsterm                             N
tmux                        tmux, tmux-256color                Y
Windows/ConEmu              conemu                             Y
Windows/Cygwin-built Nvim   cygwin                             Y
Windows/Interix             interix                            Y
Windows/legacy console      win32con                           Y
Windows/VTP console         vtpcon                             Y
xterm or compatible         xterm, xterm-256color              Y
```

builtin-terms builtin_terms Nvim will map $TERM to a builtin entry according to the above table if:

- a terminfo database is not available on the system
- no terminfo entry found for the current detected terminal
- Nvim was built without terminfo support (`has('terminfo')==0`)

The builtin terminfo is not combined with any external terminfo database, nor can it be used in preference to one. You can thus entirely override any omissions or out-of-date information in the builtin terminfo database by supplying an external one with entries for the terminal type.

For example "TERM=putty-256color" will be mapped to the builtin "putty" entry. See also tui-colors.

Settings depending on terminal term-dependent-settings

If you want to set terminal-dependent options or mappings, you can do this in your init.vim. Example:

```
if $TERM =~ '^\(rxvt\|screen\|interix\|putty\)\(-.*\)\?$'
    set notermguicolors
elseif $TERM =~ '^\(tmux\|iterm\|vte\|gnome\)\(-.*\)\?$'
    set termguicolors
elseif $TERM =~ '^\(xterm\)\(-.*\)\?$'
    if $XTERM_VERSION != ''
        set termguicolors
    elseif $KONSOLE_PROFILE_NAME != ''
        set termguicolors
    elseif $VTE_VERSION != ''
        set termguicolors
    else
        set notermguicolors
    endif
elseif $TERM =~ ...
    ... and so forth ...
endif
```

scroll-region xterm-scroll-region Where possible, Nvim will use the terminal's ability to set a scroll region in order to redraw faster when a window is scrolled. If the terminal's terminfo description describes an ability to set top and bottom scroll margins, that is used.

This will not speed up scrolling in a window that is not the full width of the terminal. Xterm has an extra ability, not described by terminfo, to set left and right scroll margins as well. If Nvim detects that the terminal is Xterm, it will make use of this ability to speed up scrolling that is not the full width of the terminal.

tui-input

Historically, terminal emulators could not distinguish between certain control key modifiers and other keys. For example, <C-I> and <Tab> are represented in the same way, as are <Esc> and <C-[>, <CR> and <C-M>, and <NL> and <C-J>.

Modern terminal emulators are able to distinguish between these pairs of keys by encoding control modifiers differently. There are two common but distinct ways of doing this, known as "modifyOtherKeys" and "CSI u". Nvim supports both encoding methods and at startup will tell the terminal emulator that it understands these key encodings. If your terminal emulator supports it then this will allow you to map the key pairs listed above separately. <Tab>

Nvim uses libtermkey to convert terminal escape sequences to key codes. terminfo is used first, and CSI sequences not in terminfo (including extended keys a.k.a. "modifyOtherKeys" or "CSI u") can also be parsed.

For example, when running Nvim in tmux, this makes Nvim leave Insert mode and go to the window below:

```
tmux send-keys 'Escape' [ 2 7 u 'C-W' j
```

Where `'Escape' [ 2 7 u` is an unambiguous "CSI u" sequence for the <Esc> key.

The kitty keyboard protocol https://sw.kovidgoyal.net/kitty/keyboard-protocol/ is partially supported, including keypad keys in Unicode Private Use Area. For example, this sequence is recognized by Nvim as <C-kEnter>:

```
CSI 57414 ; 5 u
```

and can be used differently from <C-CR> in mappings.

tui-modifyOtherKeys tui-csiu At startup Nvim will query your terminal to see if it supports the "CSI u" encoding by writing the sequence

```
CSI ? u CSI c
```

If your terminal emulator responds with

```
CSI ? <flags> u
```

this means your terminal supports the "CSI u" encoding and Nvim will tell your terminal to enable it by writing the sequence

```
CSI > 3 u
```

If your terminal does not support "CSI u" then Nvim will instead enable the "modifyOtherKeys" encoding by writing the sequence

```
CSI > 4 ; 2 m
```

The "3" requests the kitty keyboard protocol "progressive enhancement" flags 1 (disambiguate escape codes) and 2 (report event types). Nvim does not request 8 (report all keys as escape codes) nor 16 (report associated text), which are needed to distinguish keys that produce the same text as their unmodified counterpart, such as <S-Space> and <Space>.

When Nvim exits cleanly it will send the corresponding sequence to disable the special key encoding. If Nvim does not exit cleanly then your terminal emulator could be in a bad state. If this happens, simply run "reset".

tui-colors

Nvim uses 256 colours by default, ignoring terminfo for most terminal types, including "linux" (whose virtual terminals have had 256-colour support since 4.8) and anything claiming to be "xterm". Also when $COLORTERM or $TERM contain the string "256".

Nvim similarly assumes that any terminal emulator that sets $COLORTERM to any value, is capable of at least 16-colour operation.

true-color xterm-true-color Nvim emits true (24-bit) colours in the terminal, if 'termguicolors' is set.

It uses the "setrgbf" and "setrgbb" terminfo extensions (proposed by Rüdiger Sonderfeld in 2013). If your terminfo definition is missing them, then Nvim will decide whether to add them to your terminfo definition, using the ISO 8613-6:1994/ITU T.416:1993 control sequences for setting RGB colours (but modified to use semicolons instead of colons unless the terminal is known to follow the standard).

Another convention, pioneered in 2016 by tmux, is the "Tc" terminfo extension. If terminfo has this flag, Nvim will add constructed "setrgbf" and "setrgbb" capabilities as if they had been in the terminfo definition.

If terminfo does not (yet) have this flag, Nvim will fall back to $TERM and other environment variables. It will add constructed "setrgbf" and "setrgbb" capabilities in the case of the "rxvt", "linux", "st", "tmux", and "iterm" terminal types, or when Konsole, genuine Xterm, a libvte terminal emulator version 0.36 or later, or a terminal emulator that sets the COLORTERM environment variable to "truecolor" is detected.

xterm-resize

Nvim can resize the terminal display on some terminals that implement an extension pioneered by dtterm. terminfo does not have a flag for this extension. So Nvim simply assumes that (all) "dtterm", "xterm", "teraterm", "rxvt" terminal types, and Konsole, are capable of this.

tui-cursor-shape

Nvim will adjust the shape of the cursor from a block to a line when in insert mode (or as specified by the 'guicursor' option), on terminals that support it. It uses the same terminfo extensions that were pioneered by tmux for this: "Ss" and "Se". Similarly, if you set the cursor highlight group with blend=100, Nvim hides the cursor through the "cvvis" and "civis" extensions.

If your terminfo definition is missing them, then Nvim will decide whether to add them to your terminfo definition, by looking at $TERM and other environment variables. For the "rxvt", "putty", "linux", "screen", "teraterm", and "iterm" terminal types, or when Konsole, a libvte-based terminal emulator, or genuine Xterm are detected, it will add constructed "Ss" and "Se" capabilities.

tui-cursor-tmux

Within tmux it may appear that Nvim is not changing the cursor, but in fact it is tmux receiving instructions from Nvim to change the cursor and not knowing what to do in turn. tmux must translate what it receives from Nvim into whatever control sequence is appropriate for the host terminal. It shares a common mechanism with Nvim, of using the "Ss" and "Se" capabilities from terminfo (for the output terminal) if they are present. Unlike Nvim, if they are not in terminfo you must add them by setting "terminal-overrides" in ~/.tmux.conf .

See the tmux(1) manual page for the details of how and what to do in the tmux configuration file. It will look something like:

```
set -ga terminal-overrides '*:Ss=\E[%p1%d q:Se=\E[ q'
```

or (alas!) for Konsole 18.07.70 or older, something more complex like:

```
set -ga terminal-overrides 'xterm*:\E]50;CursorShape=%?%p1%{3}%<%t%{0}%e%{1}%;%d\007'
```

Window size

window-size

[This is about the size of the whole window Vim is using, not a window that is created with the ":split" command.]

On Unix systems, three methods are tried to get the window size:

- an ioctl call (TIOCGSIZE or TIOCGWINSZ, depends on your system)
- the environment variables "LINES" and "COLUMNS"
- from the terminfo entries "lines" and "columns"

If everything fails a default size of 24 lines and 80 columns is assumed. If a window-resize signal is received the size will be set again. If the window size is wrong you can use the 'lines' and 'columns' options to set the correct values. See :mode.

Slow and fast terminals

slow-fast-terminal

slow-terminal

If you have a slow terminal you may want to reset the 'showcmd' and 'ruler' options. The command characters and cursor positions will not be shown in the status line (which involves a lot of cursor motions and attribute changes for every keypress or movement). If the terminal scrolls very slowly, set the 'scrolljump' to 5 or so. If the cursor is moved off the screen (e.g., with "j") Vim will scroll 5 lines at a time. Another possibility is to reduce the number of lines that Vim uses with the command "z{height}<CR>".

If the characters from the terminal are arriving with more than 1 second between them you might want to set the 'timeout' and/or 'ttimeout' option.

If you are using a color terminal that is slow when displaying lines beyond the end of a buffer, this is because Nvim is drawing the whitespace twice, in two sets of colours and attributes. To prevent this, use this command:

```
hi NonText cterm=NONE ctermfg=NONE
```

This draws the spaces with the default colours and attributes, which allows the second pass of drawing to be optimized away. **Note:** Although in theory the colours of whitespace are immaterial, in practice they change the colours of cursors and selections that cross them. This may have a visible, but minor, effect on some UIs.

Terminfo override

tui-termdefs

Below are the available fields in $NVIM_TERMDEFS. For keys of type `string[]`, the first entry is the unshifted variant of the key, and the second entry is the shifted variant.

```
Field                       Type
---------------------------------
RGB                         bool
Su                          bool
Tc                          bool
back_color_erase            bool

columns                     int
lines                       int
max_colors                  int

carriage_return             string
change_scroll_region        string
clear_screen                string
clr_eol                     string
clr_eos                     string
cursor_address              string
cursor_down                 string
cursor_home                 string
cursor_invisible            string
cursor_left                 string
cursor_normal               string
cursor_right                string
cursor_up                   string
delete_line                 string
enter_blink_mode            string
enter_bold_mode             string
enter_ca_mode               string
enter_dim_mode              string
enter_italics_mode          string
enter_reverse_mode          string
enter_secure_mode           string
enter_standout_mode         string
enter_underline_mode        string
erase_chars                 string
exit_attribute_mode         string
exit_ca_mode                string
from_status_line            string
insert_line                 string
keypad_local                string
keypad_xmit                 string
parm_delete_line            string
parm_down_cursor            string
parm_insert_line            string
parm_left_cursor            string
parm_right_cursor           string
parm_up_cursor              string
set_a_background            string
set_a_foreground            string
set_attributes              string
set_lr_margin               string
to_status_line              string

enter_strikethrough_mode    string
reset_cursor_color          string
reset_cursor_style          string
set_cursor_color            string
set_cursor_style            string
set_rgb_background          string
set_rgb_foreground          string
set_underline_style         string

key_backspace               string

Uganda copying copyright license

SUMMARY

Kuwasha

Vim is Charityware. You can use and copy it as much as you like, but you are encouraged to make a donation for needy children in Uganda. Please see kcc below or visit the Kuwasha web site, available at the following URL:

https://www.kuwasha.net

You can also sponsor the development of Vim. Vim sponsors can vote for features. See sponsor. The money goes to Uganda anyway.

iccf ICCF

ICCF Holland and Kuwasha

Bram Moolenaar's charity, ICCF Holland, has long supported the education of children in Uganda through the Kibaale Children's Centre. Following Bram's passing in 2023, ICCF Holland transferred all activities to its sister charity Kuwasha in Canada and dissolved at the end of 2025.

Donations from Vim users are still welcome and will continue to go directly to Uganda. To continue supporting this cause, please send contributions to Kuwasha.

License

The Open Publication License applies to the Vim documentation, see manual-copyright.

=== begin of license ===

VIM LICENSE

I) There are no restrictions on distributing unmodified copies of Vim except that they must include this license text. You can also distribute unmodified parts of Vim, likewise unrestricted except that they must include this license text. You are also allowed to include executables that you made from the unmodified Vim sources, plus your own usage examples and Vim scripts.

II) It is allowed to distribute a modified (or extended) version of Vim, including executables and/or source code, when the following four conditions are met:
1) This license text must be included unmodified.
2) The modified Vim must be distributed in one of the following five ways:
a) If you make changes to Vim yourself, you must clearly describe in the distribution how to contact you. When the maintainer asks you (in any way) for a copy of the modified Vim you distributed, you must make your changes, including source code, available to the maintainer without fee. The maintainer reserves the right to include your changes in the official version of Vim. What the maintainer will do with your changes and under what license they will be distributed is negotiable. If there has been no negotiation then this license, or a later version, also applies to your changes. The current maintainers are listed here:
https://github.com/orgs/vim/people
If this changes it will be announced in appropriate places (most likely vim.sf.net, www.vim.org and/or comp.editors). When it is completely impossible to contact the maintainer, the obligation to send him your changes ceases. Once the maintainer has confirmed that he has received your changes they will not have to be sent again.
b) If you have received a modified Vim that was distributed as mentioned under a) you are allowed to further distribute it unmodified, as mentioned at I). If you make additional changes the text under a) applies to those changes.
c) Provide all the changes, including source code, with every copy of the modified Vim you distribute. This may be done in the form of a context diff. You can choose what license to use for new code you add. The changes and their license must not restrict others from making their own changes to the official version of Vim.
d) When you have a modified Vim which includes changes as mentioned under c), you can distribute it without the source code for the changes if the following three conditions are met:

- The license that applies to the changes permits you to distribute

  the changes to the Vim maintainer without fee or restriction, and permits the Vim maintainer to include the changes in the official version of Vim without fee or restriction.
- You keep the changes for at least three years after last

  distributing the corresponding modified Vim. When the maintainer or someone who you distributed the modified Vim to asks you (in any way) for the changes within this period, you must make them available to him.
- You clearly describe in the distribution how to contact you. This

  contact information must remain valid for at least three years after last distributing the corresponding modified Vim, or as long

as possible.
e) When the GNU General Public License (GPL) applies to the changes, you can distribute the modified Vim under the GNU GPL version 2 or any later version.
3) A message must be added, at least in the output of the ":version" command and in the intro screen, such that the user of the modified Vim is able to see that it was modified. When distributing as mentioned under 2)e) adding the message is only required for as far as this does not conflict with the license used for the changes.
4) The contact information as required under 2)a) and 2)d) must not be removed or changed, except that the person himself can make corrections.

III) If you distribute a modified version of Vim, you are encouraged to use the Vim license for your changes and make them available to the maintainer, including the source code. The preferred way to do this is by e-mail or by uploading the files to a server and e-mailing the URL. If the number of changes is small (e.g., a modified Makefile) e-mailing a context diff will do. The e-mail address to be used is <maintainer@vim.org>

IV) It is not allowed to remove this license from the distribution of the Vim sources, parts of it or from a modified version. You may use this license for previous Vim releases instead of the license that they came with, at your option.

=== end of license ===

Note:

- If you are happy with Vim, please express that by reading the rest of this file and consider helping needy children in Uganda.
- If you want to support further Vim development consider becoming a sponsor. The money goes to Uganda anyway.
- According to Richard Stallman the Vim license is GNU GPL compatible. A few minor changes have been made since he checked it, but that should not make a difference.
- If you link Vim with a library that goes under the GNU GPL, this limits further distribution to the GNU GPL. Also when you didn't actually change anything in Vim.
- Once a change is included that goes under the GNU GPL, this forces all further changes to also be made under the GNU GPL or a compatible license.

Kibaale Children's Centre

kcc Kibaale charity

Kibaale Children's Centre (KCC) is located in Kibaale, a small town in the south of Uganda, near Tanzania, in East Africa. The area is known as Rakai District. The population is mostly farmers. Although people are poor, there usually is enough food. But this district is suffering from AIDS more than any other part of the world. Some say that it started there. Estimations are that in the past 10 to 30% of the Ugandans are infected with HIV. Because parents die, there are many orphans. In this district about 60,000 children have lost one or both parents, out of a population of 350,000. Although AIDS is now mostly under control, the problems are still continuing.

The children need a lot of help. The KCC is working hard to provide the needy with food, medical care and education. Food and medical care to keep them healthy now, and education so that they can take care of themselves in the future. KCC works on a Christian base, but help is given to children of any religion.

The key to solving the problems in this area is education. This has been neglected in the past years with president Idi Amin and the following civil wars. Now that the government is stable again, the children and parents have to learn how to take care of themselves and how to avoid infections. There is also help for people who are ill and hungry, but the primary goal is to prevent people from getting ill and to teach them how to grow healthy food.

Most of the orphans are living in an extended family. An uncle or older sister is taking care of them. Because these families are big and the income (if any) is low, a child is lucky if it gets healthy food. Clothes, medical care and schooling is beyond its reach. To help these needy children, a sponsorship program was put into place. A child can be financially adopted. For a few dollars a month KCC sees to it that the child gets indispensable items, is healthy, goes to school and KCC takes care of anything else that needs to be done for the child and the family that supports it.

Besides helping the child directly, the environment where the child grows up needs to be improved. KCC helps schools to improve their teaching methods. There is a demonstration school at the centre and teacher trainings are given. Health workers are being trained, hygiene education is carried out and households are stimulated to build a proper latrine. I helped setting up a production site for cement slabs. These are used to build a good latrine. They are sold below cost price.

There is a clinic at the project, which provides children and their family medical help. Since 2020 a maternity ward was added and 24/7 service is available. When needed, transport to a hospital is offered. Immunization programs are carried out and help is provided when an epidemic is breaking out (measles and cholera have been a problem).

Summer 1994 to summer 1995 Bram spent a whole year at the centre, working as a volunteer. Bram helped to expand the centre and worked in the area of water and sanitation. Bram learned that the help that the KCC provides really helps. When Bram came back to Holland, he wanted to continue supporting KCC. To do this he has been raising funds and organizing the sponsorship program.

How do you know that the money will be spent right? First of all you have the personal guarantee of Bram as the author of Vim, who knew the people working at the centre personally. Furthermore, the centre has been co-sponsored and inspected by World Vision, Save the Children Fund and is now under the supervision of Pacific Academy Outreach Society. Bram has visited the centre many times, starting in 1993. The visit reports are have been shared on the ICCF web site (may no longer be available).

If you have any further questions, send an e-mail: info@kuwasha.net.

The address of the centre is:

Kibaale Children's Centre
p.o. box 1658
Masaka, Uganda, East Africa

Undo and redo

The basics are explained in section 02.5 of the user manual.

1. Undo and redo commands undo-commands

<Undo> or undo <Undo> u
u Undo [count] changes. The cursor returns to its original position.

:u :un :undo
:u[ndo] Undo one change.

E830

:u[ndo] {N} Jump to after change number {N}. See undo-branches for the meaning of {N}.

:u[ndo]! Undo one change and remove it from undo history.

E5767

:u[ndo]! {N} Like ":u[ndo] {N}", but forget all changes in the current undo branch up until {N}. You may only use ":undo! {N}" to move backwards in the same undo branch, not to redo or switch to a different undo branch.

CTRL-R

CTRL-R Redo [count] changes which were undone.

:red :redo redo
:red[o] Redo one change which was undone.

U

U Undo all latest changes on one line, the line where the latest change was made. U itself also counts as a change, and thus U undoes a previous U.

The last changes are remembered. You can use the undo and redo commands above to revert the text to how it was before each change. You can also apply the changes again, getting back the text before the undo.

The "U" command is treated by undo/redo just like any other command. Thus a "u" command undoes a "U" command and a 'CTRL-R' command redoes it again. When mixing "U", "u" and 'CTRL-R' you will notice that the "U" command will restore the situation of a line to before the previous "U" command. This may be confusing. Try it out to get used to it.
The "U" command will always mark the buffer as changed. When "U" changes the buffer back to how it was without changes, it is still considered changed. Use "u" to undo changes until the buffer becomes unchanged.

2. Two ways of undo undo-two-ways

How undo and redo commands work depends on the 'u' flag in 'cpoptions'. There is the Vim way ('u' excluded) and the Vi-compatible way ('u' included). In the Vim way, "uu" undoes two changes. In the Vi-compatible way, "uu" does nothing (undoes an undo).

'u' excluded, the Vim way:
You can go back in time with the undo command. You can then go forward again with the redo command. If you make a new change after the undo command, the redo will not be possible anymore.

'u' included, the Vi-compatible way:
The undo command undoes the previous change, and also the previous undo command. The redo command repeats the previous undo command. It does NOT repeat a change command, use "." for that.

Examples	Vim way	Vi-compatible way
"uu"	two times undo	no-op
"u CTRL-R"	no-op	two times undo

Rationale: Nvi uses the "." command instead of CTRL-R. Unfortunately, this is not Vi compatible. For example "dwdwu." in Vi deletes two words, in Nvi it does nothing.

3. Undo blocks undo-blocks

One undo command normally undoes a typed command, no matter how many changes that command makes. This sequence of undo-able changes forms an undo block. Thus if the typed key(s) call a function, all the commands in the function are undone together.

If you want to write a function or script that doesn't create a new undoable change but joins in with the previous change use this command:

:undoj :undojoin E790
:undoj[oin] Join further changes with the previous undo block.
Warning: Use with care, it may prevent the user from properly undoing changes. Don't use this after undo or redo.

This is most useful when you need to prompt the user halfway through a change. For example in a function that calls getchar(). Do make sure that there was

a related change before this that you must join with.

This doesn't work by itself, because the next key press will start a new change again. But you can do something like this:

```
:undojoin | delete
```

After this a "u" command will undo the delete command and the previous change.

undo-break undo-close-block

To do the opposite, use a new undo block for the next change, in Insert mode use CTRL-G u. This is useful if you want an insert command to be undoable in parts. E.g., for each sentence. i_CTRL-G_u

Setting the value of 'undolevels' also closes the undo block. Even when the new value is equal to the old value. Use g:undolevels to explicitly read and write only the global value of 'undolevels'.

```
let &g:undolevels = &g:undolevels
```

Note that the similar-looking assignment let &undolevels=&undolevels does not preserve the global option value of 'undolevels' in the event that the local option has been set to a different value. For example:

```
" Start with different global and local values for 'undolevels'.
let &g:undolevels = 1000
let &l:undolevels = 2000
" This assignment changes the global option to 2000:
let &undolevels = &undolevels
```

4. Undo branches

undo-branches undo-tree

Above we only discussed one line of undo/redo. But it is also possible to branch off. This happens when you undo a few changes and then make a new change. The undone changes become a branch. You can go to that branch with the following commands. The undo-tree of a file can be visualized and interactively applied using :Undotree.

This is explained in the user manual: usr_32.txt.

:undol :undolist

:undol[ist] List the leafs in the tree of changes. Example:

```
number changes  when               saved
       88      88  2010/01/04 14:25:53
      108     107  08/07 12:47:51
      136      46  13:33:01             7
      166     164  3 seconds ago
```

The "number" column is the change number. This number continuously increases and can be used to identify a specific undo-able change, see :undo.
The "changes" column is the number of changes to this leaf from the root of the tree.
The "when" column is the date and time when this change was made. The four possible formats are:

```
    N seconds ago
    HH:MM:SS             hour, minute, seconds
    MM/DD HH:MM:SS       idem, with month and day
    YYYY/MM/DD HH:MM:SS  idem, with year
```

The "saved" column specifies, if this change was written to disk and which file write it was. This can be used with the :later and :earlier commands.
For more details use the undotree() function.

g-

g- Go to older text state. With a count repeat that many times.

:ea :earlier

:ea[rlier] {count} Go to older text state {count} times.
:ea[rlier] {N}s Go to older text state about {N} seconds before.
:ea[rlier] {N}m Go to older text state about {N} minutes before.
:ea[rlier] {N}h Go to older text state about {N} hours before.
:ea[rlier] {N}d Go to older text state about {N} days before.

:ea[rlier] {N}f Go to older text state {N} file writes before.
When changes were made since the last write ":earlier 1f" will revert the text to the state when it was written. Otherwise it will go to the write before that.
When at the state of the first file write, or when the file was not written, ":earlier 1f" will go to before the first change.

g+

g+ Go to newer text state. With a count repeat that many times.

:lat :later

:lat[er] {count} Go to newer text state {count} times.

:lat[er] {N}s		Go to newer text state about {N} seconds later.
:lat[er] {N}m		Go to newer text state about {N} minutes later.
:lat[er] {N}h		Go to newer text state about {N} hours later.
:lat[er] {N}d		Go to newer text state about {N} days later.

:lat[er] {N}f		Go to newer text state {N} file writes later.
			When at the state of the last file write, ":later 1f"
			will go to the newest text state.

Note that text states will become unreachable when undo information is cleared for 'undolevels'.

Don't be surprised when moving through time shows multiple changes to take place at a time. This happens when moving through the undo tree and then making a new change.

EXAMPLE

Start with this text:
one two three

Delete the first word by pressing "x" three times:
ne two three
e two three
two three

Now undo that by pressing "u" three times:
e two three
ne two three
one two three

Delete the second word by pressing "x" three times:
one wo three
one o three
one three

Now undo that by using "g-" three times:
one o three
one wo three
two three

You are now back in the first undo branch, after deleting "one". Repeating "g-" will now bring you back to the original text:
e two three
ne two three
one two three

Jump to the last change with ":later 1h":
one three

And back to the start again with ":earlier 1h":
one two three

Note that using "u" and CTRL-R will not get you to all possible text states while repeating "g-" and "g+" does.

5. Undo persistence

undo-persistence persistent-undo

When unloading a buffer Vim normally destroys the tree of undos created for that buffer. By setting the 'undofile' option, Vim will automatically save your undo history when you write a file and restore undo history when you edit the file again.

The 'undofile' option is checked after writing a file, before the BufWritePost autocommands. If you want to control what files to write undo information for, you can use a BufWritePre autocommand:

```
au BufWritePre /tmp/* setlocal noundofile
```

Vim saves undo trees in a separate undo file, one for each edited file, using a simple scheme that maps filesystem paths directly to undo files. Vim will detect if an undo file is no longer synchronized with the file it was written for (with a hash of the file contents) and ignore it when the file was changed after the undo file was written, to prevent corruption. An undo file is also ignored if its owner differs from the owner of the edited file, except when the owner of the undo file is the current user. Set 'verbose' to get a message about that when opening a file.

Location of the undo files is controlled by the 'undodir' option, by default they are saved to the dedicated directory in the application data folder.

You can also save and restore undo histories by using ":wundo" and ":rundo" respectively:

:wu :wundo
:wu[ndo][!] {file}
		Write undo history to {file}.
		When {file} exists and it does not look like an undo file
		(the magic number at the start of the file is wrong), then
		this fails, unless the ! was added.
		If it exists and does look like an undo file it is
		overwritten. If there is no undo-history, nothing will be
		written.
		Implementation detail: Overwriting happens by first deleting
		the existing file and then creating a new file with the same
		name. So it is not possible to overwrite an existing undofile
		in a write-protected directory.

:rund :rundo

:rund[o] {file} Read undo history from {file}.

You can use these in autocommands to explicitly specify the name of the history file. E.g.:

```
au BufReadPost * call ReadUndo()
au BufWritePost * call WriteUndo()
func ReadUndo()
  if filereadable(expand('%:h') .. '/UNDO/' .. expand('%:t'))
    rundo %:h/UNDO/%:t
  endif
endfunc
func WriteUndo()
  let dirname = expand('%:h') .. '/UNDO'
  if !isdirectory(dirname)
    call mkdir(dirname)
  endif
  wundo %:h/UNDO/%:t
endfunc
```

You should keep 'undofile' off, otherwise you end up with two undo files for every write.

You can use the undofile() function to find out the file name that Vim would use.

Note that while reading/writing files and 'undofile' is set most errors will be silent, unless 'verbose' is set. With :wundo and :rundo you will get more error messages, e.g., when the file cannot be read or written.

NOTE: undo files are never deleted by Vim. You need to delete them yourself.

Reading an existing undo file may fail for several reasons:
E822 It cannot be opened, because the file permissions don't allow it.
E823 The magic number at the start of the file doesn't match. This usually means it is not an undo file.
E824 The version number of the undo file indicates that it's written by a newer version of Vim. You need that newer version to open it. Don't write the buffer if you want to keep the undo info in the file.
"File contents changed, cannot use undo info"
The file text differs from when the undo file was written. This means the undo file cannot be used, it would corrupt the text. This also happens when 'encoding' differs from when the undo file was written.
E825 The undo file does not contain valid contents and cannot be used.
"Not reading undo file, owner differs"
The undo file is owned by someone else than the owner of the text file. For safety the undo file is not used.

Writing an undo file may fail for these reasons:
E828 The file to be written cannot be created. Perhaps you do not have write permissions in the directory.
"Cannot write undo file in any directory in 'undodir'"
None of the directories in 'undodir' can be used.
"Will not overwrite with undo file, cannot read"
A file exists with the name of the undo file to be written, but it cannot be read. You may want to delete this file or rename it.
"Will not overwrite, this is not an undo file"
A file exists with the name of the undo file to be written, but it does not start with the right magic number. You may want to delete this file or rename it.
"Skipping undo file write, nothing to undo"
There is no undo information to be written, nothing has been changed or 'undolevels' is negative.
E829 An error occurred while writing the undo file. You may want to try again.

6. Remarks about undo undo-remarks

The number of changes that are remembered is set with the 'undolevels' option. If it is zero, the Vi-compatible way is always used. If it is negative no undo is possible. Use this if you are running out of memory.

clear-undo

When you set 'undolevels' to -1 the undo information is not immediately cleared, this happens at the next change. To force clearing the undo information you can use these commands:

```
:let old_undolevels = &l:undolevels
:setlocal undolevels=-1
:exe "normal a \<BS>\<Esc>"
:let &l:undolevels = old_undolevels
:unlet old_undolevels
```

Note use of &l:undolevels to explicitly read the local value of 'undolevels' and the use of :setlocal to change only the local option (which takes precedence over the corresponding global option value). Saving the option value via the use of &undolevels is unpredictable; it reads either the local value (if one has been set) or the global value (otherwise). Also, if a local value has been set, changing the option via :set undolevels will change both

the global and local values, requiring extra work to save and restore both values.

Marks for the buffer ('a to 'z) are also saved and restored, together with the text.

When all changes have been undone, the buffer is not considered to be changed. It is then possible to exit Vim with ":q" instead of ":q!".
Note that this is relative to the last write of the file. Typing "u" after ":w" actually changes the buffer, compared to what was written, so the buffer is considered changed then.

When manual folding is being used, the folds are not saved and restored. Only changes completely within a fold will keep the fold as it was, because the first and last line of the fold don't change.

The numbered registers can also be used for undoing deletes. Each time you delete text, it is put into register "1. The contents of register "1 are shifted to "2, etc. The contents of register "9 are lost. You can now get back the most recent deleted text with the put command: '"1P'. (also, if the deleted text was the result of the last delete or copy operation, 'P' or 'p' also works as this puts the contents of the unnamed register). You can get back the text of three deletes ago with '"3P'.

redo-register

If you want to get back more than one part of deleted text, you can use a special feature of the repeat command ".". It will increase the number of the register used. So if you first do '"1P', the following "." will result in a '"2P'. Repeating this will result in all numbered registers being inserted.

Example:	If you deleted text with 'dd....' it can be restored with
		'"1P....'.

If you don't know in which register the deleted text is, you can use the :display command. An alternative is to try the first register with '"1P', and if it is not what you want do 'u.'. This will remove the contents of the first put, and repeat the put command for the second register. Repeat the 'u.' until you got what you want.

Defining and using functions.

This is introduced in section 41.7 of the user manual.

1. Defining a function ~

New functions can be defined. These can be called just like builtin functions. The function executes a sequence of Ex commands. Normal mode commands can be executed with the :normal command.

The function name must start with an uppercase letter, to avoid confusion with builtin functions. To prevent from using the same name in different scripts make them script-local. If you do use a global function then avoid obvious, short names. A good habit is to start the function name with the name of the script, e.g., "HTMLcolor()".

It is also possible to use curly braces, see curly-braces-names.

The autoload facility is useful to define a function only when it's called.

local-function

A function local to a script must start with "s:". A local script function can only be called from within the script and from functions, user commands and autocommands defined in the script. It is also possible to call the function from a mapping defined in the script, but then <SID> must be used instead of "s:" when the mapping is expanded outside of the script.
There are only script-local functions, no buffer-local or window-local functions.

:fu :function E128 E129 E123 E454 E1058 E1068

:fu[nction] List all functions and their arguments.

:fu[nction][!] {name} List function {name}, annotated with line numbers unless "!" is given.
{name} may be a Dictionary Funcref entry:

```
:function dict.init
```

Note that {name} is not an expression, you cannot use a variable that is a function reference. You can use this dirty trick to list the function referred to with variable "Funcref":

```
let g:MyFuncref = Funcref
func g:MyFuncref
unlet g:MyFuncref
```

:fu[nction] /{pattern} List functions with a name matching {pattern}.
Example that lists all functions ending with "File":

```
:function /File$
```

:function-verbose

When 'verbose' is non-zero, listing a function will also display where it was last defined. Example:

```
:verbose function SetFileTypeSH
    function SetFileTypeSH(name)
        Last set from /usr/share/vim/vim-7.0/filetype.vim
```

See :verbose-cmd for more information.

E124 E125 E853 E884

:fu[nction][!] {name}([arguments]) [range] [abort] [dict] [closure]
Define a new function by the name {name}. The body of the function follows in the next lines, until the matching :endfunction.

The name must be made of alphanumeric characters and '_' and must start with a capital or "s:" (see above). Note that using "b:", "l:", etc. is not allowed (since patch 7.4.260 E884 is given if the function name has a colon, e.g. for "foo:bar()"), while a leading "g:" is skipped and still requires a following capital letter.

{name} may be a Dictionary Funcref entry:

```
:function dict.init(arg)
```

"dict" must be an existing dictionary. The entry "init" is added if it didn't exist yet. Otherwise [!] is required to overwrite an existing function. The result is a Funcref to a numbered function. The function can only be used with a Funcref and will be deleted if there are no more references to it.

E127 E122

When a function by this name already exists and [!] is not used an error message is given. There is one exception: When sourcing a script again, a function that was previously defined in that script will be silently replaced.
When [!] is used, an existing function is silently

replaced. Unless it is currently being executed, that is an error.
NOTE: Use ! wisely. If used without care it can cause an existing function to be replaced unexpectedly, which is hard to debug.

For the {arguments} see function-argument.

:func-range a:firstline a:lastline
When the [range] argument is added, the function is expected to take care of a range itself. The range is passed as "a:firstline" and "a:lastline". If [range] is excluded, ":{range}call" will call the function for each line in the range, with the cursor on the start of each line. See function-range-example.
The cursor is still moved to the first line of the range, as is the case with all Ex commands.

:func-abort
When the [abort] argument is added, the function will abort as soon as an error is detected.

:func-dict
When the [dict] argument is added, the function must be invoked through an entry in a Dictionary. The local variable "self" will then be set to the dictionary. See Dictionary-function.

:func-closure E932
When the [closure] argument is added, the function can access variables and arguments from the outer scope. This is usually called a closure. In this example Bar() uses "x" from the scope of Foo(). It remains referenced even after Foo() returns:

```
:function! Foo()
:  let x = 0
:  function! Bar() closure
:    let x += 1
:    return x
:  endfunction
:  return funcref('Bar')
:endfunction

:let F = Foo()
:echo F()
```

```
1
```

```
:echo F()
```

```
2
```

```
:echo F()
```

```
3
```

function-search-undo
The last used search pattern and the redo command "." will not be changed by the function. This also implies that the effect of :nohlsearch is undone when the function returns.

:endf :endfunction E126 E193 W22
:endf[unction] [argument]
The end of a function definition. Best is to put it on a line by its own, without [argument].

[argument] can be:
```
        | command       command to execute next
        \n command      command to execute next
        " comment       always ignored
        anything else   ignored, warning given when
                        'verbose' is non-zero
```
The support for a following command was added in Vim 8.0.0654, before that any argument was silently ignored.

To be able to define a function inside an :execute command, use line breaks instead of :bar:

```
:exe "func Foo()\necho 'foo'\nendfunc"
```

:delf :delfunction E130 E131 E933
:delf[unction][!] {name}
Delete function {name}.
{name} can also be a Dictionary entry that is a Funcref:

```
:delfunc dict.init
```

This will remove the "init" entry from "dict". The function is deleted if there are no more references to

it.
With the ! there is no error if the function does not exist.

:retu :return E133

:retu[rn] [expr] Return from a function. When [expr] is given, it is evaluated and returned as the result of the function. If [expr] is not given, the number 0 is returned. When a function ends without an explicit ":return", the number 0 is returned.
Note that there is no check for unreachable lines, thus there is no warning if commands follow ":return".
Also, there is no check if the following line contains a valid command. Forgetting the line continuation backslash may go unnoticed:

```
return 'some text'
       .. ' some more text'
```

Will happily return "some text" without an error. It should have been:

```
return 'some text'
       \ .. ' some more text'
```

If the ":return" is used after a :try but before the matching :finally (if present), the commands following the ":finally" up to the matching :endtry are executed first. This process applies to all nested ":try"s inside the function. The function returns at the outermost ":endtry".

function-argument a:var

An argument can be defined by giving its name. In the function this can then be used as "a:name" ("a:" for argument).

a:0 a:1 a:000 E740 ...

Up to 20 arguments can be given, separated by commas. After the named arguments an argument "..." can be specified, which means that more arguments may optionally be following. In the function the extra arguments can be used as "a:1", "a:2", etc. "a:0" is set to the number of extra arguments (which can be 0). "a:000" is set to a List that contains these arguments. Note that "a:1" is the same as "a:000[0]".

E742

The a: scope and the variables in it cannot be changed, they are fixed. However, if a composite type is used, such as List or Dictionary , you can change their contents. Thus you can pass a List to a function and have the function add an item to it. If you want to make sure the function cannot change a List or Dictionary use :lockvar.

It is also possible to define a function without any arguments. You must still supply the () then.

It is allowed to define another function inside a function body.

optional-function-argument

You can provide default values for positional named arguments. This makes them optional for function calls. When a positional argument is not specified at a call, the default expression is used to initialize it. This only works for functions declared with :function, not for lambda expressions expr-lambda.

Example:

```
function Something(key, value = 10)
   echo a:key .. ": " .. a:value
endfunction
call Something('empty') "empty: 10"
call Something('key', 20)       "key: 20"
```

The argument default expressions are evaluated at the time of the function call, not when the function is defined. Thus it is possible to use an expression which is invalid the moment the function is defined. The expressions are also only evaluated when arguments are not specified during a call.

E989

Optional arguments with default expressions must occur after any mandatory arguments. You can use "..." after all optional named arguments.

It is possible for later argument defaults to refer to prior arguments, but not the other way around. They must be prefixed with "a:", as with all arguments.

Example that works:

```
:function Okay(mandatory, optional = a:mandatory)
:endfunction
```

Example that does NOT work:

```
:function NoGood(first = a:second, second = 10)
:endfunction
```

When not using "...", the number of arguments in a function call must be at least equal to the number of mandatory named arguments. When using "...", the number of arguments may be larger than the total of mandatory and optional arguments.

local-variables

Inside a function local variables can be used. These will disappear when the function returns. Global variables need to be accessed with "g:". Inside functions local variables are accessed without prepending anything. But you can also prepend "l:" if you like. This is required for some reserved names, such as "version".

Example:

```
:function Table(title, ...)
:  echohl Title
:  echo a:title
:  echohl None
:  echo a:0 .. " items:"
:  for s in a:000
:    echon ' ' .. s
:  endfor
:endfunction
```

This function can then be called with:

```
call Table("Table", "line1", "line2")
call Table("Empty Table")
```

To return more than one value, return a List:

```
:function Compute(n1, n2)
:  if a:n2 == 0
:    return ["fail", 0]
:  endif
:  return ["ok", a:n1 / a:n2]
:endfunction
```

This function can then be called with:

```
:let [success, div] = Compute(102, 6)
:if success == "ok"
:  echo div
:endif
```

1. Calling a function ~

:cal :call E107 E117

:[range]cal[l] {name}([arguments])
Call a function. The name of the function and its arguments are as specified with :function. Up to 20 arguments can be used. The returned value is discarded.
Without a range and for functions that accept a range, the function is called once. When a range is given the cursor is positioned at the start of the first line before executing the function.
When a range is given and the function doesn't handle it itself, the function is executed for each line in the range, with the cursor in the first column of that line. The cursor is left at the last line (possibly moved by the last function call). The arguments are re-evaluated for each line. Thus this works:

function-range-example

```
:function Mynumber(arg)
:  echo line(".") .. " " .. a:arg
:endfunction
:1,5call Mynumber(getline("."))
```

The "a:firstline" and "a:lastline" are defined anyway, they can be used to do something different at the start or end of the range.

Example of a function that handles the range itself:

```
:function Cont() range
:  execute (a:firstline + 1) .. "," .. a:lastline .. 's/^/\t\\ '
:endfunction
:4,8call Cont()
```

This function inserts the continuation character "\" in front of all the lines in the range, except the first one.

When the function returns a composite value it can be further
dereferenced, but the range will not be used then. Example:

```
:4,8call GetDict().method()
```

Here GetDict() gets the range but method() does not.

E132

The recursiveness of user functions is restricted with the 'maxfuncdepth'
option.

It is also possible to use :eval. It does not support a range, but does
allow for method chaining, e.g.:

```
eval GetList()->Filter()->append('$')
```

A function can also be called as part of evaluating an expression or when it
is used as a method:

```
let x = GetList()
let y = GetList()->Filter()
```

1. Cleaning up in a function ~

:defe :defer
:defe[r] {func}({args}) Call {func} when the current function is done.
{args} are evaluated here.

Quite often a command in a function has a global effect, which must be undone
when the function finishes. Handling this in all kinds of situations can be a
hassle. Especially when an unexpected error is encountered. This can be done
with try / finally blocks, but this gets complicated when there is more
than one.

A much simpler solution is using defer. It schedules a function call when
the function is returning, no matter if there is an error. Example:

```
func Filter(text) abort
  call writefile(a:text, 'Tempfile')
  call system('filter < Tempfile > Outfile')
  call Handle('Outfile')
  call delete('Tempfile')
  call delete('Outfile')
endfunc
```

Here 'Tempfile' and 'Outfile' will not be deleted if something causes the
function to abort. :defer can be used to avoid that:

```
func Filter(text) abort
  call writefile(a:text, 'Tempfile')
  defer delete('Tempfile')
  defer delete('Outfile')
  call system('filter < Tempfile > Outfile')
  call Handle('Outfile')
endfunc
```

Note that deleting "Outfile" is scheduled before calling system(), since it
can be created even when system() fails.

The deferred functions are called in reverse order, the last one added is
executed first. A useless example:

```
func Useless() abort
  for s in range(3)
    defer execute('echomsg "number ' .. s .. '"')
  endfor
endfunc
```

Now :messages shows:
        number 2
        number 1
        number 0

Any return value of the deferred function is discarded. The function cannot
be followed by anything, such as "->func" or ".member". Currently
:defer GetArg()->TheFunc() does not work, it may work in a later version.

Errors are reported but do not cause aborting execution of deferred functions
or altering execution outside of deferred functions.

No range is accepted. The function can be a partial with extra arguments, but
not with a dictionary. E1300

1. Automatically loading functions ~

autoload-functions

When using many or large functions, it's possible to automatically define them

only when they are used. There are two methods: with an autocommand and with the "autoload" directory in 'runtimepath'.

Using an autocommand

This is introduced in the user manual, section 41.14.

The autocommand is useful if you have a plugin that is a long Vim script file. You can define the autocommand and quickly quit the script with :finish. That makes Vim startup faster. The autocommand should then load the same file again, setting a variable to skip the :finish command.

Use the FuncUndefined autocommand event with a pattern that matches the function(s) to be defined. Example:

```
:au FuncUndefined BufNet* source ~/vim/bufnetfuncs.vim
```

The file "~/vim/bufnetfuncs.vim" should then define functions that start with "BufNet". Also see FuncUndefined.

Using an autoload script

autoload E746

This is introduced in the user manual, section 41.15.

Using a script in the "autoload" directory is simpler, but requires using exactly the right file name. A function that can be autoloaded has a name like this:

```
:call filename#funcname()
```

When such a function is called, and it is not defined yet, Vim will search the "autoload" directories in 'runtimepath' for a script file called "filename.vim". For example "~/.config/nvim/autoload/filename.vim". That file should then define the function like this:

```
function filename#funcname()
   echo "Done!"
endfunction
```

If the file doesn't exist, Vim will also search in 'packpath' (under "start") to allow calling packages' functions from your vimrc when the packages have not been added to 'runtimepath' yet (see packages).

The file name and the name used before the # in the function must match exactly, and the defined function must have the name exactly as it will be called.

It is possible to use subdirectories. Every # in the function name works like a path separator. Thus when calling a function:

```
:call foo#bar#func()
```

Vim will look for the file "autoload/foo/bar.vim" in 'runtimepath'.

This also works when reading a variable that has not been set yet:

```
:let l = foo#bar#lvar
```

However, when the autoload script was already loaded it won't be loaded again for an unknown variable.

When assigning a value to such a variable nothing special happens. This can be used to pass settings to the autoload script before it's loaded:

```
:let foo#bar#toggle = 1
:call foo#bar#func()
```

Note that when you make a mistake and call a function that is supposed to be defined in an autoload script, but the script doesn't actually define the function, you will get an error message for the missing function. If you fix the autoload script it won't be automatically loaded again. Either restart Vim or manually source the script.

Also note that if you have two script files, and one calls a function in the other and vice versa, before the used function is defined, it won't work. Avoid using the autoload functionality at the toplevel.

Hint: If you distribute a bunch of scripts read distribute-script.

1. Various commands

various-cmds

CTRL-C

CTRL-C Interrupt the current command, script, mapping, prompt, or search.

In Normal mode, any pending command is aborted. During a search, interrupts the search.

Lua code cannot be interrupted unless it "yields" via vim.wait().

CTRL-L

CTRL-L Clears and redraws the screen. The redraw may happen later, after processing typeahead.
See also nvim__redraw().

CTRL-L-default

By default, also clears search highlighting :nohlsearch, removes multicursors, and updates diffs :diffupdate. default-mappings

:mod :mode E359

:mod[e] Clears and redraws the screen.
See also nvim__redraw().

:redr :redraw

:redr[aw][!] Redraws pending screen updates now, or the entire screen if "!" is included. To CLEAR the screen use :mode or CTRL-L.
It can be used to redraw the screen in a script or function (or a mapping if 'lazyredraw' is set).
See also nvim__redraw().

:redraws :redrawstatus

:redraws[tatus][!] Redraws the status line and window bar of the current window, or all status lines and window bars if "!" is included. Redraws the commandline instead if it contains the 'ruler'. Useful if 'statusline' or 'winbar' includes an item that doesn't cause automatic updating.
See also nvim__redraw().

:redrawt :redrawtabline

:redrawt[abline] Redraw the tabline. Useful to update the tabline when 'tabline' includes an item that doesn't trigger automatic updating. See also nvim__redraw().

N<Del>

<Del> When entering a number: Remove the last digit.
Note: if you like to use <BS> for this, add this mapping to your vimrc:

```
:map CTRL-V <BS>   CTRL-V <Del>
```

ga :as :ascii

:as[cii] or
ga Print the ascii value of the character under the cursor in decimal, hexadecimal and octal.
Mnemonic: Get Ascii value.

For example, when the cursor is on a 'R':

<R> 82, Hex 52, Octal 122

When the character is a non-standard ASCII character, the non-printable version is also given.

When the character is larger than 127:

<<81>> 129, Hex 0081, Octal 201
<p> 254, Hex 00fe, Octal 376
(where <p> is a special character)

The <Nul> character in a file is stored internally as <NL>, but it will be shown as:

<^@> 0, Hex 00, Octal 000

If the character has composing characters these are also shown. The value of 'maxcombine' doesn't matter.

If the character can be inserted as a digraph, also output the two characters that can be used to create the character:

<ö> 246, Hex 00f6, Oct 366, Digr o:
This shows you can type CTRL-K o : to insert ö.

g8

g8 Print the hex values of the bytes used in the character under the cursor, assuming it is in UTF-8 encoding. This also shows composing characters. The value of 'maxcombine' doesn't matter.
Example of a character with two composing characters:

e0 b8 81 + e0 b8 b9 + e0 b9 89

8g8

8g8 Find an illegal UTF-8 byte sequence at or after the cursor.
Can be used when editing a file that was supposed to be UTF-8 but was read as if it is an 8-bit encoding because it contains illegal bytes.
Does not wrap around the end of the file.
Note that when the cursor is on an illegal byte or the cursor is halfway through a multibyte character the command won't move the cursor.

gx

gx Opens the current filepath, URL (decided by <cfile>, 'isfname'), or LSP "documentLink" at cursor using the system default handler.

In help files, gx treats help tags as https://neovim.io/doc/user/ URLs.

Mapped to vim.ui.open().

v_gx

{Visual}gx Opens the selected text using the system default handler. Mapped to vim.ui.open().

:p :pr :print E749

:[range]p[rint] [flags]
Print [range] lines (default current line). Can also be spelled :[range]| due to Vi compatibility (see :bar). Gives an error in an empty buffer.
In the GUI you can use the File.Print menu entry.
See ex-flags for [flags].
The :filter command can be used to only show lines matching a pattern.

:[range]p[rint] {count} [flags]
Print {count} lines, starting with [range] (default current line cmdline-ranges).
See ex-flags for [flags].

:l :list

:[range]l[ist] [count] [flags]
Same as :print, but show tabs as ">", trailing spaces as "-", and non-breakable space characters as "+" by default. Further changed by the 'listchars' option.
See ex-flags for [flags].

:nu :number

:[range]nu[mber] [count] [flags]
Same as :print, but precede each line with its line number. (See also hl-LineNr and 'numberwidth').
See ex-flags for [flags].

:#

:[range]# [count] [flags]
synonym for :number.

:#! vim-shebang

:#!{anything} Ignored, so that you can start a Vim script with:

```
#!vim -S
let mylogbook='$HOME/logbook.md'
exe $':e {mylogbook}'
$
put ='## ' .. strftime('%d. %b %Y')
norm! o
```

Make that script executable and run it to create a new diary entry.

:z E144

:[range]z[+-^.=][count] Display several lines of text surrounding the line specified with [range], or around the current line if there is no [range].

If there is a [count], that's how many lines you'll see; if there is no [count] and only one window then twice the value of the 'scroll' option is used, otherwise the current window height minus 3 is used.
This is the value of "scr" in the table below.

If there is a [count] the 'window' option is set to its value.

:z can be used either alone or followed by any of several marks. These have the following effect:

mark	first line	last line	new cursor line
+	current line	1 scr forward	1 scr forward
-	1 scr back	current line	current line
^	2 scr back	1 scr back	1 scr back
.	1/2 scr back	1/2 scr fwd	1/2 scr fwd
=	1/2 scr back	1/2 scr fwd	current line

Specifying no mark at all is the same as "+".
If the mark is "=", a line of dashes is printed
around the current line.

If the 'number' option is set, absolute line numbers
will be included in the output.

:z!

:[range]z![+-^.=][count]
Like ":z", but when [count] is not specified, it
defaults to the Vim window height minus one.

:[range]z[!]#[+-^.=][count] :z#

Like ":z" or ":z!", but number the lines.

:=

:= [args] Without [args]: prints the last line number.
With [args]: equivalent to :lua ={expr}. see :lua

:{range}= Prints the last line number in {range}. For example,
this prints the current line number:

```
:.=
```

:norm[al][!] {commands} :norm :normal
Execute Normal mode commands {commands}. This makes
it possible to execute Normal mode commands typed on
the command-line. {commands} are executed like they
are typed. For undo all commands are undone together.
Execution stops when an error is encountered.

If the [!] is given, mappings will not be used.
Without it, when this command is called from a
non-remappable mapping (:noremap), the argument can
be mapped anyway.

{commands} should be a complete command. If
{commands} does not finish a command, the last one
will be aborted as if <Esc> or <C-C> was typed.
This implies that an insert command must be completed
(to start Insert mode, see :startinsert). A ":"
command must be completed as well. And you can't
start Ex-mode.

The display is not updated while ":normal" is busy.

{commands} cannot start with a space. Put a count of
1 (one) before it, "1 " is one space.

This command cannot be followed by another command,
since any '|' is considered part of the command.

This command can be used recursively, but the depth is
limited by 'maxmapdepth'.

An alternative is to use :execute, which uses an
expression as argument. This allows the use of
printable characters to represent special characters.

Example:

```
:exe "normal \<c-w>\<c-w>"
```

:{range}norm[al][!] {commands} :normal-range

Execute Normal mode commands {commands} for each line
in the {range}. Before executing the {commands}, the
cursor is positioned in the first column of the range,
for each line. Otherwise it's the same as the
":normal" command without a range.

:sh :shell E371 E360
:sh[ell] Removed. vim-differences

:terminal :te
:te[rminal][!] [cmd] Run [cmd] in a non-interactive 'shell' in a new
terminal-emulator buffer. Without [cmd], start an
interactive 'shell'.

By default the current window is used. To open in
a split window, use :horizontal or :vertical:

```
:hor te
:vert te
```

Type i to enter Terminal-mode, then keys are sent to
the job running in the terminal. Type <C-\><C-N> to
leave Terminal-mode. CTRL-_CTRL-N. Type <C-\><C-O>
to execute a single normal mode command t_CTRL-_CTRL-O

Fails if changes have been made to the current buffer,
unless 'hidden' is set.

If [cmd] is omitted, and the 'shell' job exits with no
error, the buffer is closed automatically
default-autocmds.

To enter Terminal-mode automatically:

```
autocmd TermOpen * startinsert
```

:!cmd :!

:!{cmd} Execute {cmd} with 'shell'. See also :terminal.
For the filter command, see :range!.

The command runs in a non-interactive shell connected to a pipe (not a terminal). Use :terminal to run an interactive shell connected to a terminal.

Backgrounded ("&") commands must not write to stdout or stderr, the streams are closed immediately. E5677
Use jobstart() instead.

```
:call jobstart('foo', {'detach':1})
```

For powershell, chaining a stringed executable path requires using the call operator (&).

```
:!Write-Output "1`n2" | & "C:\Windows\System32\sort.exe" /r
```

Vim builds command line using options 'shell', 'shcf', 'sxq' and 'shq' in the following order:
&sh &shcf &sxq &shq {cmd} &shq &sxq
So setting both 'sxq' and 'shq' is possible but rarely useful. Additional escaping inside {cmd} may also be due to 'sxe' option.

Also, all cmdline-special characters in {cmd} are replaced by Vim before passing them to shell.

E34

Any "!" in {cmd} is replaced with the previous external command (see also 'cpoptions'), unless escaped by a backslash. Example: ":!ls" followed by ":!echo ! \! \\!" executes "echo ls ! \!".

Any "|" in {cmd} is passed to the shell, you cannot use it to append a Vim command. See :bar.

Any "%" in {cmd} is expanded to the current file name.
Any "#" in {cmd} is expanded to the alternate file name.
Special characters are not escaped, use quotes or shellescape():

```
:!ls "%"
:exe "!ls " .. shellescape(expand("%"),1)
```

Newline character ends {cmd} unless a backslash precedes the newline. What follows is interpreted as another : command.

After the command has been executed, the timestamp and size of the current file is checked timestamp.

If the command produces too much output some lines may be skipped so the command can execute quickly. No data is lost, this only affects the display. The last few lines are always displayed (never skipped).

To avoid the hit-enter prompt use:

```
:silent !{cmd}
```

:!!

:!! Repeat last ":!{cmd}".

:ve :ver :version

:ve[rsion] Print editor version and build information.
See also feature-compile.

:redi :redir

:redi[r][!] > {file} Redirect messages to file {file}. The messages which are the output of commands are written to that file, until redirection ends. The messages are also still shown on the screen. When [!] is included, an existing file is overwritten. When [!] is omitted, and {file} exists, this command fails.

Only one ":redir" can be active at a time. Calls to ":redir" will close any active redirection before starting redirection to the new target. For recursive use check out execute().

To stop the messages and commands from being echoed to the screen, put the commands in a function and call it with ":silent call Function()".
Alternatives are the 'verbosefile' option or execute() function, these can be used in combination with ":redir".

:redi[r] >> {file} Redirect messages to file {file}. Append if {file} already exists.

:redi[r] @{a-zA-Z}
:redi[r] @{a-zA-Z}> Redirect messages to register {a-z}. Append to the
                     contents of the register if its name is given
                     uppercase {A-Z}. The ">" after the register name is
                     optional.
:redi[r] @{a-z}>>   Append messages to register {a-z}.

:redi[r] @*>
:redi[r] @+>   Redirect messages to the selection or clipboard. For
                     backward compatibility, the ">" after the register
                     name can be omitted. See quotestar and quoteplus.
:redi[r] @*>>
:redi[r] @+>>   Append messages to the selection or clipboard.

:redi[r] @">   Redirect messages to the unnamed register. For
                     backward compatibility, the ">" after the register
                     name can be omitted.
:redi[r] @">>   Append messages to the unnamed register.

:redi[r] => {var}   Redirect messages to a variable. If the variable
                     doesn't exist, then it is created. If the variable
                     exists, then it is initialized to an empty string.
                     The variable will remain empty until redirection ends.
                     Only string variables can be used. After the
                     redirection starts, if the variable is removed or
                     locked or the variable type is changed, then further
                     command output messages will cause errors. When using
                     a local variable (l:var in a function or s:var in a
                     script) and another :redir causes the current one to
                     end, the scope might be different and the assignment
                     fails.
                     To get the output of one command the execute()
                     function can be used instead of redirection.

:redi[r] =>> {var}   Append messages to an existing variable. Only string
                     variables can be used.

:redi[r] END   End redirecting messages.

                                                  :filt :filter
:filt[er][!] {pattern} {command}
:filt[er][!] /{pattern}/ {command}
                     Restrict the output of {command} to lines matching
                     with {pattern}. For example, to list only xml files:

```
:filter /\.xml$/ oldfiles
```

                     If the [!] is given, restrict the output of {command}
                     to lines that do NOT match {pattern}.

                     {pattern} is a Vim search pattern. Instead of
                     enclosing it in / any non-ID character (see 'isident')
                     can be used, so long as it does not appear in
                     {pattern}.
                     Without the enclosing character the pattern cannot
                     include the bar character. 'ignorecase' is not used.

                     The pattern is matched against the relevant part of
                     the output, not necessarily the whole line. Only some
                     commands support filtering, try it out to check if it
                     works. Some of the commands that support filtering:
                        :#   - filter whole line
                        :clist   - filter by file name or module name
                        :command   - filter by command name
                        :files   - filter by file name
                        :highlight - filter by highlight group
                        :history   - filter by history commands
                        :jumps   - filter by file name
                        :let   - filter by variable name
                        :list   - filter whole line
                        :llist   - filter by file name or module name
                        :marks   - filter by text in the current file,
                                      or file name for other files
                        :oldfiles   - filter by file name
                        :registers - filter by register contents
                                      (does not work multi-line)
                        :set   - filter by option name

                     Only normal messages are filtered, error messages are
                     not.

                                          :sil :silent :silent!
:sil[ent][!] {command} Execute {command} silently. Normal messages will not
                     be given or added to the message history.
                     When [!] is added, error messages will also be
                     skipped, and commands and mappings will not be aborted
                     when an error is detected. v:errmsg is still set.
                     When [!] is not used, an error message will cause
                     further messages to be displayed normally.
                     Redirection, started with :redir, will continue as
                     usual, although there might be small differences.
                     This will allow redirecting the output of a command
                     without seeing it on the screen. Example:

```
:redir >/tmp/foobar
:silent g/Aap/p
:redir END
```

To execute a Normal mode command silently, use the :normal command. For example, to search for a string without messages:

```
:silent exe "normal /path\<CR>"
```

":silent!" is useful to execute a command that may fail, but the failure is to be ignored. Example:

```
:let v:errmsg = ""
:silent! /^begin
:if v:errmsg != ""
: ... pattern was not found
```

":silent" also skips the hit-enter prompt. Dialogs that prompt for user input (confirm(), 'swapfile', …) are never silent.

:uns :unsilent

:uns[ilent] {command} Execute {command} not silently. Only makes a difference when :silent was used to get to this command.
Use this for giving a message even when :silent was used. In this example :silent is used to avoid the message about reading the file and :unsilent to be able to list the first line of each file.

```
:silent argdo unsilent echo expand('%') .. ": " .. getline(1)
```

:verb :verbose

:[count]verb[ose] {command}
Execute {command} with 'verbose' set to [count]. If [count] is omitted one is used. ":0verbose" can be used to set 'verbose' to zero.
The additional use of ":silent" makes messages generated but not displayed.
The combination of ":silent" and ":verbose" can be used to generate messages and check them with v:statusmsg and friends. For example:

```
:let v:statusmsg = ""
:silent verbose runtime foobar.vim
:if v:statusmsg != ""
:  " foobar.vim could not be found
:endif
```

When concatenating another command, the ":verbose" only applies to the first one:

```
:4verbose set verbose | set verbose
```

verbose=4
verbose=0

For logging verbose messages in a file use the 'verbosefile' option.

:verbose-cmd

When 'verbose' is non-zero, listing the value of a Vim option or a key map or an abbreviation or a user-defined function or a command or a highlight group or an autocommand will also display where it was last defined. If they were defined in Lua they will only be located if 'verbose' is set. So Start nvim with -V1 arg to see them. If it was defined manually then there will be no "Last set" message. When it was defined while executing a function, user command or autocommand, the script in which it was defined is reported.

K

[count]K Runs the program given by 'keywordprg' to lookup the word (defined by 'iskeyword') under or right of the cursor. Default is "man". Works like this:

```
:tabnew | terminal {program} {keyword}
```

Special cases:

- If 'keywordprg' begins with ":" it is invoked as

  a Vim command and [count] is passed as the first argument, if present.
- If 'keywordprg' is empty, :help is used.
- When 'keywordprg' is equal to "man", a [count]

  before "K" is inserted after the "man" command and

before the keyword. For example, using "2K" while
the cursor is on "mkdir", results in:

```
!man 2 mkdir
```

- When 'keywordprg' is equal to "man -s", a [count]

  before "K" is inserted after the "-s". If there is
  no count, the "-s" is removed.

K-lsp-default

- The Nvim LSP client sets K to show LSP "hover"

  feature. lsp-defaults

v_K

{Visual}K Like "K", but use the visually highlighted text for
the keyword. Only works when the highlighted text is
not more than one line.

gO

gO Show a filetype-specific, navigable "outline" of the
current buffer. For example, in a help buffer this
shows the table of contents.

Works in help and :Man buffers, or any buffer with
an active LSP client (lsp-defaults).

[N]gs gs :sl :sleep
:[N]sl[eep] [N][m] Do nothing for [N] seconds, or [N] milliseconds if [m]
was given. "gs" always uses seconds.
Default is one second.

```
:sleep       "sleep for one second
:5sleep      "sleep for five seconds
:sleep 100m     "sleep for 100 milliseconds
10gs         "sleep for ten seconds
```

Can be interrupted with CTRL-C.
"gs" stands for "goto sleep".
While sleeping the cursor is positioned in the text,
if at a visible position.
Queued messages are processed during the sleep.

:sl! :sleep!
:[N]sl[eep]! [N][m] Same as above, but hide the cursor.

g==

g== Executes the current code block.

Works in help buffers.

:upt :uptime
:upt[ime] Shows Nvim's uptime.
See also v:starttime.

2. Using Vim like less or more less

If you use the less or more program to view a file, you don't get syntax
highlighting. Thus you would like to use Vim instead. You can do this by
using the shell script "$VIMRUNTIME/scripts/less.sh".

This shell script uses the Vim script "$VIMRUNTIME/scripts/less.vim". It sets
up mappings to simulate the commands that less supports. Otherwise, you can
still use the Vim commands.

This isn't perfect. For example, when viewing a short file Vim will still use
the whole screen. But it works well enough for most uses, and you get syntax
highlighting.

The "h" key will give you a short overview of the available commands.

If you want to set options differently when using less, define the
LessInitFunc in your vimrc, for example:

```
func LessInitFunc()
  set nocursorcolumn nocursorline
endfunc
```

3. Commenting commenting

Nvim supports commenting and uncommenting of lines based on 'commentstring'.

Acting on a single line behaves as follows:

- If the line matches 'commentstring', the comment markers are removed (e.g.

  /*foo*/ is transformed to foo).
- Otherwise the comment markers are added to the current line (e.g. foo is

transformed to /*foo*/). Blank lines are ignored.

Acting on multiple lines behaves as follows:

- If each affected non-blank line matches 'commentstring', then all comment markers are removed.
- Otherwise all affected lines are converted to comments; blank lines are transformed to empty comments (e.g. /**/). Comment markers are aligned to the least indented line.

Matching 'commentstring' does not account for whitespace in comment markers. Removing comment markers is first attempted exactly, with fallback to using markers trimmed from whitespace.

If the filetype of the buffer is associated with a language for which a treesitter parser is installed, then vim.filetype.get_option() is called to look up the value of 'commentstring' corresponding to the cursor position. (This can be different from the buffer's 'commentstring' in case of treesitter-language-injections.)

The following default-mappings are defined:

		gc gc-default
gc{motion}	Comment or uncomment lines covered by {motion}.	
		gcc gcc-default
gcc	Comment or uncomment [count] lines starting at cursor.	
		v_gc v_gc-default
{Visual}gc	Comment or uncomment the selected line(s).	
		o_gc o_gc-default
gc	Text object for the largest contiguous block of non-blank commented lines around the cursor (e.g. gcgc uncomments a comment block; dgc deletes it). Works only in Operator-pending mode.	

Differences between Vim and Vi

1. Limits limits

Vim has only a few limits for the files that can be edited. Vi cannot handle <Nul> characters and characters above 128, has limited line length, many other limits.

Maximum line length	2147483647 characters
Maximum number of lines	2147483647 lines
Maximum file size	2147483647 bytes (2 Gbyte) when a long integer is 32 bits. Much more for 64 bit longs. Also limited by available disk space for the swap-file.

E75

Length of a file path	Unix and Win32: 1024 characters, otherwise 256 characters (or as much as the system supports).
Length of an expanded string option	Unix and Win32: 1024 characters, otherwise 256 characters
Maximum display width	Unix and Win32: 1024 characters, otherwise 255 characters
Maximum lhs of a mapping	50 characters.

Number of different highlighting types: over 30000
Range of a Number variable: -2147483648 to 2147483647 (might be more on 64 bit systems) See also: v:numbermax, v:numbermin and v:numbersize
Maximum length of a line in a tags file: 512 bytes.

E1541

Maximum value for /\U and /\%U: 2147483647 (for 32bit integer).

Information for undo and text in registers is kept in memory, thus when making (big) changes the amount of (virtual) memory available limits the number of undo levels and the text that can be kept in registers. Other things are also kept in memory: Command-line history, error messages for Quickfix mode, etc.

2. The most interesting additions vim-additions

Support for different systems.
Vim can be used on:

- Modern Unix systems (BSD, Linux, etc.)
- Windows (XP SP 2 or greater)
- OS X

Multi level persistent undo. undo
'u' goes backward in time, 'CTRL-R' goes forward again. Set option 'undolevels' to the number of changes to be remembered (default 1000). Set 'undolevels' to 0 for a Vi-compatible one level undo. Set it to -1 for no undo at all.
When all changes in a buffer have been undone, the buffer is not considered changed anymore. You can exit it with :q, without <!>.
When undoing a few changes and then making a new change Vim will create a branch in the undo tree. This means you can go back to any state of the text, there is no risk of a change causing text to be lost forever. undo-tree
The undo information is stored in a file when the 'undofile' option is set. This means you can exit Vim, start Vim on a previously edited file and undo changes that were made before exiting Vim.

Graphical User Interface (GUI). gui
Included support for GUI: menu's, mouse, scrollbars, etc. You can define your own menus. Better support for CTRL/SHIFT/ALT keys in combination with special keys and mouse. Supported for various platforms such as Win32.

Multiple windows and buffers. windows.txt
Vim can split the screen into several windows, each editing a different buffer or the same buffer at a different location. Buffers can still be loaded (and changed) but not displayed in a window. This is called a hidden buffer. Many commands and options have been added for this facility.
Vim can also use multiple tabpages, each with one or more windows. A line with tab labels can be used to quickly switch between these pages.
tabpage

Syntax highlighting. :syntax
Vim can highlight keywords, patterns and other things. This is defined by a number of :syntax commands, and can be made to highlight most languages and file types. A number of files are included for highlighting the most common languages, like C, C++, Java, Pascal, Makefiles, shell scripts, etc. The colors used for highlighting can be defined for ordinary terminals, color terminals and the GUI with the :highlight command. A convenient way to do this is using a :colorscheme command.

The highlighted text can be exported as HTML. convert-to-HTML
Other items that can be highlighted are matches with the search string 'hlsearch', matching parens matchparen and the cursor line and column 'cursorline' 'cursorcolumn'.

Spell checking. spell
When the 'spell' option is set Vim will highlight spelling mistakes. About 50 languages are currently supported, selected with the 'spelllang' option. In source code only comments and strings are checked for spelling.

Folding. folding
A range of lines can be shown as one "folded" line. This allows overviewing a file and moving blocks of text around quickly. Folds can be created manually, from the syntax of the file, by indent, etc.

Diff mode. diff-mode
Vim can show two versions of a file with the differences highlighted. Parts of the text that are equal are folded away. Commands can be used to move text from one version to the other.

Plugins. add-plugin
The functionality can be extended by dropping a plugin file in the right directory. That's an easy way to start using Vim scripts written by others. Plugins can be for all kind of files, or specifically for a filetype.
Packages make this even easier. packages

Asynchronous communication and timers. job-control timer
Vim can exchange messages with other processes in the background. Vim can start a job, communicate with it and stop it. job-control
Timers can fire once or repeatedly and invoke a function to do any work. timer

Repeat a series of commands. g
"q{c}" starts recording typed characters into named register {c}. A subsequent "q" stops recording. The register can then be executed with the "@{c}" command. This is very useful to repeat a complex action.

Flexible insert mode. ins-special-special
The arrow keys can be used in insert mode to move around in the file. This breaks the insert in two parts as far as undo and redo is concerned.

CTRL-O can be used to execute a single Normal mode command. This is almost the same as hitting <Esc>, typing the command and doing a.

Visual mode. Visual-mode
Visual mode can be used to first highlight a piece of text and then give a command to do something with it. This is an (easy to use) alternative to first giving the operator and then moving to the end of the text to be operated upon.
v and V are used to start Visual mode. v works on characters and V on lines. Move the cursor to extend the Visual area. It is shown highlighted on the screen. By typing "o" the other end of the Visual area can be moved. The Visual area can be affected by an operator:

d	delete
c	change
y	yank
> or <	insert or delete indent
!	filter through external program
=	filter through indent
:	start : command for the Visual lines.
gq	format text to 'textwidth' columns
J	join lines
~	swap case
u	make lowercase
U	make uppercase

Block operators. visual-block
With Visual mode a rectangular block of text can be selected. Start Visual mode with CTRL-V. The block can be deleted ("d"), yanked ("y") or its case can be changed ("~", "u" and "U"). A deleted or yanked block can be put into the text with the "p" and "P" commands.

Help system. :help
Help is displayed in a window. The usual commands can be used to move around, search for a string, etc. Tags can be used to jump around in the help files, just like hypertext links. The :help command takes an argument to quickly jump to the info on a subject. <F1> is the quick access to the help system. The name of the help index file can be set with the 'helpfile' option.

Command-line editing and history. cmdline-editing
You can insert or delete at any place in the command-line using the cursor keys. The right/left cursor keys can be used to move forward/backward one character. The shifted right/left cursor keys can be used to move forward/backward one word. CTRL-B/CTRL-E can be used to go to the begin/end of the command-line.
(Vi: can only alter the last character in the line)
(Vi: when hitting <Esc> the command-line is executed. This is unexpected for most people; therefore it was changed in Vim. But when the <Esc> is part of a mapping, the command-line is executed. If you want the Vi behaviour also when typing <Esc>, use ":cmap ^V<Esc>

^V^M")

cmdline-history

The command-lines are remembered. The up/down cursor keys can be used to recall previous command-lines. The 'history' option can be set to the number of lines that will be remembered. There is a separate history for commands and for search patterns.

Command-line completion. cmdline-completion

While entering a command-line (on the bottom line of the screen) <Tab> can be typed to complete

what **example**

- command :e<Tab>
- tag :ta scr<Tab>
- option :set sc<Tab>
- option value :set hf=<Tab>
- file name :e ve<Tab>
- etc.

If there are multiple matches, CTRL-N (next) and CTRL-P (previous) will walk through the matches. <Tab> works like CTRL-N, but wraps around to the first match.

The 'wildchar' option can be set to the character for command-line completion, <Tab> is the default. CTRL-D can be typed after an (incomplete) wildcard; all matches will be listed. CTRL-A will insert all matches. CTRL-L will insert the longest common part of the matches.

Insert-mode completion. ins-completion

In Insert mode the CTRL-N and CTRL-P keys can be used to complete a word that appears elsewhere. i_CTRL-N

With CTRL-X another mode is entered, through which completion can be done for:

i_CTRL-X_CTRL-F	file names
i_CTRL-X_CTRL-K	words from 'dictionary' files
i_CTRL-X_CTRL-T	words from 'thesaurus' files
i_CTRL-X_CTRL-I	words from included files
i_CTRL-X_CTRL-L	whole lines
i_CTRL-X_CTRL-]	words from the tags file
i_CTRL-X_CTRL-D	definitions or macros
i_CTRL-X_CTRL-O	Omni completion: clever completion specifically for a file type
i_CTRL-X_CTRL-R	contents from registers

etc.

Long line support. 'wrap' 'linebreak'

If the 'wrap' option is off, long lines will not wrap and only part of them will be shown. When the cursor is moved to a part that is not shown, the screen will scroll horizontally. The minimum number of columns to scroll can be set with the 'sidescroll' option. The zh and zl commands can be used to scroll sideways.
Alternatively, long lines are broken in between words when the 'linebreak' option is set. This allows editing a single-line paragraph conveniently (e.g. when the text is later read into a DTP program). Move the cursor up/down with the gk and gj commands.

Text formatting. formatting

The 'textwidth' option can be used to automatically limit the line length. This supplements the 'wrapmargin' option of Vi, which was not very useful. The gq operator can be used to format a piece of text (for example, ggqap formats the current paragraph). Commands for text alignment: :center, :left and :right.

Extended search patterns. pattern

There are many extra items to match various text items. Examples:
A "\n" can be used in a search pattern to match a line break.
"x\{2,4}" matches "x" 2 to 4 times.
"\s" matches a white space character.

Directory, remote and archive browsing. dir

Vim can browse the file system. Simply edit a directory. Move around in the list with the usual commands and press <Enter> to go to the directory or file under the cursor.
This also works for remote files over ftp, http, ssh, etc.
Zip and tar archives can also be browsed. tar zip

Edit-compile-edit speedup. quickfix

The :make command can be used to run the compilation and jump to the first error. A file with compiler error messages is interpreted. Vim jumps to the first error.

Each line in the error file is scanned for the name of a file, line number and error message. The 'errorformat' option can be set to a

list of scanf-like strings to handle output from many compilers.

The :cn command can be used to jump to the next error.
:cl lists all the error messages. Other commands are available.
The 'makeef' option has the name of the file with error messages.
The 'makeprg' option contains the name of the program to be executed
with the :make command.
The 'shellpipe' option contains the string to be used to put the
output of the compiler into the errorfile.

Finding matches in files. :vimgrep
Vim can search for a pattern in multiple files. This uses the
advanced Vim regexp pattern, works on all systems and also works to
search in compressed files.

Improved indenting for programs. 'cindent'
When the 'cindent' option is on the indent of each line is
automatically adjusted. C syntax is mostly recognized. The indent
for various styles can be set with 'cinoptions'. The keys to trigger
indenting can be set with 'cinkeys'.

Comments can be automatically formatted. The 'comments' option can be
set to the characters that start and end a comment. This works best
for C code, but also works for e-mail (">" at start of the line) and
other types of text. The = operator can be used to re-indent
lines.

For many other languages an indent plugin is present to support
automatic indenting. 30.3

Searching for words in included files. include-search
The [i command can be used to search for a match of the word under
the cursor in the current and included files. The 'include' option
can be set to a pattern that describes a command to include a file
(the default is for C programs).
The [I command lists all matches, the [_CTRL-I command jumps to
a match.
The [d, [D and [_CTRL-D commands do the same, but only for
lines where the pattern given with the 'define' option matches.

Automatic commands. autocommand
Commands can be automatically executed when reading a file, writing a
file, jumping to another buffer, etc., depending on the file name.
This is useful to set options and mappings for C programs,
documentation, plain text, e-mail, etc. This also makes it possible
to edit compressed files.

Scripts and Expressions. expression
Commands have been added to form up a powerful script language.
:if   Conditional execution, which can be used for example
                to set options depending on the value of $TERM.
:while   Repeat a number of commands.
:for   Loop over a list.
:echo   Print the result of an expression.
:let   Assign a value to an internal variable, option, etc.
                Variable types are Number, String, List and Dictionary.
:execute   Execute a command formed by an expression.
:try   Catch exceptions.
etc., etc. See eval.
Debugging and profiling are supported. debug-scripts profile
If this is not enough, an interface is provided to Python.

Viminfo.
The command-line history, marks and registers can be stored in a file
that is read on startup. This can be used to repeat a search command
or command-line command after exiting and restarting Vim. It is also
possible to jump right back to where the last edit stopped with '0.
The 'viminfo' option can be set to select which items to store in the
.viminfo file. This is off by default.

Mouse support. mouse-using
The mouse is supported in the GUI version, in an xterm for Unix, for
BSDs with sysmouse, for Linux with gpm, and for Win32. It can be used
to position the cursor, select the visual area, paste a register, etc.

Usage of key names. <> key-notation
Special keys now all have a name like <Up>, <End>, etc.
This name can be used in mappings, to make it easy to edit them.

Editing binary files. edit-binary
Vim can edit binary files. You can change a few characters in an
executable file, without corrupting it. Vim doesn't remove NUL
characters (they are represented as <NL> internally).
-b   command-line argument to start editing a binary file
'binary'   Option set by -b. Prevents adding an <EOL> for the
                last line in the file.

Multi-language support. multi-lang
Files in double-byte or multibyte encodings can be edited. There is
UTF-8 support to be able to edit various languages at the same time,
without switching fonts. UTF-8
Messages and menus are available in different languages.

Move cursor beyond lines.
When the 'virtualedit' option is set the cursor can move all over the
screen, also where there is no text. This is useful to edit tables
and figures easily.

Differences between Nvim and Vim

Nvim differs from Vim in many ways, although editor and Vimscript (not Vim9script) features are mostly identical. This document is a complete and centralized reference of the differences.

Configuration

nvim-config

User configuration and data files are found in standard base-directories (see also $NVIM_APPNAME). Note in particular:

- Use `$XDG_CONFIG_HOME/nvim/init.vim` instead of `.vimrc` for your config.
- Use `$XDG_CONFIG_HOME/nvim` instead of `.vim` to store configuration files.
- Use `$XDG_STATE_HOME/nvim/shada/main.shada` instead of `.viminfo` for persistent session information. shada

Defaults

defaults **nvim-defaults**

- Filetype detection is enabled by default. This can be disabled by adding ":filetype off" to init.vim.
- Syntax highlighting is enabled by default. This can be disabled by adding ":syntax off" to init.vim.
- Default color scheme has been updated. This can result in color schemes looking differently due to them relying on how highlight groups are defined by default. Add ":colorscheme vim" to init.vim or ":source $VIMRUNTIME/colors/vim.lua" to your color scheme file to restore the old default links and colors. See :highlight for a list of highlight groups colorschemes should set.
- 'autoindent' is enabled
- 'autoread' is enabled (works in all UIs, including terminal)
- 'background' defaults to "dark" (unless set automatically by the terminal/UI)
- 'backupdir' defaults to .,~/.local/state/nvim/backup// (xdg), auto-created
- 'belloff' defaults to "all"
- 'comments' includes "fb:•"
- 'commentstring' defaults to ""
- 'compatible' is always disabled
- 'complete' excludes "i"
- 'completeopt' defaults to "menu,popup"
- 'define' defaults to "". The C ftplugin sets it to "^\\s*#\\s*define"
- 'diffopt' includes "linematch:40"
- 'directory' defaults to ~/.local/state/nvim/swap// (xdg), auto-created
- 'display' defaults to "lastline"
- 'encoding' is UTF-8 (cf. 'fileencoding' for file-content encoding)
- 'fillchars' defaults (in effect) to "vert:│,fold:·,foldsep:│"
- 'formatoptions' defaults to "tcqj"
- 'grepprg' uses the -H and -I flags for regular grep, and defaults to using ripgrep if available
- 'hidden' is enabled
- 'history' defaults to 10000 (the maximum)
- 'hlsearch' is enabled
- 'include' defaults to "". The C ftplugin sets it to "^\\s*#\\s*include"
- 'incsearch' is enabled
- 'isfname' does not include ":" (on Windows). Drive letters are handled correctly without it. (Use gF for filepaths suffixed with ":line:col").
- 'joinspaces' is disabled
- 'jumpoptions' defaults to "clean"
- 'langnoremap' is enabled
- 'langremap' is disabled
- 'laststatus' defaults to 2 (statusline is always shown)
- 'listchars' defaults to "tab:> ,trail:-,nbsp:+"
- 'maxsearchcount' defaults to 999
- 'mouse' defaults to "nvi", see default-mouse for details
- 'mousemodel' defaults to "popup_setpos"
- 'nrformats' defaults to "bin,hex"
- 'path' defaults to ".,,". The C ftplugin adds "/usr/include" if it exists.
- 'sessionoptions' includes "unix,slash", excludes "options"
- 'shelltemp' is disabled
- 'shortmess' includes "CF", excludes "S"
- 'sidescroll' defaults to 1
- 'smarttab' is enabled
- 'spellfile' defaults to `stdpath("data")..."/site/spell/"`
- 'startofline' is disabled
- 'switchbuf' defaults to "uselast"
- 'tabpagemax' defaults to 50
- 'tags' defaults to "./tags;,tags"
- 'termguicolors' is enabled by default if Nvim can detect support from the host terminal
- 'ttimeout' is enabled
- 'ttimeoutlen' defaults to 50
- 'ttyfast' is set by default, but it can be unset during startup by setting the environment variable `NVIM_NOTTYFAST` to adjust the startup sequence for slow environments (such as ssh).
- 'undodir' defaults to ~/.local/state/nvim/undo// (xdg), auto-created
- 'viewoptions' includes "unix,slash", excludes "options"
- 'viminfo' includes "!"
- 'wildoptions' defaults to "pum,tagfile"
- dir plugin is enabled, so editing a directory shows its contents in a buffer with 'filetype' set to "directory".
- editorconfig plugin is enabled, .editorconfig settings are applied.
- man.lua plugin is enabled, so :Man is available by default.

- |matchit| plugin is enabled. To disable it in your config:

```
:let loaded_matchit = 1
```

- package-spellfile plugin is enabled, spellfiles are installed by default if missing.
- g:vimsyn_embed defaults to "l" to enable Lua highlighting

DEFAULT MOUSE

default-mouse disable-mouse By default the mouse is enabled. This means scroll-mouse-wheel will scroll the window instead of moving the cursor; <LeftMouse> click places the cursor; and <RightMouse> click opens the default popup-menu with standard actions.

Mouse is NOT enabled in Cmdline-mode or the more-prompt, so you can temporarily disable it just by typing ":". Or if you want to partially or fully disable the mouse or popup-menu, do any of the following:

- Disable mouse completely by unsetting the 'mouse' option:

```
set mouse=
```

- Change the 'mousemodel', so <RightMouse> extends selection instead of showing the popup-menu:

```
set mousemodel=extend
```

- Map <A-LeftMouse> so that it temporarily disables mouse until the cursor moves:

```
nnoremap <A-LeftMouse> <Cmd>
  \ set mouse=<Bar>
  \ echo 'mouse OFF until next cursor-move'<Bar>
  \ autocmd CursorMoved * ++once set mouse&<Bar>
  \ echo 'mouse ON'<CR>
```

To remove the default popup-menu without disabling mouse:

```
aunmenu PopUp
autocmd! nvim.popupmenu
```

To remove only the "How-to disable mouse" menu item (and its separator):

```
aunmenu PopUp.How-to\ disable\ mouse
aunmenu PopUp.-2-
```

DEFAULT MAPPINGS

default-mappings

Nvim creates the following default mappings at startup. You can disable any of these in your config by simply removing the mapping, e.g. ":unmap Y". If you never want any default mappings, call :mapclear early in your config.

- Y Y-default
- <C-U> i_CTRL-U-default
- <C-W> i_CTRL-W-default
- <C-L> CTRL-L-default
- & &-default
- - dir-mappings
- @ v_@-default
- # v_#-default
- * v_star-default
- gc gc-default v_gc-default o_gc-default

- <C-W>d CTRL-W_d-default
- [q]q [Q]Q [_CTRL-Q]_CTRL-Q
- [l]l [L]L [_CTRL-L]_CTRL-L
- [t]t [T]T [_CTRL-T]_CTRL-T
- [a]a [A]A
- [b]b [B]B
- [<Space>]<Space>
- LSP defaults lsp-defaults
  - K K-lsp-default
  - gr prefix gr-default
    - gra gri grn grr grt
  - <C-S> i_CTRL-S
- Treesitter defaults treesitter-defaults
  - v_an v_in
  - v_]n v_[n

DEFAULT AUTOCOMMANDS

default-autocmds

Default autocommands exist in the following groups. Use ":autocmd! {group}" to remove them and ":autocmd {group}" to see how they're defined.

nvim.terminal:

- BufReadCmd: Treats "term://" buffers as terminal buffers. terminal-start
- TermClose: A terminal buffer started with no arguments (which thus uses 'shell') and which exits with no error is closed automatically.
- TermClose: Displays the "[Process exited]" virtual text.
- TermRequest: The terminal emulator responds to OSC background and foreground requests, indicating (1) a black background and white foreground when Nvim option 'background' is "dark" or (2) a white background and black foreground when 'background' is "light". While this may not reflect the actual foreground/background color, it permits 'background' to be retained for a nested Nvim instance running in the terminal emulator.
- TermRequest: Nvim will create extmarks for shells which annotate their prompts with OSC 133 escape sequences, enabling users to quickly navigate between prompts using [[and]].
- TermOpen: Sets default options and mappings for terminal buffers:
  - 'nomodifiable'
  - 'undolevels' set to -1
  - 'textwidth' set to 0
  - 'nowrap'
  - 'nolist'
  - 'nonumber'
  - 'norelativenumber'
  - 'signcolumn' set to "no"
  - 'foldcolumn' set to "0"
  - 'winhighlight' uses hl-StatusLineTerm and hl-StatusLineTermNC in place of hl-StatusLine and hl-StatusLineNC
  - [[and]] to navigate between shell prompts

nvim.cmdwin:

- CmdwinEnter: Limits syntax sync to maxlines=1 in the cmdwin.

nvim.swapfile:

- SwapExists: Skips the swapfile prompt (sets v:swapchoice to "e") when the swapfile is owned by a running Nvim process. Shows W325 "Ignoring swapfile..." message.

nvim.exrc:

- VimEnter: Extend 'exrc' to also search for project-local configuration files in all parent directories.

nvim.progress:

- Progress: Display native progress bars in the TUI using the OSC 9;4 escape sequence.

New Features

nvim-features

MAJOR COMPONENTS

- API API
- Command atoms CmdAtom
- Job control job-control
- LSP framework lsp
- Lua scripting lua -l
- Multicursor multicursor
- Parsing engine treesitter
- Plugin manager vim.pack
- Providers
  - Clipboard provider-clipboard
  - Node.js plugins provider-nodejs
  - Python plugins provider-python
  - Ruby plugins provider-ruby
- Remote --remote-ui :connect :detach
- Remote plugins remote-plugin
- Shared data shada
- Terminal emulator terminal
- UI ui --listen --server
- Vimscript parser nvim_parse_expression()
- XDG base directories xdg

USER EXPERIENCE

Working intuitively and consistently is a major goal of Nvim.

feature-compile

- Nvim always includes ALL features, in contrast to Vim (which ships various combinations of 100+ optional features). feature-compile Think of it as a leaner version of Vim's "HUGE" build. This reduces surface area for bugs, and removes a common source of confusion and friction for users.
- Nvim avoids features that cannot be provided on all platforms; instead that is delegated to external plugins/extensions. E.g. the -X platform-specific option is "sometimes" available in Vim (with potential surprises: https://stackoverflow.com/q/14635295).
- Vim's internal test functions (test_autochdir(), test_settime(), etc.) are not exposed (nor implemented); instead Nvim has a robust API.
- Behaviors, options, documentation are removed if they cost users more time than they save.

Usability details have been improved where the benefit outweighs any backwards-compatibility cost. Some examples:

- Directories for 'directory' and 'undodir' are auto-created.
- Terminal features such as 'guicursor' are enabled where possible.
- Various "nvim" cli-arguments were redesigned.

Some features are built in that otherwise required external plugins:

- Highlighting the yanked region, see vim.hl.

ARCHITECTURE

The Nvim UI is "decoupled" from the core editor: all UIs, including the builtin TUI are just plugins that connect to a Nvim server (via --server or --embed). Multiple UI clients can :connect to the same editor server.

External plugins run in separate processes. remote-plugin This improves stability and allows those plugins to work without blocking the editor. Even "legacy" Python and Ruby plugins which use the old Vim interfaces (if_pyth, if_ruby) run out-of-process, so they cannot crash Nvim.

Platform and I/O facilities are built upon libuv. Nvim benefits from libuv features and bug fixes, and other projects benefit from improvements to libuv by Nvim developers. This enables features such as vim.wait() and vim.uv.

FEATURES

Command-line:
- The expression prompt (@=, c_CTRL-R_=, i_CTRL-R_=) is highlighted using a built-in Vimscript expression parser. expr-highlight
- E5408 E5409 input(), inputdialog() support custom highlighting. input()-highlight
- (Experimental) g:Nvim_color_cmdline Command-line (:) is colored by callback defined in `g:Nvim_color_cmdline` (this callback is for testing only, and will be removed in the future).
- cmdwin (q:, q/, q?, c_CTRL-F) is a "normal" buffer+window, instead of a nested modal loop. API and Lua callbacks can run while it is open. The cmdwin-char is shown via 'statuscolumn'.

Commands:
- :bcd
- :checkhealth
- :connect
- :detach
- :diffget, :diffput (do, dp) can be . repeated.
- :drop is always available
- :EditQuery
- :Inspect
- :InspectTree
- :log
- :lsp
- :Man is available by default, with many improvements such as completion
- :match can be invoked before highlight group is defined
- :packdel
- :packupdate
- :restart
- :source works with Lua
- :trust
- User commands can support :command-preview to show results as you type
- :write with "++p" flag creates parent directories.
- :update command writes new file buffers even when unmodified.
- :uptime

Editor:
- ins-repeat replays the full Insert session, including cursor-moves: "iab<Left>c<Esc>." produces "acb", not "c".
- visual-repeat is "semantic" instead of "fixed-size". If you prefer Vim's "fixed-size" Visual-repeat, see visual-fixed-size.
- Interactive Ex-mode is implemented as persistent, insert-mode cmdwin.
- prompt-buffer supports multiline input/paste, undo/redo, and o/O normal commands.
- i_CTRL-R inserts named/clipboard registers (A-Z,a-z,0-9+) literally, like pasting instead of like user input. Improves performance, avoids broken formatting. To get the old behavior you can use `<C-R>=@x`.

Events (autocommands):
- Fixed inconsistent behavior in execution of nested autocommands #23368
- InsertCharPre is not triggered for stuffed text (., redo, i_CTRL-R, i_CTRL-A), which also skips mappings and abbreviations.
- OptionSet is triggered for 'modified' when writing a file, undoing changes, or using :set modified.
- Progress
- RecordingEnter
- RecordingLeave
- SearchWrapped
- Signal
- TabMoved
- TabNewEntered
- TermClose
- TermOpen
- TermRequest
- TermResponse is fired for DCS, OSC, and APC sequences received from the terminal, in addition to the Primary Device Attributes response. v:termresponse
- UIEnter
- UILeave

Functions:
- dictwatcheradd() notifies a callback whenever a Dict is modified

- dictwatcherdel()
- menu_get()
- msgpackdump(), msgpackparse() provide msgpack de/serialization
- stdpath()
- system(), systemlist() can run {cmd} directly (without 'shell')
- matchadd() can be called before highlight group is defined
- tempname() tries to recover if the Nvim tempdir disappears.
- writefile() with "p" flag creates parent directories.
- prompt_getinput()
- prompt_appendbuf()

Highlight groups:
- highlight-blend controls blend level for a highlight group
- expr-highlight highlight groups (prefixed with "Nvim")
- hl-NormalFloat highlights floating window
- hl-FloatBorder highlights border of a floating window
- hl-FloatTitle highlights title of a floating window
- hl-FloatFooter highlights footer of a floating window
- hl-NormalNC highlights non-current windows
- hl-MsgArea highlights messages/cmdline area
- hl-MsgSeparator highlights separator for scrolled messages
- hl-OkMsg
- hl-StderrMsg
- hl-StdoutMsg
- hl-Substitute
- hl-TermCursor
- hl-WinSeparator highlights window separators
- hl-Whitespace highlights 'listchars' whitespace
- hl-WinBar highlights 'winbar'
- hl-WinBarNC highlights non-current window 'winbar'

Input/Mappings:
- ALT (META) chords always work (even in the TUI). Map <M- with any key: <M-1>, <M-BS>, <M-Del>, <M-Ins>, <M-/>, <M-\>, <M-Space>, <M-Enter>, etc.
  - Case-sensitive: <M-a> and <M-A> are two different keycodes.
- ALT may behave like <Esc> if not mapped. i_ALT v_ALT c_ALT

Normal commands:
- gO shows a filetype-defined "outline" of the current buffer.
- gQ restores multicursors.
- Q adds a multicursor instead of switching to Ex mode.
- [count]q: enters Ex-mode.
- ZR performs :restart
- v_al selects the whole buffer; v_il selects the current line without leading or trailing white space.

Options:

- :set {option}< removes local value for all global-local options.
- :setlocal {option}< copies global value to local value for all options.
- 'ambiwidth' cannot be set to empty.
- 'autoread' works in the terminal (if it supports "focus" events)
- 'background' cannot be set to empty.
- 'completeopt' flag "preselect" selects first completion item that has the "preselect" attribute set.
- 'cpoptions' flags: cpo-_
- 'eadirection' cannot be set to empty.
- 'exrc' searches for ".nvim.lua", ".nvimrc", or ".exrc" files. The user is prompted whether to trust the file.
- 'fileformat' cannot be set to empty.
- 'fillchars' flags: "msgsep", "horiz", "horizup", "horizdown", "vertleft", "vertright", "verthoriz"
- 'foldcolumn' supports up to 9 dynamic/fixed columns
- 'guicursor' works in the terminal (TUI)
- 'inccommand' shows interactive results for :substitute-like commands and :command-preview commands
- 'isident' does not affect environment variable name parsing. expr-env
- 'jumpoptions'
  - "view" tries to restore mark-view when moving through the jumplist, changelist, alternate-file, and mark-motions.
  - "clean" removes unloaded buffers from the jumplist.
- 'langmap' supports multibyte chars.
- 'laststatus' global statusline support
- 'mousemodel' cannot be set to empty.
- 'mousescroll' amount to scroll by when scrolling with a mouse
- 'pumblend' pseudo-transparent popupmenu
- 'scrollback'
- 'shortmess'
  - "F" flag does not affect output from autocommands.
  - "q" flag fully hides macro recording message.
- 'showcmdloc' cannot be set to empty.
- 'signcolumn' can show multiple signs (dynamic or fixed columns)
- 'statuscolumn' full control of columns using 'statusline' format
- 'statusline' default is exposed as a statusline expression.
- 'statusline' and related options apply %= and %< to item groups.
- 'splitkeep' cannot be set to empty.

- 'tabline' middle-click on tabpage label closes tabpage, and %@Func@foo%X can call any function on mouse-click
- 'termpastefilter'
- 'ttimeout', 'ttimeoutlen' behavior was simplified
- 'winblend' pseudo-transparency in floating windows api-floatwin
- 'winhighlight' window-local highlights
- 'busy' busy status for buffers
- 'messagesopt' added progress:c to control if progress messages are shown in cmdline

Performance:
- Signs are implemented using Nvim's internal "marktree" (btree) structure.
- Folds are not updated during insert-mode.

Providers:
- If a Python interpreter is available on your $PATH, :python and :python3 are always available. See provider-python.

Shell:
- Shell output (:!, :make, ...) is always routed through the UI, so it cannot "mess up" the screen. (You can still use "chansend(v:stderr,...)" if you want to mess up the screen :)
- Nvim throttles (skips) messages from shell commands (:!, :grep, :make) if there is too much output. No data is lost, this only affects display and improves performance. :terminal output is never throttled.
- :! does not support "interactive" commands. Use :terminal instead. (GUI Vim has a similar limitation, see ":help gui-pty" in Vim.)
- :!start is not special-cased on Windows.
- system() does not support writing/reading "backgrounded" commands. E5677

Signs:
- 'signcolumn' can show multiple signs.
- Signs are removed if the associated line is deleted.
- Signs placed twice with the same identifier in the same group are moved.

Startup:
- -e and -es invoke the same "improved Ex mode" as -E and -Es.
- -E and -Es read stdin as text (into buffer 1).
- -es and -Es act as a generic "script mode":
  - Exits automatically, don't need "-c qa!".
  - Skips swap-file dialog.
  - Disables swapfile, shada.
  - Various "POSIX Ex" quirks were dropped.
- -l Executes Lua scripts non-interactively.
- -s reads Normal commands from stdin if the script name is "-".
- Reading text (instead of commands) from stdin --:
  - works by default: "-" file is optional
  - works in more cases: -Es, file args

TUI: :set-termcap
- Start Nvim with 'verbose' level 3 to show terminal capabilities:

```
nvim -V3
```

'term' E529 E530 E531
- 'term' reflects the terminal type derived from $TERM and other environment checks. Use `:echo &term` to get its value. For debugging only; not reliable during startup.
  - **Note:** If you want to detect when Nvim is running in a terminal, use `has('gui_running')` has() or see nvim_list_uis() for an example of how to inspect the UI channel.
- Nvim might optionally be compiled with unibilium, in which case the terminfo database will be used. Otherwise, or if the terminal was not found in the database, a table of builtin terminal definitions will be used.
- Nvim will use 256-colour capability on Linux virtual terminals. Vim uses only 8 colours plus bright foreground on Linux VTs.
- Vim combines what is in its builtin-terms with what it reads from terminfo, and has a 'ttybuiltin' setting to control how that combination works. Nvim uses one or the other, it does not attempt to merge the two.

UI/Display:
- messages: When showing messages longer than 'cmdheight', only scroll the message lines, not the entire screen. The separator line is decorated by hl-MsgSeparator and the "msgsep" flag of 'fillchars'. msgsep

Variables:
- v:progpath is always absolute ("full")
- v:windowid is always available (for use by external UIs)
- OptionSet autocommand args v:option_new, v:option_old,
- v:option_oldlocal, v:option_oldglobal have the type of the option instead of always being strings. v:option_old is now the old global value for all global-local options, instead of just string global-local options.

Vimscript:
- :redir nested in execute() works.

Upstreamed features nvim-upstreamed

These Nvim features were later integrated into Vim.

- 'diffopt' "linematch" feature
- 'fillchars' flags: "eob"
- 'jumpoptions' "stack" behavior
- 'wildoptions' flags: "pum" enables popupmenu for wildmode completion
- <Cmd>
- WinClosed

- WinScrolled
- :sign-define "numhl" argument
- :source works with anonymous (no file) scripts
- 'statusline' supports unlimited alignment sections
- vim-tutor-mode
- Lua: `require()` also searches for modules in 'runtimepath'.
- Lua: vim.g, vim.w, vim.b, vim.t, vim.v, vim.fn, vim.call()
- Visual selection highlights the character at cursor. visual-use

Other changes

nvim-changed

This section documents various low-level behavior changes.

mkdir() behaviour changed:
- 1. Assuming /tmp/foo does not exist and /tmp can be written to mkdir('/tmp/foo/bar', 'p', 0700) will create both /tmp/foo and /tmp/foo/bar with 0700 permissions. Vim mkdir will create /tmp/foo with 0755.
- 2. If you try to create an existing directory with `'p'` (e.g. mkdir('/', 'p')) mkdir() will silently exit. In Vim this was an error.
- 3. mkdir() error messages now include strerror() text when mkdir fails.

string() and :echo behaviour changed:
- 1. No maximum recursion depth limit is applied to nested container structures.
- 2. string() fails immediately on nested containers, not when recursion limit was exceeded.
- 3. When :echo encounters duplicate containers like

```
let l = []
echo [l, l]
```

  it does not use "[...]" (was: "[[], [...]]", now: "[[], []]"). "..." is only used for recursive containers.
- 4. :echo printing nested containers adds "@level" after "..." designating the level at which recursive container was printed: :echo-self-refer. Same thing applies to string() (though it uses construct like "{E724@level}"), but this is not reliable because string() continues to error out.
- 5. Stringifyed infinite and NaN values now use str2float() and can be evaled back.
- 6. (internal) Trying to print or stringify VAR_UNKNOWN in Vim results in nothing, E908, in Nvim it is internal error.

json_decode() behaviour changed:
- 1. It may output msgpack-special-dict.
- 2. msgpack-special-dict is emitted also in case of duplicate keys, while in Vim it errors out.
- 3. It accepts only valid JSON. Trailing commas are not accepted.

json_encode() behaviour slightly changed: now msgpack-special-dict values are accepted, but v:none is not.

Viminfo text files were replaced with binary (messagepack) shada files. Additional differences:

- shada-c has no effect.
- shada-s now limits size of every item and not just registers.
- 'viminfo' option got renamed to 'shada'. Old option is kept as an alias for compatibility reasons.
- :wviminfo was renamed to :wshada, :rviminfo to :rshada. Old commands are still kept.
- ShaDa file format was designed with forward and backward compatibility in mind. shada-compatibility
- Some errors make ShaDa code keep temporary file in-place for user to decide what to do with it. Vim deletes temporary file in these cases. shada-error-handling
- ShaDa file keeps search direction (v:searchforward), viminfo does not.

printf() returns something meaningful when used with `%p` argument: in Vim it used to return useless address of the string (strings are copied to the newly allocated memory all over the place) and fail on types which cannot be coerced to strings. See id() for more details, currently it uses `printf("%p", {expr})` internally.

c_CTRL-R pasting a non-special register into cmdline omits the last <CR>.

CursorMoved triggers when moving between windows.

Lua interface (lua.txt):
- `:lua print("a\0b")` will print a^@b, like with `:echomsg "a\nb"` . In Vim that prints a and b on separate lines, exactly like `:lua print("a\nb")` .
- `:lua error('TEST')` emits the error:

```
E5108: Lua: [string "<Vimscript compiled string>"]:1: TEST
```

  whereas Vim emits only "TEST".
- Lua has direct access to Nvim API via `vim.api`.

Commands:
- :doautocmd does not warn about "No matching autocommands".
- :wincmd accepts a count.
- `:write!` does not show a prompt if the file was updated externally.
- := does not accept ex-flags. With an arg it is equivalent to :lua=

Command-line:
- The meanings of arrow keys do not change depending on 'wildoptions'.

Functions:
- input() and inputdialog() support for each other's features (return on cancel and completion respectively) via dictionary argument (replaces all other arguments if used), and "cancelreturn" can have any type if passed in a dictionary.
- input() and inputdialog() support user-defined cmdline highlighting.

Highlight groups:
- hl-ColorColumn, hl-CursorColumn are lower priority than most other groups

- hl-CursorLine is low-priority unless foreground color is set
- hl-VertSplit superseded by hl-WinSeparator
- Highlight groups names are allowed to contain `@` characters.
  - It is an error to define a highlight group with a name that doesn't match the regexp `[a-zA-Z0-9_.@-]*` (see group-name).
- hl-StatusLineTerm hl-StatusLineTermNC are implemented as 'winhighlight' window-local highlights which are set by the default TermOpen handler.
- The ins-completion-menu has cascading highlight styles. hl-PmenuSel and hl-PmenuMatch both inherit from hl-Pmenu, and hl-PmenuMatchSel inherits highlights from both hl-PmenuSel and hl-PmenuMatch.

Macro (recording) behavior:
- Replay of a macro recorded during :lmap produces the same actions as when it was recorded. In Vim if a macro is recorded while using :lmap'ped keys then the behaviour during record and replay differs.
- 'keymap' is implemented via :lmap instead of :lnoremap so that you can use macros and 'keymap' at the same time. This also means you can use :imap on the results of keys from 'keymap'.

Mappings:
- Creating a mapping for a simplifiable key (e.g. <C-I>) doesn't replace an existing mapping for its simplified form (e.g. <Tab>).
- "#" followed by a digit doesn't stand for a function key at the start of the lhs of a mapping.

Marks:
- undo does not restore a mark that you moved (m, :mark) after the change being undone; the mark shifts with the text it was moved to, the same as a mark the change never touched. Vim restores its old (wrong) position. Marks moved by the change itself are still restored.
- An operator on a target that creates a Visual selection ("cgn") does not change '< '>. gv

Motion:
- The jumplist avoids useless/phantom jumps.

Syntax highlighting:
- syncolor.vim has been removed. Nvim now sets up default highlighting groups automatically for both light and dark backgrounds, regardless of whether or not syntax highlighting is enabled. This means that :syntax-on and :syntax-enable are now identical. Users who previously used an after/syntax/syncolor.vim file should transition that file into a colorscheme. :colorscheme

Vimscript compatibility:
- `count` does not alias to v:count
- `errmsg` does not alias to v:errmsg
- `shell_error` does not alias to v:shell_error
- `this_session` does not alias to v:this_session

Working directory (Vim implemented some of these after Nvim):
- DirChanged and DirChangedPre can be triggered when switching to another window or tab.
- getcwd() and haslocaldir() may throw errors if the tabpage, window, or buffer cannot be found.
- haslocaldir() checks for tab-local directory if and only if `-1` is passed as window number, and its only possible returns values are 0 and 1.
- `getcwd(-1)` is equivalent to `getcwd(-1, 0)` instead of returning the global working directory. Use `getcwd(-1, -1)` to get the global working directory.

Options:
- 'titlestring' uses printf-style '%' items (see: 'statusline') to implement the default behaviour. The implementation is equivalent to setting 'titlestring' to `%t%(\ %M%)%(\ \(%{expand(\"%:~:h\")}\)%)%a\ -\ Nvim`.

packages:
- "start" packages are not explicitly reported in 'runtimepath' (though they are still searched for runtime files). See runtime-search-path

Missing features

nvim-missing

These legacy Vim features are not yet implemented:

- :gui
- 'browsedir' 'bsdir'
- 'completepopup'
- 'guioptions' 'go'
- 'guitablabel' 'gtl'
- 'guitabtooltip' 'gtt'
- 'mouseshape' 'mouses'

Removed legacy features

nvim-removed

These Vim features were intentionally removed from Nvim.

Aliases:
- ex (alias for "nvim -e")
- exim (alias for "nvim -E")
- gex (GUI)
- gview (GUI)
- gvim (GUI)
- gvimdiff (GUI)
- rgview (GUI)
- rgvim (GUI)
- rview
- rvim
- view (alias for "nvim -R")
- vimdiff (alias for "nvim -d" diff-mode)

Commands:

- :behave
- :fixdel
- :gvim
- hardcopy `:hardcopy` was removed. Instead, use `:TOhtml` and print the resulting HTML using a web browser or other HTML viewer.
- :helpfind
- :mode (no longer accepts an argument)
- :open
- :Print
- :promptfind
- :promptrepl
- :scriptversion (always version 1)
- :shell
- :smile
- :tearoff
- :cstag
- :cscope
- :lcscope
- :scscope
- :Vimuntar
- `:TOhtml` was replaced by a Lua version (with various differences)

Compile-time features:
- Emacs tags support
- X11 integration (see x11-selection)

Editor:
- c_CTRL-F cannot enter cmdwin from the expr-register prompt.
- cscope support was removed in favour of plugin-based solutions such as: https://github.com/dhananjaylatkar/cscope_maps.nvim
- popup-window : Use floating-windows instead.
- spellfile.vim : Replaced by package-spellfile.
- textprop : Use extmarks instead.

Eval:
- Vim9script (the Vim 9+ flavor of Vimscript) is not supported.
- cscope_connection()
- err_teapot()
- js_encode()
- js_decode()
- listener_add() , etc: use api-buffer-updates-lua instead.
- redraw_listener_add() , etc: use nvim_set_decoration_provider() instead.
- v:none (used by Vim to represent JavaScript "undefined"); use v:null instead.
- v:sizeofint
- v:sizeoflong
- v:sizeofpointer

Events:
- SafeStateAgain
- SigUSR1 Use Signal to detect `SIGUSR1` signal instead.

Options:
- 'aleph' 'al'
- antialias
- 'backspace' no longer supports number values. Instead:
  - for `backspace=0` set `backspace=` (empty)
  - for `backspace=1` set `backspace=indent,eol`
  - for `backspace=2` set `backspace=indent,eol,start` (default behavior in Nvim)
  - for `backspace=3` set `backspace=indent,eol,nostop`
- 'balloondelay' 'bdlay'
- 'balooneval' 'beval' 'noballooneval' 'nobeval'
- 'balloonexpr' 'bexpr'
- bioskey (MS-DOS)
- conskey (MS-DOS)
- 'cp' 'nocompatible' 'nocp' 'compatible' (Nvim is always "nocompatible".)
- 'cpoptions' (gjpkHw<*- and all POSIX flags were removed)
- 'cryptmethod' 'cm' 'key' (Vim encryption implementation)
- cscopepathcomp
- cscopeprg
- cscopequickfix

TUI: t_xx termcap-options t_AB t_Sb t_vb t_SI

- Nvim does not have special t_XX options nor <t_XX> keycodes to configure terminal capabilities. Instead Nvim treats the terminal as any other UI, e.g. 'guicursor' sets the terminal cursor style if possible. You can use $NVIM_TERMDEFS if you still need to override the builtin definitions.

termcap

- Nvim never uses the termcap database, only terminfo and builtin-terms.

xterm-8bit xterm-8-bit

- Xterm can be run in a mode where it uses true 8-bit CSI. Supporting this requires autodetection of whether the terminal is in UTF-8 mode or non-UTF-8 mode, as the 8-bit CSI character has to be written differently in each case. Vim issues a "request version" sequence to the terminal at startup and looks at how the terminal is sending CSI. Nvim does not issue such a sequence and always uses 7-bit control sequences.

Expression evaluation expr E15 eval eval.txt

Using expressions is introduced in chapter 41 of the user manual usr_41.txt.

1. Variables variables

1.1 Variable types

E712 E896 E897 E899 E908 E909
E928 E964 E966 E1023 E1098 E1174 E1175
E1203 E1206 E1210 E1211 E1212 E1219 E1220
E1222 E1225 E1226 E1238 E1250 E1252 E1256
E1265 E1297 E5010 E5050 E5060 E5070 E5071
E5299 E5300 E5401 E5420 E6000

There are seven types of variables:

Number Integer

Number	A 32 or 64 bit signed number. expr-number The number of bits is available in v:numbersize. Examples: -123 0x10 0177 0o177 0b1011
Float	A floating point number. floating-point-format Float Examples: 123.456 1.15e-6 -1.1e3
String	A NUL terminated string of 8-bit unsigned characters (bytes). expr-string Examples: "ab\txx\"--" 'x-z''a,c'
Funcref	A reference to a function Funcref. Example: function("strlen") It can be bound to a dictionary and arguments, it then works like a Partial. Example: function("Callback", [arg], myDict)
List	An ordered sequence of items, see List for details. Example: [1, 2, ['a', 'b']]
Dictionary	An associative, unordered array: Each entry has a key and a value. Dictionary Examples:

```
{"blue": "#0000ff", "red": "#ff0000"}
#{blue: "#0000ff", red: "#ff0000"}
```

Blob	Binary Large Object. Stores any sequence of bytes. See Blob for details. Example: 0zFF00ED015DAF 0z is an empty Blob.

The Number and String types are converted automatically, depending on how they are used.

Conversion from a Number to a String is by making the ASCII representation of the Number. Examples:

Number 123 --> String "123"
Number 0 --> String "0"
Number -1 --> String "-1"

octal

Conversion from a String to a Number is done by converting the first digits to a number. Hexadecimal "0xf9", Octal "017" or "0o17", and Binary "0b10" numbers are recognized. If the String doesn't start with digits, the result is zero. Examples:

String "456" --> Number 456
String "6bar" --> Number 6
String "foo" --> Number 0
String "0xf1" --> Number 241
String "0100" --> Number 64
String "0o100" --> Number 64
String "0b101" --> Number 5
String "-8" --> Number -8
String "+8" --> Number 0

To force conversion from String to Number, add zero to it:

```
:echo "0100" + 0
```

64

To avoid a leading zero to cause octal conversion, or for using a different base, use str2nr().

TRUE FALSE Boolean

For boolean operators Numbers are used. Zero is FALSE, non-zero is TRUE.
You can also use v:false and v:true.
When TRUE is returned from a function it is the Number one, FALSE is the number zero.

Note that in the command:

```
:if "foo"
:" NOT executed
```

"foo" is converted to 0, which means FALSE. If the string starts with a non-zero number it means TRUE:

```
:if "8foo"
:" executed
```

To test for a non-empty string, use empty():

```
:if !empty("foo")
```

falsy truthy

An expression can be used as a condition, ignoring the type and only using whether the value is "sort of true" or "sort of false". Falsy is:

```
        the number zero
        empty string, blob, list or dictionary
```

Other values are truthy. Examples:

```
        0       falsy
        1       truthy
        -1      truthy
        0.0     falsy
        0.1     truthy
        ''      falsy
        'x'     truthy
        []      falsy
        [0]     truthy
        {}      falsy
        #{x: 1} truthy
        0z      falsy
        0z00    truthy
```

non-zero-arg

Function arguments often behave slightly different from TRUE: If the argument is present and it evaluates to a non-zero Number, v:true or a non-empty String, then the value is considered to be TRUE.
Note that " " and "0" are also non-empty strings, thus considered to be TRUE.
A List, Dictionary or Float is not a Number or String, thus evaluate to FALSE.

E745 E728 E703 E729 E730 E731
E974 E975 E976

List, Dictionary, Funcref, and Blob types are not automatically converted.

E805 E806 E808

When mixing Number and Float the Number is converted to Float. Otherwise there is no automatic conversion of Float. You can use str2float() for String to Float, printf() for Float to String and float2nr() for Float to Number.

E362 E891 E892 E893 E894 E907

When expecting a Float a Number can also be used, but nothing else.

no-type-checking

You will not get an error if you try to change the type of a variable.

1.2 Function references

Funcref E695 E718 E1192

A Funcref variable is obtained with the function() function, the funcref() function or created with the lambda expression expr-lambda. It can be used in an expression in the place of a function name, before the parenthesis around the arguments, to invoke the function it refers to. Example:

```
:let Fn = function("MyFunc")
:echo Fn()
```

E704 E705 E707

A Funcref variable must start with a capital, "s:", "w:", "t:" or "b:". You can use "g:" but the following name must still start with a capital. You cannot have both a Funcref variable and a function with the same name.

A special case is defining a function and directly assigning its Funcref to a Dictionary entry. Example:

```
:function dict.init() dict
:   let self.val = 0
:endfunction
```

The key of the Dictionary can start with a lower case letter. The actual function name is not used here. Also see numbered-function.

A Funcref can also be used with the :call command:

```
:call Fn()
:call dict.init()
```

The name of the referenced function can be obtained with string().

```
:let func = string(Fn)
```

You can use call() to invoke a Funcref and use a list variable for the arguments:

```
:let r = call(Fn, mylist)
```

Partial

A Funcref optionally binds a Dictionary and/or arguments. This is also called
a Partial. This is created by passing the Dictionary and/or arguments to
function() or funcref(). When calling the function the Dictionary and/or
arguments will be passed to the function. Example:

```
let Cb = function('Callback', ['foo'], myDict)
call Cb('bar')
```

This will invoke the function as if using:

```
call myDict.Callback('foo', 'bar')
```

Note that binding a function to a Dictionary also happens when the function is
a member of the Dictionary:

```
let myDict.myFunction = MyFunction
call myDict.myFunction()
```

Here MyFunction() will get myDict passed as "self". This happens when the
"myFunction" member is accessed. When assigning "myFunction" to otherDict
and calling it, it will be bound to otherDict:

```
let otherDict.myFunction = myDict.myFunction
call otherDict.myFunction()
```

Now "self" will be "otherDict". But when the dictionary was bound explicitly
this won't happen:

```
let myDict.myFunction = function(MyFunction, myDict)
let otherDict.myFunction = myDict.myFunction
call otherDict.myFunction()
```

Here "self" will be "myDict", because it was bound explicitly.

1.3 Lists

list List Lists E686

A List is an ordered sequence of items. An item can be of any type. Items
can be accessed by their index number. Items can be added and removed at any
position in the sequence.

List creation

E696 E697

A List is created with a comma-separated list of items in square brackets.
Examples:

```
:let mylist = [1, two, 3, "four"]
:let emptylist = []
```

An item can be any expression. Using a List for an item creates a
List of Lists:

```
:let nestlist = [[11, 12], [21, 22], [31, 32]]
```

An extra comma after the last item is ignored.

List index

list-index E684

An item in the List can be accessed by putting the index in square brackets
after the List. Indexes are zero-based, thus the first item has index zero.

```
:let item = mylist[0]           " get the first item: 1
:let item = mylist[2]           " get the third item: 3
```

When the resulting item is a list this can be repeated:

```
:let item = nestlist[0][1]      " get the first list, second item: 12
```

A negative index is counted from the end. Index -1 refers to the last item in
the List, -2 to the last but one item, etc.

```
:let last = mylist[-1]          " get the last item: "four"
```

To avoid an error for an invalid index use the get() function. When an item
is not available it returns zero or the default value you specify:

```
:echo get(mylist, idx)
:echo get(mylist, idx, "NONE")
```

List concatenation

list-concatenation

Two lists can be concatenated with the "+" operator:

```
:let longlist = mylist + [5, 6]
:let longlist = [5, 6] + mylist
```

To prepend or append an item, turn it into a list by putting [] around it.

A list can be concatenated with another one in-place using :let+= or extend():

```
:let mylist += [7, 8]
:call extend(mylist, [7, 8])
```

See list-modification below for more about changing a list in-place.

Sublist

sublist

A part of the List can be obtained by specifying the first and last index, separated by a colon in square brackets:

```
:let shortlist = mylist[2:-1]   " get List [3, "four"]
```

Omitting the first index is similar to zero. Omitting the last index is similar to -1.

```
:let endlist = mylist[2:]       " from item 2 to the end: [3, "four"]
:let shortlist = mylist[2:2]    " List with one item: [3]
:let otherlist = mylist[:]      " make a copy of the List
```

Notice that the last index is inclusive. If you prefer using an exclusive index use the slice() method.

If the first index is beyond the last item of the List or the second item is before the first item, the result is an empty list. There is no error message.

If the second index is equal to or greater than the length of the list the length minus one is used:

```
:let mylist = [0, 1, 2, 3]
:echo mylist[2:8]               " result: [2, 3]
```

NOTE: mylist[s:e] means using the variable "s:e" as index. Watch out for using a single letter variable before the ":". Insert a space when needed: mylist[s : e].

List identity

list-identity

When variable "aa" is a list and you assign it to another variable "bb", both variables refer to the same list. Thus changing the list "aa" will also change "bb":

```
:let aa = [1, 2, 3]
:let bb = aa
:call add(aa, 4)
:echo bb
```

```
        [1, 2, 3, 4]
```

Making a copy of a list is done with the copy() function. Using [:] also works, as explained above. This creates a shallow copy of the list: Changing a list item in the list will also change the item in the copied list:

```
:let aa = [[1, 'a'], 2, 3]
:let bb = copy(aa)
:call add(aa, 4)
:let aa[0][1] = 'aaa'
:echo aa
```

```
        [[1, aaa], 2, 3, 4]
```

```
:echo bb
```

```
        [[1, aaa], 2, 3]
```

To make a completely independent list use deepcopy(). This also makes a copy of the values in the list, recursively. Up to a hundred levels deep.

The operator "is" can be used to check if two variables refer to the same List. "isnot" does the opposite. In contrast "==" compares if two lists have the same value.

```
:let alist = [1, 2, 3]
:let blist = [1, 2, 3]
:echo alist is blist
```

```
0
```

```
:echo alist == blist
```

```
1
```

Note about comparing lists: Two lists are considered equal if they have the same length and all items compare equal, as with using "==". There is one exception: When comparing a number with a string they are considered different. There is no automatic type conversion, as with using "==" on variables. Example:

```
echo 4 == "4"
```

```
1
```

```
echo [4] == ["4"]
```

```
0
```

Thus comparing Lists is more strict than comparing numbers and strings. You can compare simple values this way too by putting them in a list:

```
:let a = 5
:let b = "5"
:echo a == b
```

```
1
```

```
:echo [a] == [b]
```

```
0
```

List unpack

To unpack the items in a list to individual variables, put the variables in square brackets, like list items:

```
:let [var1, var2] = mylist
```

When the number of variables does not match the number of items in the list this produces an error. To handle any extra items from the list append ";" and a variable name:

```
:let [var1, var2; rest] = mylist
```

This works like:

```
:let var1 = mylist[0]
:let var2 = mylist[1]
:let rest = mylist[2:]
```

Except that there is no error if there are only two items. "rest" will be an empty list then.

List modification

list-modification

To change a specific item of a list use :let this way:

```
:let list[4] = "four"
:let listlist[0][3] = item
```

To change part of a list you can specify the first and last item to be modified. The value must at least have the number of items in the range:

```
:let list[3:5] = [3, 4, 5]
```

To add items to a List in-place, you can use :let+= (list-concatenation):

```
:let listA = [1, 2]
:let listA += [3, 4]
```

When two variables refer to the same List, changing one List in-place will cause the referenced List to be changed in-place:

```
:let listA = [1, 2]
:let listB = listA
:let listB += [3, 4]
:echo listA
[1, 2, 3, 4]
```

Adding and removing items from a list is done with functions. Here are a few examples:

```
:call insert(list, 'a')         " prepend item 'a'
:call insert(list, 'a', 3)      " insert item 'a' before list[3]
:call add(list, "new")          " append String item
:call add(list, [1, 2])         " append a List as one new item
:call extend(list, [1, 2])      " extend the list with two more items
:let i = remove(list, 3)        " remove item 3
:unlet list[3]                  " idem
:let l = remove(list, 3, -1)    " remove items 3 to last item
:unlet list[3 : ]               " idem
:call filter(list, 'v:val !~ "x"')  " remove items with an 'x'
```

Changing the order of items in a list:

```
:call sort(list)                " sort a list alphabetically
:call reverse(list)             " reverse the order of items
:call uniq(sort(list))          " sort and remove duplicates
```

For loop

The :for loop executes commands for each item in a List, String or Blob.
A variable is set to each item in sequence. Example with a List:

```
:for item in mylist
:   call Doit(item)
:endfor
```

This works like:

```
:let index = 0
:while index < len(mylist)
:   let item = mylist[index]
:   :call Doit(item)
:   let index = index + 1
:endwhile
```

If all you want to do is modify each item in the list then the map()
function will be a simpler method than a for loop.

Just like the :let command, :for also accepts a list of variables. This
requires the argument to be a List of Lists.

```
:for [lnum, col] in [[1, 3], [2, 8], [3, 0]]
:   call Doit(lnum, col)
:endfor
```

This works like a :let command is done for each list item. Again, the types
must remain the same to avoid an error.

It is also possible to put remaining items in a List variable:

```
:for [i, j; rest] in listlist
:   call Doit(i, j)
:   if !empty(rest)
:      echo "remainder: " .. string(rest)
:   endif
:endfor
```

For a Blob one byte at a time is used.

For a String one character, including any composing characters, is used as a
String. Example:

```
for c in text
  echo 'This character is ' .. c
endfor
```

List functions

E714

Functions that are useful with a List:

```
:let r = call(funcname, list)   " call a function with an argument list
:if empty(list)                 " check if list is empty
:let l = len(list)              " number of items in list
:let big = max(list)            " maximum value in list
:let small = min(list)          " minimum value in list
:let xs = count(list, 'x')      " count nr of times 'x' appears in list
:let i = index(list, 'x')       " index of first 'x' in list
:let lines = getline(1, 10)     " get ten text lines from buffer
:call append('$', lines)        " append text lines in buffer
:let list = split("a b c")      " create list from items in a string
:let string = join(list, ', ')  " create string from list items
:let s = string(list)           " String representation of list
:call map(list, '">> " .. v:val')  " prepend ">> " to each item
```

Don't forget that a combination of features can make things simple. For example, to add up all the numbers in a list:

```
:exe 'let sum = ' .. join(nrlist, '+')
```

1.4 Dictionaries

Dict dict Dictionaries Dictionary

A Dictionary is an associative array: Each entry has a key and a value. The entry can be located with the key. The entries are stored without a specific ordering.

Dictionary creation

E720 E721 E722 E723

A Dictionary is created with a comma-separated list of entries in curly braces. Each entry has a key and a value, separated by a colon. Each key can only appear once. Examples:

```
:let mydict = {1: 'one', 2: 'two', 3: 'three'}
:let emptydict = {}
```

E713 E716 E717

A key is always a String. You can use a Number, it will be converted to a String automatically. Thus the String '4' and the number 4 will find the same entry. Note that the String '04' and the Number 04 are different, since the Number will be converted to the String '4', leading zeros are dropped. The empty string can also be used as a key.

literal-Dict #{}

To avoid having to put quotes around every key the #{} form can be used. This does require the key to consist only of ASCII letters, digits, '-' and '_'. Example:

```
:let mydict = #{zero: 0, one_key: 1, two-key: 2, 333: 3}
```

Note that 333 here is the string "333". Empty keys are not possible with #{}.

A value can be any expression. Using a Dictionary for a value creates a nested Dictionary:

```
:let nestdict = {1: {11: 'a', 12: 'b'}, 2: {21: 'c'}}
```

An extra comma after the last entry is ignored.

Accessing entries

The normal way to access an entry is by putting the key in square brackets:

```
:let val = mydict["one"]
:let mydict["four"] = 4
```

You can add new entries to an existing Dictionary this way, unlike Lists.

For keys that consist entirely of letters, digits and underscore the following form can be used expr-entry:

```
:let val = mydict.one
:let mydict.four = 4
```

Since an entry can be any type, also a List and a Dictionary, the indexing and key lookup can be repeated:

```
:echo dict.key[idx].key
```

Dictionary to List conversion

You may want to loop over the entries in a dictionary. For this you need to turn the Dictionary into a List and pass it to :for.

Most often you want to loop over the keys, using the keys() function:

```
:for key in keys(mydict)
:   echo key .. ': ' .. mydict[key]
:endfor
```

The List of keys is unsorted. You may want to sort them first:

```
:for key in sort(keys(mydict))
```

To loop over the values use the values() function:

```
:for v in values(mydict)
:   echo "value: " .. v
:endfor
```

If you want both the key and the value use the items() function. It returns

a List in which each item is a List with two items, the key and the value:

```
:for [key, value] in items(mydict)
:   echo key .. ': ' .. value
:endfor
```

Dictionary identity

dict-identity

Just like Lists you need to use copy() and deepcopy() to make a copy of a Dictionary. Otherwise, assignment results in referring to the same Dictionary:

```
:let onedict = {'a': 1, 'b': 2}
:let adict = onedict
:let adict['a'] = 11
:echo onedict['a']
11
```

Two Dictionaries compare equal if all the key-value pairs compare equal. For more info see list-identity.

Dictionary modification

dict-modification

To change an already existing entry of a Dictionary, or to add a new entry, use :let this way:

```
:let dict[4] = "four"
:let dict['one'] = item
```

Removing an entry from a Dictionary is done with remove() or :unlet. Three ways to remove the entry with key "aaa" from dict:

```
:let i = remove(dict, 'aaa')
:unlet dict.aaa
:unlet dict['aaa']
```

Merging a Dictionary with another is done with extend():

```
:call extend(adict, bdict)
```

This extends adict with all entries from bdict. Duplicate keys cause entries in adict to be overwritten. An optional third argument can change this. Note that the order of entries in a Dictionary is irrelevant, thus don't expect ":echo adict" to show the items from bdict after the older entries in adict.

Weeding out entries from a Dictionary can be done with filter():

```
:call filter(dict, 'v:val =~ "x"')
```

This removes all entries from "dict" with a value not matching 'x'. This can also be used to remove all entries:

```
call filter(dict, 0)
```

Dictionary function

Dictionary-function self E725 E862

When a function is defined with the "dict" attribute it can be used in a special way with a dictionary. Example:

```
:function Mylen() dict
:   return len(self.data)
:endfunction
:let mydict = {'data': [0, 1, 2, 3], 'len': function("Mylen")}
:echo mydict.len()
```

This is like a method in object oriented programming. The entry in the Dictionary is a Funcref. The local variable "self" refers to the dictionary the function was invoked from.

It is also possible to add a function without the "dict" attribute as a Funcref to a Dictionary, but the "self" variable is not available then.

numbered-function anonymous-function

To avoid the extra name for the function it can be defined and directly assigned to a Dictionary in this way:

```
:let mydict = {'data': [0, 1, 2, 3]}
:function mydict.len()
:   return len(self.data)
:endfunction
:echo mydict.len()
```

The function will then get a number and the value of dict.len is a Funcref
that references this function. The function can only be used through a
Funcref. It will automatically be deleted when there is no Funcref
remaining that refers to it.

It is not necessary to use the "dict" attribute for a numbered function.

If you get an error for a numbered function, you can find out what it is with
a trick. Assuming the function is 42, the command is:

```
:function g:42
```

Functions for Dictionaries

E715

Functions that can be used with a Dictionary:

```
:if has_key(dict, 'foo')        " TRUE if dict has entry with key "foo"
:if empty(dict)                 " TRUE if dict is empty
:let l = len(dict)              " number of items in dict
:let big = max(dict)            " maximum value in dict
:let small = min(dict)          " minimum value in dict
:let xs = count(dict, 'x')      " count nr of times 'x' appears in dict
:let s = string(dict)           " String representation of dict
:call map(dict, '">> " .. v:val')  " prepend ">> " to each item
```

1.5 Blobs

blob Blob Blobs E978

A Blob is a binary object. It can be used to read an image from a file and
send it over a channel, for example.

A Blob mostly behaves like a List of numbers, where each number has the
value of an 8-bit byte, from 0 to 255.

Blob creation

A Blob can be created with a blob-literal:

```
:let b = 0zFF00ED015DAF
```

Dots can be inserted between bytes (pair of hex characters) for readability,
they don't change the value:

```
:let b = 0zFF00.ED01.5DAF
```

A blob can be read from a file with readfile() passing the {type} argument
set to "B", for example:

```
:let b = readfile('image.png', 'B')
```

Blob index

blob-index E979

A byte in the Blob can be accessed by putting the index in square brackets
after the Blob. Indexes are zero-based, thus the first byte has index zero.

```
:let myblob = 0z00112233
:let byte = myblob[0]           " get the first byte: 0x00
:let byte = myblob[2]           " get the third byte: 0x22
```

A negative index is counted from the end. Index -1 refers to the last byte in
the Blob, -2 to the last but one byte, etc.

```
:let last = myblob[-1]          " get the last byte: 0x33
```

To avoid an error for an invalid index use the get() function. When an item
is not available it returns -1 or the default value you specify:

```
:echo get(myblob, idx)
:echo get(myblob, idx, 999)
```

Blob iteration

The :for loop executes commands for each byte of a Blob. The loop variable is
set to each byte in the Blob. Example:

```
:for byte in 0z112233
:   call Doit(byte)
:endfor
```

This calls Doit() with 0x11, 0x22 and 0x33.

Blob concatenation

blob-concatenation

Two blobs can be concatenated with the "+" operator:

```
:let longblob = myblob + 0z4455
:let longblob = 0z4455 + myblob
```

A blob can be concatenated with another one in-place using :let+=:

```
:let myblob += 0z6677
```

See blob-modification below for more about changing a blob in-place.

Part of a blob

A part of the Blob can be obtained by specifying the first and last index,
separated by a colon in square brackets:

```
:let myblob = 0z00112233
:let shortblob = myblob[1:2]    " get 0z1122
:let shortblob = myblob[2:-1]   " get 0z2233
```

Omitting the first index is similar to zero. Omitting the last index is
similar to -1.

```
:let endblob = myblob[2:]       " from item 2 to the end: 0z2233
:let shortblob = myblob[2:2]    " Blob with one byte: 0z22
:let otherblob = myblob[:]      " make a copy of the Blob
```

If the first index is beyond the last byte of the Blob or the second index is
before the first index, the result is an empty Blob. There is no error
message.

If the second index is equal to or greater than the length of the Blob the
length minus one is used:

```
:echo myblob[2:8]               " result: 0z2233
```

Blob modification

blob-modification

To change a specific byte of a blob use :let this way:

```
:let blob[4] = 0x44
```

When the index is just one beyond the end of the Blob, it is appended. Any
higher index is an error.

To change a sequence of bytes the [:] notation can be used:

```
let blob[1:3] = 0z445566
```

The length of the replaced bytes must be exactly the same as the value
provided. E972

To change part of a blob you can specify the first and last byte to be
modified. The value must have the same number of bytes in the range:

```
:let blob[3:5] = 0z334455
```

To add items to a Blob in-place, you can use :let+= (blob-concatenation):

```
:let blobA = 0z1122
:let blobA += 0z3344
```

When two variables refer to the same Blob, changing one Blob in-place will
cause the referenced Blob to be changed in-place:

```
:let blobA = 0z1122
:let blobB = blobA
:let blobB += 0z3344
:echo blobA
0z11223344
```

You can also use the functions add(), remove() and insert().

Blob identity

Blobs can be compared for equality:

```
if blob == 0z001122
```

And for equal identity:

```
if blob is otherblob
```

blob-identity E977

When variable "aa" is a Blob and you assign it to another variable "bb", both
variables refer to the same Blob. Then the "is" operator returns true.

When making a copy using [:] or copy() the values are the same, but the identity is different:

```
:let blob = 0z112233
:let blob2 = blob
:echo blob == blob2
```

```
1
```

```
:echo blob is blob2
```

```
1
```

```
:let blob3 = blob[:]
:echo blob == blob3
```

```
1
```

```
:echo blob is blob3
```

```
0
```

Making a copy of a Blob is done with the copy() function. Using [:] also works, as explained above.

1.6 More about variables

more-variables

If you need to know the type of a variable or expression, use the type() function.

When the '!' flag is included in the 'shada' option, global variables that start with an uppercase letter, and don't contain a lowercase letter, are stored in the shada file shada-file.

When the 'sessionoptions' option contains "global", global variables that start with an uppercase letter and contain at least one lowercase letter are stored in the session file session-file.

variable name	can be stored where
my_var_6	not
My_Var_6	session file
MY_VAR_6	shada file

It's possible to form a variable name with curly braces, see curly-braces-names.

2. Expression syntax

expression-syntax

Expression syntax summary, from least to most significant:

```
expr1   expr2
        expr2 ? expr1 : expr1   if-then-else

expr2   expr3
        expr3 || expr3 ...      logical OR

expr3   expr4
        expr4 && expr4 ...      logical AND

expr4   expr5
        expr5 == expr5          equal
        expr5 != expr5          not equal
        expr5 >  expr5          greater than
        expr5 >= expr5          greater than or equal
        expr5 <  expr5          smaller than
        expr5 <= expr5          smaller than or equal
        expr5 =~ expr5          regexp matches
        expr5 !~ expr5          regexp doesn't match

        expr5 ==? expr5         equal, ignoring case
        expr5 ==# expr5         equal, match case
        etc.                    As above, append ? for ignoring case, # for
                                matching case

        expr5 is expr5          same List, Dictionary or Blob instance
        expr5 isnot expr5       different List, Dictionary or Blob
                                instance

expr5   expr6
        expr6 +  expr6 ...      number addition, list or blob concatenation
        expr6 -  expr6 ...      number subtraction
        expr6 .  expr6 ...      string concatenation
        expr6 .. expr6 ...      string concatenation

expr6   expr7
        expr7 *  expr7 ...      number multiplication
        expr7 /  expr7 ...      number division
        expr7 %  expr7 ...      number modulo

expr7   expr8
        ! expr7                 logical NOT
```

- expr7 unary minus

+ expr7 unary plus

expr8	expr9	
	expr8[expr1]	byte of a String or item of a List
	expr8[expr1 : expr1]	substring of a String or sublist of a List
	expr8.name	entry in a Dictionary
	expr8(expr1, ...)	function call with Funcref variable
	expr8->name(expr1, ...)	method call
expr9	number	number constant
	"string"	string constant, backslash is special
	'string'	string constant, ' is doubled
	[expr1, ...]	List
	{expr1: expr1, ...}	Dictionary
	#{key: expr1, ...}	Dictionary
	&option	option value
	(expr1)	nested expression
	variable	internal variable
	va{ria}ble	internal variable with curly braces
	$VAR	environment variable
	@r	contents of register "r"
	function(expr1, ...)	function call
	func{ti}on(expr1, ...)	function call with curly braces
	{args -> expr1}	lambda expression

"..." indicates that the operations in this level can be concatenated.
Example:

```
&nu || &list && &shell == "csh"
```

All expressions within one level are parsed from left to right.

Expression nesting is limited to 1000 levels deep (300 when build with MSVC)
to avoid running out of stack and crashing. E1169

expr1 — expr1 ternary falsy-operator ?? E109

The ternary operator: expr2 ? expr1 : expr1
The falsy operator: expr2 ?? expr1

Ternary operator

The expression before the '?' is evaluated to a number. If it evaluates to
TRUE, the result is the value of the expression between the '?' and ':',
otherwise the result is the value of the expression after the ':'.
Example:

```
:echo lnum == 1 ? "top" : lnum
```

Since the first expression is an "expr2", it cannot contain another ?:. The
other two expressions can, thus allow for recursive use of ?:.
Example:

```
:echo lnum == 1 ? "top" : lnum == 1000 ? "last" : lnum
```

To keep this readable, using line-continuation is suggested:

```
:echo lnum == 1
:\      ? "top"
:\      : lnum == 1000
:\              ? "last"
:\              : lnum
```

You should always put a space before the ':', otherwise it can be mistaken for
use in a variable such as "a:1".

Falsy operator

This is also known as the "null coalescing operator", but that's too
complicated, thus we just call it the falsy operator.

The expression before the '??' is evaluated. If it evaluates to
truthy, this is used as the result. Otherwise the expression after the '??'
is evaluated and used as the result. This is most useful to have a default
value for an expression that may result in zero or empty:

```
echo theList ?? 'list is empty'
echo GetName() ?? 'unknown'
```

These are similar, but not equal:

```
expr2 ?? expr1
expr2 ? expr2 : expr1
```

In the second line "expr2" is evaluated twice.

expr2 and expr3 — expr2 expr3

expr3 || expr3 ..   logical OR — expr-barbar

expr4 && expr4 ..   logical AND — expr-&&

The "||" and "&&" operators take one argument on each side. The arguments are (converted to) Numbers. The result is:

input	output		
n1 n2 n1 || n2 n1 && n2			
FALSE	FALSE	FALSE	FALSE
FALSE	TRUE	TRUE	FALSE
TRUE	FALSE	TRUE	FALSE
TRUE	TRUE	TRUE	TRUE

The operators can be concatenated, for example:

```
&nu || &list && &shell == "csh"
```

Note that "&&" takes precedence over "||", so this has the meaning of:

```
&nu || (&list && &shell == "csh")
```

Once the result is known, the expression "short-circuits", that is, further arguments are not evaluated. This is like what happens in C. For example:

```
let a = 1
echo a || b
```

This is valid even if there is no variable called "b" because "a" is TRUE, so the result must be TRUE. Similarly below:

```
echo exists("b") && b == "yes"
```

This is valid whether "b" has been defined or not. The second clause will only be evaluated if "b" has been defined.

expr4 **expr4**

expr5 {cmp} expr5

Compare two expr5 expressions, resulting in a 0 if it evaluates to false, or 1 if it evaluates to true.

expr-== expr-!= expr-> expr->=

expr-< expr-<= expr-=~ expr-!~
expr-==# expr-!=# expr-># expr->=#
expr-<# expr-<=# expr-=~# expr-!~#
expr-==? expr-!=? expr->? expr->=?
expr-<? expr-<=? expr-=~? expr-!~?
expr-is expr-isnot expr-is# expr-isnot#
expr-is? expr-isnot?

use 'ignorecase'	match case	ignore case	
equal	==	==#	==?
not equal	!=	!=#	!=?
greater than	>	>#	>?
greater than or equal	>=	>=#	>=?
smaller than	<	<#	<?
smaller than or equal	<=	<=#	<=?
regexp matches	=~	=~#	=~?
regexp doesn't match	!~	!~#	!~?
same instance	is	is#	is?
different instance	isnot	isnot#	isnot?

Examples:
"abc" ==# "Abc" evaluates to 0
"abc" ==? "Abc" evaluates to 1
"abc" == "Abc" evaluates to 1 if 'ignorecase' is set, 0 otherwise

E691 E692

A List can only be compared with a List and only "equal", "not equal", "is" and "isnot" can be used. This compares the values of the list, recursively. Ignoring case means case is ignored when comparing item values.

E735 E736

A Dictionary can only be compared with a Dictionary and only "equal", "not equal", "is" and "isnot" can be used. This compares the key/values of the Dictionary recursively. Ignoring case means case is ignored when comparing item values.

E694

A Funcref can only be compared with a Funcref and only "equal", "not equal", "is" and "isnot" can be used. Case is never ignored. Whether arguments or a Dictionary are bound (with a partial) matters. The Dictionaries must also be equal (or the same, in case of "is") and the arguments must be equal (or the same).

To compare Funcrefs to see if they refer to the same function, ignoring bound Dictionary and arguments, use get() to get the function name:

```
if get(Part1, 'name') == get(Part2, 'name')
   " Part1 and Part2 refer to the same function
```

Using "is" or "isnot" with a List, Dictionary or Blob checks whether
the expressions are referring to the same List, Dictionary or Blob
instance. A copy of a List is different from the original List. When
using "is" without a List, Dictionary or Blob, it is equivalent to
using "equal", using "isnot" is equivalent to using "not equal". Except that
a different type means the values are different:

```
echo 4 == '4'
1
echo 4 is '4'
0
echo 0 is []
0
```

"is#"/"isnot#" and "is?"/"isnot?" can be used to match and ignore case.

When comparing a String with a Number, the String is converted to a Number,
and the comparison is done on Numbers. This means that:

```
echo 0 == 'x'
1
```

because 'x' converted to a Number is zero. However:

```
echo [0] == ['x']
0
```

Inside a List or Dictionary this conversion is not used.

When comparing two Strings, this is done with strcmp() or stricmp(). This
results in the mathematical difference (comparing byte values), not
necessarily the alphabetical difference in the local language.

When using the operators with a trailing '#', or the short version and
'ignorecase' is off, the comparing is done with strcmp(): case matters.

When using the operators with a trailing '?', or the short version and
'ignorecase' is set, the comparing is done with stricmp(): case is ignored.

'smartcase' is not used.

The "=~" and "!~" operators match the lefthand argument with the righthand
argument, which is used as a pattern. See pattern for what a pattern is.
This matching is always done like 'magic' was set and 'cpoptions' is empty, no
matter what the actual value of 'magic' or 'cpoptions' is. This makes scripts
portable. To avoid backslashes in the regexp pattern to be doubled, use a
single-quote string, see literal-string.
Since a string is considered to be a single line, a multi-line pattern
(containing \n, backslash-n) will not match. However, a literal NL character
can be matched like an ordinary character. Examples:
```
        "foo\nbar" =~ "\n"      evaluates to 1
        "foo\nbar" =~ "\\n"     evaluates to 0
```

expr5 and expr6 **expr5** **expr6**

expr6 + expr6   Number addition, List or Blob concatenation   expr-+
expr6 - expr6   Number subtraction   expr--

expr6 . expr6   String concatenation   expr-.

expr6 .. expr6 String concatenation   expr-..

For Lists only "+" is possible and then both expr6 must be a list. The
result is a new list with the two lists Concatenated.

For String concatenation ".." is preferred, since "." is ambiguous, it is also
used for Dict member access and floating point numbers.

expr7 * expr7 Number multiplication   expr-star

expr7 / expr7 Number division   expr-/

expr7 % expr7 Number modulo   expr-%

For all, except "." and "..", Strings are converted to Numbers.
For bitwise operators see and(), or() and xor().

Note the difference between "+" and ".":
```
        "123" + "456" = 579
        "123" . "456" = "123456"
```

Since '.' has the same precedence as '+' and '-', you need to read:

```
1 . 90 + 90.0
```

As:

```
(1 . 90) + 90.0
```

That works, since the String "190" is automatically converted to the Number
190, which can be added to the Float 90.0. However:

```
1 . 90 * 90.0
```

Should be read as:

```
1 . (90 * 90.0)
```

Since '.' has lower precedence than "*". This does NOT work, since this
attempts to concatenate a Float and a String.

When dividing a Number by zero the result depends on the value:
```
  0 / 0  = -0x80000000  (like NaN for Float)
 >0 / 0  =  0x7fffffff  (like positive infinity)
 <0 / 0  = -0x7fffffff  (like negative infinity)
(before Vim 7.2 it was always 0x7fffffff)
```

When 64-bit Number support is enabled:
```
  0 / 0  = -0x8000000000000000  (like NaN for Float)
 >0 / 0  =  0x7fffffffffffffff  (like positive infinity)
 <0 / 0  = -0x7fffffffffffffff  (like negative infinity)
```

When the righthand side of '%' is zero, the result is 0.

None of these work for Funcrefs.

. and % do not work for Float. E804

expr7 expr7

! expr7 logical NOT expr-!

- expr7 unary minus expr-unary--

+ expr7 unary plus expr-unary-+

For '!' TRUE becomes FALSE, FALSE becomes TRUE (one).
For '-' the sign of the number is changed.
For '+' the number is unchanged. **Note:** "++" has no effect.

A String will be converted to a Number first.

These three can be repeated and mixed. Examples:
```
        !-1         == 0
        !!8         == 1
        --9         == 9
```

expr8 expr8

This expression is either expr9 or a sequence of the alternatives below,
in any order. E.g., these are all possible:
```
        expr8[expr1].name
        expr8.name[expr1]
        expr8(expr1, ...)[expr1].name
        expr8->(expr1, ...)[expr1]
```
Evaluation is always from left to right.

expr8[expr1] item of String or List expr-[] E111 subscript

In legacy Vim script:
If expr8 is a Number or String this results in a String that contains the
expr1'th single byte from expr8. expr8 is used as a String (a number is
automatically converted to a String), expr1 as a Number. This doesn't
recognize multibyte encodings, see byteidx() for an alternative, or use
split() to turn the string into a list of characters. Example, to get the
byte under the cursor:

```
:let c = getline(".")[col(".") - 1]
```

Index zero gives the first byte. This is like it works in C. Careful:
text column numbers start with one! Example, to get the byte under the
cursor:

```
:let c = getline(".")[col(".") - 1]
```

Index zero gives the first byte. Careful: text column numbers start with one!

If the length of the String is less than the index, the result is an empty
String. A negative index always results in an empty string (reason: backward
compatibility). Use [-1:] to get the last byte.

If expr8 is a List then it results the item at index expr1. See list-index
for possible index values. If the index is out of range this results in an
error. Example:

```
:let item = mylist[-1]          " get last item
```

Generally, if a List index is equal to or higher than the length of the List, or more negative than the length of the List, this results in an error.

expr8[expr1a : expr1b] substring or sublist expr-[:] substring

If expr8 is a String this results in the substring with the bytes or characters from expr1a to and including expr1b. expr8 is used as a String, expr1a and expr1b are used as a Number.

In legacy Vim script the indexes are byte indexes. This doesn't recognize multibyte encodings, see byteidx() for computing the indexes. If expr8 is a Number it is first converted to a String.

The item at index expr1b is included, it is inclusive. For an exclusive index use the slice() function.

If expr1a is omitted zero is used. If expr1b is omitted the length of the string minus one is used.

A negative number can be used to measure from the end of the string. -1 is the last character, -2 the last but one, etc.

If an index goes out of range for the string characters are omitted. If expr1b is smaller than expr1a the result is an empty string.

Examples:

```
:let c = name[-1:]              " last byte of a string
:let c = name[0:-1]             " the whole string
:let c = name[-2:-2]            " last but one byte of a string
:let s = line(".")[4:]          " from the fifth byte to the end
:let s = s[:-3]                 " remove last two bytes
```

slice

If expr8 is a List this results in a new List with the items indicated by the indexes expr1a and expr1b. This works like with a String, as explained just above. Also see sublist below. Examples:

```
:let l = mylist[:3]             " first four items
:let l = mylist[4:4]            " List with one item
:let l = mylist[:]              " shallow copy of a List
```

If expr8 is a Blob this results in a new Blob with the bytes in the indexes expr1a and expr1b, inclusive. Examples:

```
:let b = 0zDEADBEEF
:let bs = b[1:2]                " 0zADBE
:let bs = b[]                   " copy of 0zDEADBEEF
```

Using expr8[expr1] or expr8[expr1a : expr1b] on a Funcref results in an error.

Watch out for confusion between a namespace and a variable followed by a colon for a sublist:

```
mylist[n:]     " uses variable n
mylist[s:]     " uses namespace s:, error!
```

expr8.name entry in a Dictionary expr-entry

If expr8 is a Dictionary and it is followed by a dot, then the following name will be used as a key in the Dictionary. This is just like: expr8[name].

The name must consist of alphanumeric characters, just like a variable name, but it may start with a number. Curly braces cannot be used.

There must not be white space before or after the dot.

Examples:

```
:let dict = {"one": 1, 2: "two"}
:echo dict.one          " shows "1"
:echo dict.2            " shows "two"
:echo dict .2           " error because of space before the dot
```

Note that the dot is also used for String concatenation. To avoid confusion always put spaces around the dot for String concatenation.

expr8(expr1, ...) Funcref function call E1085

When expr8 is a Funcref type variable, invoke the function it refers to.

expr8->name([args]) method call method ->
expr8->{lambda}([args])

E260 E276

For methods that are also available as global functions this is the same as:

```
name(expr8 [, args])
```

There can also be methods specifically for the type of "expr8".

This allows for chaining, passing the value that one method returns to the
next method:

```
mylist->filter(filterexpr)->map(mapexpr)->sort()->join()
```

Example of using a lambda:

```
GetPercentage()->{x -> x * 100}()->printf('%d%%')
```

When using -> the expr7 operators will be applied first, thus:

```
-1.234->string()
```

Is equivalent to:

```
(-1.234)->string()
```

And NOT:

```
-(1.234->string())
```

E274

"->name(" must not contain white space. There can be white space before the
"->" and after the "(", thus you can split the lines like this:

```
mylist
\ ->filter(filterexpr)
\ ->map(mapexpr)
\ ->sort()
\ ->join()
```

When using the lambda form there must be no white space between the } and the

(.

expr9

number

number number constant expr-number

0x hex-number 0o octal-number 0b binary-number

Integer numbers can be written in multiple forms:

{N}	decimal
0x{N} or 0X{N}	hexadecimal
0o{N} or 0O{N}	octal
0{N}	octal
0b{N} or 0B{N}	binary

{N} is a sequence of decimal digits (0-9), hexadecimal digits (0-9, a-f and
A-F), octal digits (0-7) or binary digits (0 or 1).

A leading "+" or "-" is not part of an integer literal. E.g., -123 is an
expression, the unary operator expr-unary-- applied to the number 123.

Examples:

```
0xDEAD
57005
0b1101111010101101
0o157255
```

floating-point-format

Floating point numbers can be written in two forms:

```
{N}.{M}
{N}.{M}[eE][-+]{exp}
```

{N} and {M} are sequences of decimal digits Both {N} and {M} must be present.
{exp} is the exponent, power of 10.
Only a decimal point is accepted, not a comma. No matter what the current
locale is.

A leading "+" or "-" is not part of a floating point literal. E.g., -1.0e-3
is an expression, the unary operator expr-unary-- applied to the float 1.0e-3.
The "-" in the exponent is part of the literal.

Examples:

```
123.456
0.0001
55.0
0.123
1.234e03
1.0E-6
3.1416e+88
```

These are INVALID:

```
3.              empty {M}
```

```
        1e40            missing .{M}
```

Rationale:
Before floating point was introduced, the text "123.456" was interpreted as the two numbers "123" and "456", both converted to a string and concatenated, resulting in the string "123456". Since this was considered pointless, and we could not find it intentionally being used in Vim scripts, this backwards incompatibility was accepted in favor of being able to use the normal notation for floating point numbers.

float-pi float-e

A few useful values to copy&paste:

```
:let pi = 3.14159265359
:let e  = 2.71828182846
```

Or, if you don't want to write them in as floating-point literals, you can also use functions, like the following:

```
:let pi = acos(-1.0)
:let e  = exp(1.0)
```

floating-point-precision

The precision and range of floating points numbers depends on what "double" means in the library Vim was compiled with. There is no way to change this at runtime.

The default for displaying a Float is to use 6 decimal places, like using printf("%g", f). You can select something else when using the printf() function. Example:

```
:echo printf('%.15e', atan(1))
```

```
        7.853981633974483e-01
```

string

string String expr-string E114

```
"string"                string constant
```

expr-quote

Note that double quotes are used.

A string constant accepts these special characters:

```
\...    three-digit octal number (e.g., "\316")
\..     two-digit octal number (must be followed by non-digit)
\.      one-digit octal number (must be followed by non-digit)
\x..    byte specified with two hex numbers (e.g., "\x1f")
\x.     byte specified with one hex number (must be followed by non-hex char)
\X..    same as \x..
\X.     same as \x.
\u....  character specified with up to 4 hex numbers, stored as UTF-8
        (e.g., "\u02a4")
\U....  same as \u but allows up to 8 hex numbers.
\b      backspace <BS>
\e      escape <Esc>
\f      formfeed 0x0C
\n      newline <NL>
\r      return <CR>
\t      tab <Tab>
\\      backslash
\"      double quote
\<xxx>  Special key named "xxx".  e.g. "\<C-W>" for CTRL-W.  This is for use
        in mappings, the 0x80 byte is escaped.
        To use the double quote character it must be escaped: "<M-\">".
        Don't use <Char-xxxx> to get a UTF-8 character, use \uxxxx as
        mentioned above.
\<*xxx> Like \<xxx> but prepends a modifier instead of including it in the
        character.  E.g. "\<C-w>" is one character 0x17 while "\<*C-w>" is
        four bytes: 3 for the CTRL modifier and then character "W".
```

Note that "\xff" is stored as the byte 255, which may be invalid in some encodings. Use "\u00ff" to store character 255 correctly as UTF-8.

Note that "\000" and "\x00" force the end of the string.

blob-literal

blob-literal E973

Hexadecimal starting with 0z or 0Z, with an arbitrary number of bytes.
The sequence must be an even number of hex characters. Example:

```
:let b = 0zFF00ED015DAF
```

literal-string

literal-string E115

```
'string'                string constant
```

expr-'

Note that single quotes are used.

This string is taken as it is. No backslashes are removed or have a special meaning. The only exception is that two quotes stand for one quote.

Single quoted strings are useful for patterns, so that backslashes do not need to be doubled. These two commands are equivalent:

```
if a =~ "\\s*"
if a =~ '\s*'
```

interpolated-string

$quote **interpolated-string**

```
$"string"               interpolated string constant                    expr-$quote

$'string'               interpolated literal string constant    expr-$'
```

Interpolated strings are an extension of the string and literal-string, allowing the inclusion of Vim script expressions (see expr1). Any expression returning a value can be enclosed between curly braces. The value is converted to a string. All the text and results of the expressions are concatenated to make a new string.

E1278 E1279

To include an opening brace '{' or closing brace '}' in the string content double it. For double quoted strings using a backslash also works. A single closing brace '}' will result in an error.

Examples:

```
let your_name = input("What's your name? ")
```

What's your name? Peter

```
echo
echo $"Hello, {your_name}!"
```

Hello, Peter!

```
echo $"The square root of {{9}} is {sqrt(9)}"
```

The square root of {9} is 3.0

string-offset-encoding

A string consists of multiple characters. UTF-8 uses one byte for ASCII characters, two bytes for other latin characters and more bytes for other characters.

A string offset can count characters or bytes. Other programs may use UTF-16 encoding (16-bit words) and an offset of UTF-16 words. Some functions use byte offsets, usually for UTF-8 encoding. Other functions use character offsets, in which case the encoding doesn't matter.

The different offsets for the string "a©😊" are below:

```
  UTF-8 offsets:
      [0]: 61, [1]: C2, [2]: A9, [3]: F0, [4]: 9F, [5]: 98, [6]: 8A
  UTF-16 offsets:
      [0]: 0061, [1]: 00A9, [2]: D83D, [3]: DE0A
  UTF-32 (character) offsets:
      [0]: 00000061, [1]: 000000A9, [2]: 0001F60A
```

You can use the "g8" and "ga" commands on a character to see the decimal/hex/octal values.

The functions byteidx(), utf16idx() and charidx() can be used to convert between these indices. The functions strlen(), strutf16len() and strcharlen() return the number of bytes, UTF-16 code units and characters in a string respectively.

option

expr-option **E112** **E113**

```
&option                 option value, local value if possible
&g:option               global option value
&l:option               local option value
```

Examples:

```
echo "tabstop is " .. &tabstop
if &expandtab
```

Any option name can be used here. See options. When using the local value and there is no buffer-local or window-local value, the global value is used anyway.

register

expr-register **@r**

```
@r                      contents of register 'r'
```

The result is the contents of the named register, as a single string. Newlines are inserted where required. To get the contents of the unnamed register use @" or @@. See registers for an explanation of the available registers.

When using the '=' register you get the expression itself, not what it evaluates to. Use eval() to evaluate it.

```
nesting                                                 expr-nesting E110
-------
(expr1)                 nested expression
```

environment variable

expr-env

$VAR environment variable

The String value of any environment variable. When it is not defined, the result is an empty string.

The functions getenv() and setenv() can also be used and work for environment variables with non-alphanumeric names.
The function environ() can be used to get a Dict with all environment variables.

expr-env-expand

Note that there is a difference between using $VAR directly and using expand("$VAR"). Using it directly will only expand environment variables that are known inside the current Vim session. Using expand() will first try using the environment variables known inside the current Vim session. If that fails, a shell will be used to expand the variable. This can be slow, but it does expand all variables that the shell knows about. Example:

```
:echo $shell
:echo expand("$shell")
```

The first one probably doesn't echo anything, the second echoes the $shell variable (if your shell supports it).

internal variable

expr-variable

variable internal variable
See below internal-variables.

function call

expr-function E116 E118 E119 E120

function(expr1, ...) function call
See below functions.

lambda expression

expr-lambda lambda

{args -> expr1} lambda expression E451

A lambda expression creates a new unnamed function which returns the result of evaluating expr1. Lambda expressions differ from user-functions in the following ways:

1. The body of the lambda expression is an expr1 and not a sequence of Ex commands.
2. The prefix "a:" should not be used for arguments. E.g.:

```
:let F = {arg1, arg2 -> arg1 - arg2}
:echo F(5, 2)
```

```
3
```

The arguments are optional. Example:

```
:let F = {-> 'error function'}
:echo F('ignored')
```

```
error function
```

closure

Lambda expressions can access outer scope variables and arguments. This is often called a closure. Example where "i" and "a:arg" are used in a lambda while they already exist in the function scope. They remain valid even after the function returns:

```
:function Foo(arg)
:  let i = 3
:  return {x -> x + i - a:arg}
:endfunction
:let Bar = Foo(4)
:echo Bar(6)
```

```
5
```

Note that the variables must exist in the outer scope before the lambda is defined for this to work. See also :func-closure.

Lambda and closure support can be checked with:

```
if has('lambda')
```

Examples for using a lambda expression with sort(), map() and filter():

```
:echo map([1, 2, 3], {idx, val -> val + 1})
```

```
[2, 3, 4]
```

```
:echo sort([3,7,2,1,4], {a, b -> a - b})
```

```
        [1, 2, 3, 4, 7]
```

The lambda expression is also useful for jobs and timers:

```
:let timer = timer_start(500,
                \ {-> execute("echo 'Handler called'", "")},
                \ {'repeat': 3})
```

```
        Handler called
        Handler called
        Handler called
```

Note that it is possible to cause memory to be used and not freed if the
closure is referenced by the context it depends on:

```
function Function()
   let x = 0
   let F = {-> x}
 endfunction
```

The closure uses "x" from the function scope, and "F" in that same scope
refers to the closure. This cycle results in the memory not being freed.
Recommendation: don't do this.

Notice how execute() is used to execute an Ex command. That's ugly though.

Lambda expressions have internal names like '<lambda>42'. If you get an error
for a lambda expression, you can find what it is with the following command:

```
:function <lambda>42
```

See also: numbered-function

3. Internal variable internal-variables E461

An internal variable name can be made up of letters, digits and '_'. But it
cannot start with a digit. It's also possible to use curly braces, see
curly-braces-names.

An internal variable is created with the ":let" command :let.
An internal variable is explicitly destroyed with the ":unlet" command
:unlet.
Using a name that is not an internal variable or refers to a variable that has
been destroyed results in an error.

variable-scope

There are several name spaces for variables. Which one is to be used is
specified by what is prepended:

(nothing)		In a function: local to a function; otherwise: global
buffer-variable	b:	Local to the current buffer.
window-variable	w:	Local to the current window.
tabpage-variable	t:	Local to the current tab page.
global-variable	g:	Global.
local-variable	l:	Local to a function.
script-variable	s:	Local to a :sourced Vim script.
function-argument	a:	Function argument (only inside a function).
vim-variable	v:	Global, predefined by Vim.

The scope name by itself can be used as a Dictionary. For example, to
delete all script-local variables:

```
:for k in keys(s:)
:    unlet s:[k]
:endfor
```

buffer-variable b:var b:

A variable name that is preceded with "b:" is local to the current buffer.
Thus you can have several "b:foo" variables, one for each buffer.
This kind of variable is deleted when the buffer is wiped out or deleted with
:bdelete.

One local buffer variable is predefined:

b:changedtick changetick

b:changedtick The total number of changes to the current buffer. It is
incremented for each change. An undo command is also a change
in this case. Resetting 'modified' when writing the buffer is
also counted.
This can be used to perform an action only when the buffer has
changed. Example:

```
:if my_changedtick != b:changedtick
:       let my_changedtick = b:changedtick
:       call My_Update()
:endif
```

You cannot change or delete the b:changedtick variable.

window-variable w:var w:

A variable name that is preceded with "w:" is local to the current window. It
is deleted when the window is closed.

tabpage-variable t:var t:
A variable name that is preceded with "t:" is local to the current tab page,
It is deleted when the tab page is closed.

global-variable g:var g:
Inside functions global variables are accessed with "g:". Omitting this will
access a variable local to a function. But "g:" can also be used in any other
place if you like.

local-variable l:var l:
Inside functions local variables are accessed without prepending anything.
But you can also prepend "l:" if you like. However, without prepending "l:"
you may run into reserved variable names. For example "count". By itself it
refers to "v:count". Using "l:count" you can have a local variable with the
same name.

script-variable s:var
In a Vim script variables starting with "s:" can be used. They cannot be
accessed from outside of the scripts, thus are local to the script.

They can be used in:
- commands executed while the script is sourced
- functions defined in the script
- autocommands defined in the script
- functions and autocommands defined in functions and autocommands which were
  defined in the script (recursively)
- user defined commands defined in the script

Thus not in:
- other scripts sourced from this one
- mappings
- menus
- etc.

Script variables can be used to avoid conflicts with global variable names.
Take this example:

```
let s:counter = 0
function MyCounter()
  let s:counter = s:counter + 1
  echo s:counter
endfunction
command Tick call MyCounter()
```

You can now invoke "Tick" from any script, and the "s:counter" variable in
that script will not be changed, only the "s:counter" in the script where
"Tick" was defined is used.

Another example that does the same:

```
let s:counter = 0
command Tick let s:counter = s:counter + 1 | echo s:counter
```

When calling a function and invoking a user-defined command, the context for
script variables is set to the script where the function or command was
defined.

The script variables are also available when a function is defined inside a
function that is defined in a script. Example:

```
let s:counter = 0
function StartCounting(incr)
  if a:incr
    function MyCounter()
      let s:counter = s:counter + 1
    endfunction
  else
    function MyCounter()
      let s:counter = s:counter - 1
    endfunction
  endif
endfunction
```

This defines the MyCounter() function either for counting up or counting down

when calling StartCounting(). It doesn't matter from where StartCounting() is called, the s:counter variable will be accessible in MyCounter().

When the same script is sourced again it will use the same script variables. They will remain valid as long as Vim is running. This can be used to maintain a counter:

```
if !exists("s:counter")
  let s:counter = 1
  echo "script executed for the first time"
else
  let s:counter = s:counter + 1
  echo "script executed " .. s:counter .. " times now"
endif
```

Note that this means that filetype plugins don't get a different set of script variables for each buffer. Use local buffer variables instead b:var.

PREDEFINED VIM VARIABLES vim-variable

E963

The alphabetic list of all builtin variables and details are in a separate help file: vvars.

4. Builtin Functions vim-function functions

The Vimscript subsystem (referred to as "eval" internally) provides builtin functions. Scripts can also define user-functions.

See function-list to browse functions by topic.

The alphabetic list of all builtin functions and details are in a separate help file: vimscript-functions.

5. Defining functions user-function

New functions can be defined. These can be called just like builtin functions. The function takes arguments, executes a sequence of Ex commands and can return a value.

You can find most information about defining functions in userfunc.txt.

6. Curly braces names curly-braces-names

In most places where you can use a variable, you can use a "curly braces name" variable. This is a regular variable name with one or more expressions wrapped in braces {} like this:

```
my_{adjective}_variable
```

When Vim encounters this, it evaluates the expression inside the braces, puts that in place of the expression, and re-interprets the whole as a variable name. So in the above example, if the variable "adjective" was set to "noisy", then the reference would be to "my_noisy_variable", whereas if "adjective" was set to "quiet", then it would be to "my_quiet_variable".

One application for this is to create a set of variables governed by an option value. For example, the statement

```
echo my_{&background}_message
```

would output the contents of "my_dark_message" or "my_light_message" depending on the current value of 'background'.

You can use multiple brace pairs:

```
echo my_{adverb}_{adjective}_message
```

..or even nest them:

```
echo my_{ad{end_of_word}}_message
```

where "end_of_word" is either "verb" or "jective".

However, the expression inside the braces must evaluate to a valid single variable name, e.g. this is invalid:

```
:let foo='a + b'
:echo c{foo}d
```

.. since the result of expansion is "ca + bd", which is not a variable name.

curly-braces-function-names

You can call and define functions by an evaluated name in a similar way. Example:

```
:let func_end='whizz'
:call my_func_{func_end}(parameter)
```

This would call the function "my_func_whizz(parameter)".

This does NOT work:

```
:let i = 3
:let @{i} = ''  " error
:echo @{i}      " error
```

7. Commands

expression-commands

:let {var-name} = {expr1} :let E18
Set internal variable {var-name} to the result of the expression {expr1}. The variable will get the type from the {expr}. If {var-name} didn't exist yet, it is created.

:let {var-name}[{idx}] = {expr1} E689

Set a list item to the result of the expression {expr1}. {var-name} must refer to a list and {idx} must be a valid index in that list. For nested list the index can be repeated.
This cannot be used to add an item to a List.
This cannot be used to set a byte in a String. You can do that like this:

```
:let var = var[0:2] .. 'X' .. var[4:]
```

When {var-name} is a Blob then {idx} can be the length of the blob, in which case one byte is appended.

E711 E719
:let {var-name}[{idx1}:{idx2}] = {expr1} E708 E709 E710
Set a sequence of items in a List to the result of the expression {expr1}, which must be a list with the correct number of items.
{idx1} can be omitted, zero is used instead.
{idx2} can be omitted, meaning the end of the list.
When the selected range of items is partly past the end of the list, items will be added.

:let+= :let-= :letstar=
:let/= :let%= :let.= :let..= E734
:let {var} += {expr1} Like ":let {var} = {var} + {expr1}".
:let {var} -= {expr1} Like ":let {var} = {var} - {expr1}".
:let {var} *= {expr1} Like ":let {var} = {var} * {expr1}".
:let {var} /= {expr1} Like ":let {var} = {var} / {expr1}".
:let {var} %= {expr1} Like ":let {var} = {var} % {expr1}".
:let {var} .= {expr1} Like ":let {var} = {var} . {expr1}".
:let {var} ..= {expr1} Like ":let {var} = {var} .. {expr1}".
These fail if {var} was not set yet and when the type of {var} and {expr1} don't fit the operator.
+= modifies a List or a Blob in-place instead of creating a new one.

:let ${env-name} = {expr1} :let-environment :let-$
Set environment variable {env-name} to the result of the expression {expr1}. The type is always String.
:let ${env-name} .= {expr1}
:let ${env-name} ..= {expr1}
Append {expr1} to the environment variable {env-name}. If the environment variable didn't exist yet this works like "=".

:let @{reg-name} = {expr1} :let-register :let-@
Write the result of the expression {expr1} in register {reg-name}. {reg-name} must be a single letter, and must be the name of a writable register (see registers). "@@" can be used for the unnamed register, "@/" for the search pattern.
If the result of {expr1} ends in a <CR> or <NL>, the register will be linewise, otherwise it will be set to charwise.
This can be used to clear the last search pattern:

```
:let @/ = ""
```

This is different from searching for an empty string, that would match everywhere.

:let @{reg-name} .= {expr1}
:let @{reg-name} ..= {expr1}
Append {expr1} to register {reg-name}. If the register was empty it's like setting it to {expr1}.

:let &{option-name} = {expr1} :let-option :let-&
Set option {option-name} to the result of the

expression {expr1}. A String or Number value is
always converted to the type of the option.
For an option local to a window or buffer the effect
is just like using the :set command: both the local
value and the global value are changed.
Example:

```
:let &path = &path .. ',/usr/local/include'
```

:let &{option-name} .= {expr1}
:let &{option-name} ..= {expr1}
For a string option: Append {expr1} to the value.
Does not insert a comma like :set+=.

:let &{option-name} += {expr1}
:let &{option-name} -= {expr1}
For a number or boolean option: Add or subtract
{expr1}.

:let &l:{option-name} = {expr1}
:let &l:{option-name} += {expr1}
:let &l:{option-name} -= {expr1}
:let &l:{option-name} .= {expr1}
:let &l:{option-name} ..= {expr1}
Like above, but only set the local value of an option
(if there is one). Works like :setlocal.

:let &g:{option-name} = {expr1}
:let &g:{option-name} += {expr1}
:let &g:{option-name} -= {expr1}
:let &g:{option-name} .= {expr1}
:let &g:{option-name} ..= {expr1}
Like above, but only set the global value of an option
(if there is one). Works like :setglobal.

:let [{name1}, {name2}, ...] = {expr1} :let-unpack E687 E688
{expr1} must evaluate to a List. The first item in
the list is assigned to {name1}, the second item to
{name2}, etc.
The number of names must match the number of items in
the List.
Each name can be one of the items of the ":let"
command as mentioned above.
Example:

```
:let [s, item] = GetItem(s)
```

Detail: {expr1} is evaluated first, then the
assignments are done in sequence. This matters if
{name2} depends on {name1}. Example:

```
:let x = [0, 1]
:let i = 0
:let [i, x[i]] = [1, 2]
:echo x
```

The result is [0, 2].

:let [{name1}, {name2}, ...] += {expr1}
:let [{name1}, {name2}, ...] -= {expr1}
:let [{name1}, {name2}, ...] *= {expr1}
:let [{name1}, {name2}, ...] /= {expr1}
:let [{name1}, {name2}, ...] %= {expr1}
:let [{name1}, {name2}, ...] .= {expr1}
:let [{name1}, {name2}, ...] ..= {expr1}
Like above, but add, subtract, multiply, divide,
modulo, or append the value for each List item.

:let [{name}, ..., ; {lastname}] = {expr1} E452

Like :let-unpack above, but the List may have more
items than there are names. A list of the remaining
items is assigned to {lastname}. If there are no
remaining items {lastname} is set to an empty list.
Example:

```
:let [a, b; rest] = ["aval", "bval", 3, 4]
```

:let [{name}, ..., ; {lastname}] += {expr1}
:let [{name}, ..., ; {lastname}] -= {expr1}
:let [{name}, ..., ; {lastname}] .= {expr1}
:let [{name}, ..., ; {lastname}] ..= {expr1}
Like above, but add/subtract/append the value for each
List item.

:let=<< :let-heredoc
E990 E991 E172 E221 E1145
:let {var-name} =<< [trim] [eval] {endmarker}
text...
text...
{endmarker}
Set internal variable {var-name} to a List

containing the lines of text bounded by the string
{endmarker}.

If "eval" is not specified, then each line of text is
used as a literal-string, except that single quotes
does not need to be doubled.
If "eval" is specified, then any Vim expression in the
form {expr} is evaluated and the result replaces the
expression, like with interpolated-string.
Example where $HOME is expanded:

```
let lines =<< trim eval END
  some text
  See the file {$HOME}/.vimrc
  more text
END
```

There can be multiple Vim expressions in a single line
but an expression cannot span multiple lines. If any
expression evaluation fails, then the assignment
fails.

{endmarker} must not contain white space.
{endmarker} cannot start with a lower case character.
The last line should end only with the {endmarker}
string without any other character. Watch out for
white space after {endmarker}!

Without "trim" any white space characters in the lines
of text are preserved. If "trim" is specified before
{endmarker}, then indentation is stripped so you can
do:

```
let text =<< trim END
   if ok
     echo 'done'
   endif
END
```

Results in: ["if ok", " echo 'done'", "endif"]
The end marker must line up with "let" and the
indentation of the first line is removed from all the
text lines.
Specifically: all the leading indentation exactly
matching the leading indentation of the first
non-empty text line is stripped from the input lines.
All leading indentation exactly matching the leading
indentation before let is stripped from the line
containing {endmarker}. Note that the difference
between space and tab matters here.

If {var-name} didn't exist yet, it is created.
Cannot be followed by another command, but can be
followed by a comment.

To avoid line continuation to be applied, consider
adding 'C' to 'cpoptions':

```
set cpo+=C
let var =<< END
   \ leading backslash
END
set cpo-=C
```

Examples:

```
let var1 =<< END
Sample text 1
    Sample text 2
Sample text 3
END

let data =<< trim DATA
        1 2 3 4
        5 6 7 8
DATA

let code =<< trim eval CODE
   let v = {10 + 20}
   let h = "{$HOME}"
   let s = "{Str1()} abc {Str2()}"
   let n = {MyFunc(3, 4)}
CODE
```

E121

:let {var-name} ... List the value of variable {var-name}. Multiple
variable names may be given. Special names recognized
here: E738

  g: global variables
  b: local buffer variables

```
                        w:    local window variables
                        t:    local tab page variables
                        s:    script-local variables
                        l:    local function variables
                        v:    Vim variables.
```

:let List the values of all variables. The type of the variable is indicated before the value:

```
    <nothing>   String
        #       Number
        *       Funcref
```

:unl[et][!] {name} ... :unlet :unl E108 E795

Remove the internal variable {name}. Several variable names can be given, they are all removed. The name may also be a List or Dictionary item.
With [!] no error message is given for non-existing variables.
One or more items from a List can be removed:

```
:unlet list[3]    " remove fourth item
:unlet list[3:]   " remove fourth item to last
```

One item from a Dictionary can be removed at a time:

```
:unlet dict['two']
:unlet dict.two
```

This is especially useful to clean up used global variables and script-local variables (these are not deleted when the script ends). Function-local variables are automatically deleted when the function ends.

:unl[et] ${env-name} ... :unlet-environment :unlet-$

Remove environment variable {env-name}.
Can mix {name} and ${env-name} in one :unlet command.
No error message is given for a non-existing variable, also without !.
If the system does not support deleting an environment variable, it is made empty.

:cons :const

```
:cons[t] {var-name} = {expr1}
:cons[t] [{name1}, {name2}, ...] = {expr1}
:cons[t] [{name}, ..., ; {lastname}] = {expr1}
:cons[t] {var-name} =<< [trim] [eval] {endmarker}
text...
text...
{endmarker}
```

Similar to :let, but additionally lock the variable after setting the value. This is the same as locking the variable with :lockvar just after :let, thus:

```
:const x = 1
```

is equivalent to:

```
:let x = 1
:lockvar! x
```

This is useful if you want to make sure the variable is not modified. If the value is a List or Dictionary literal then the items also cannot be changed:

```
const ll = [1, 2, 3]
let ll[1] = 5  " Error!
```

Nested references are not locked:

```
let lvar = ['a']
const lconst = [0, lvar]
let lconst[0] = 2  " Error!
let lconst[1][0] = 'b'  " OK
```

E995

It is an error to specify an existing variable with :const.

```
:let x = 1
:const x = 1  " Error!
```

E996

Note that environment variables, option values and register values cannot be used here, since they cannot be locked.

:cons[t]
:cons[t] {var-name}

If no argument is given or only {var-name} is given, the behavior is the same as :let.

:lockv[ar][!] [depth] {name} ... :lockvar :lockv

Lock the internal variable {name}. Locking means that it can no longer be changed (until it is unlocked). A locked variable can be deleted:

```
:lockvar v
:let v = 'asdf'   " fails!
:unlet v          " works
```

E741 E940 E1122

If you try to change a locked variable you get an error message: "E741: Value is locked: {name}". If you try to lock or unlock a built-in variable you will get an error message "E940: Cannot lock or unlock variable {name}".

[depth] is relevant when locking a List or Dictionary. It specifies how deep the locking goes:

0	Lock the variable {name} but not its value.
1	Lock the List or Dictionary itself, cannot add or remove items, but can still change their values.
2	Also lock the values, cannot change the items. If an item is a List or Dictionary, cannot add or remove items, but can still change the values.
3	Like 2 but for the List / Dictionary in the List / Dictionary, one level deeper.

The default [depth] is 2, thus when {name} is a List or Dictionary the values cannot be changed.

Example with [depth] 0:

```
let mylist = [1, 2, 3]
lockvar 0 mylist
let mylist[0] = 77      " OK
call add(mylist, 4)     " OK
let mylist = [7, 8, 9]  " Error!
```

E743

For unlimited depth use [!] and omit [depth]. However, there is a maximum depth of 100 to catch loops.

Note that when two variables refer to the same List and you lock one of them, the List will also be locked when used through the other variable. Example:

```
:let l = [0, 1, 2, 3]
:let cl = l
:lockvar l
:let cl[1] = 99         " won't work!
```

You may want to make a copy of a list to avoid this. See deepcopy().

:unlo[ckvar][!] [depth] {name} ... :unlockvar :unlo

Unlock the internal variable {name}. Does the opposite of :lockvar.

No error is given if {name} does not exist.

:if {expr1} :if :end :endif :en E171 E579 E580
:en[dif]

Execute the commands until the next matching :else or :endif if {expr1} evaluates to non-zero. Although the short forms work, it is recommended to always use :endif to avoid confusion and to make auto-indenting work properly.

From Vim version 4.5 until 5.0, every Ex command in between the :if and :endif is ignored. These two commands were just to allow for future expansions in a backward compatible way. Nesting was allowed. Note that any :else or :elseif was ignored, the else part was not executed either.

You can use this to remain compatible with older versions:

```
:if version >= 500
:  version-5-specific-commands
:endif
```

The commands still need to be parsed to find the endif. Sometimes an older Vim has a problem with a new command. For example, :silent is recognized as

a :substitute command. In that case :execute can
avoid problems:

```
:if version >= 600
:  execute "silent 1,$delete"
:endif
```

NOTE: The :append and :insert commands don't work
properly in between :if and :endif.

:else :el E581 E583

:el[se] Execute the commands until the next matching :else
or :endif if they previously were not being
executed.

:elseif :elsei E582 E584

:elsei[f] {expr1} Short for :else :if, with the addition that there
is no extra :endif.

:while :endwhile :wh :endw
E170 E585 E588 E733

:wh[ile] {expr1}

:endw[hile] Repeat the commands between :while and :endwhile,
as long as {expr1} evaluates to non-zero.
When an error is detected from a command inside the
loop, execution continues after the endwhile.
Example:

```
:let lnum = 1
:while lnum <= line("$")
   :call FixLine(lnum)
   :let lnum = lnum + 1
:endwhile
```

NOTE: The :append and :insert commands don't work
properly inside a :while and :for loop.

:for E690 E732

:for {var} in {object}

:endfo :endfor

:endfo[r] Repeat the commands between :for and :endfor for
each item in {object}. {object} can be a List,
a Blob or a String.

Variable {var} is set to the value of each item.

When an error is detected for a command inside the
loop, execution continues after the endfor.
Changing {object} inside the loop affects what items
are used. Make a copy if this is unwanted:

```
:for item in copy(mylist)
```

When {object} is a List and not making a copy, Vim
stores a reference to the next item in the List
before executing the commands with the current item.
Thus the current item can be removed without effect.
Removing any later item means it will not be found.
Thus the following example works (an inefficient way
to make a List empty):

```
for item in mylist
   call remove(mylist, 0)
endfor
```

Note that reordering the List (e.g., with sort() or
reverse()) may have unexpected effects.

When {object} is a Blob, Vim always makes a copy to
iterate over. Unlike with List, modifying the
Blob does not affect the iteration.

When {object} is a String each item is a string with
one character, plus any combining characters.

:for [{var1}, {var2}, ...] in {listlist}
:endfo[r]

Like :for above, but each item in {listlist} must be
a list, of which each item is assigned to {var1},
{var2}, etc. Example:

```
:for [lnum, col] in [[1, 3], [2, 5], [3, 8]]
   :echo getline(lnum)[col]
:endfor
```

:continue :con E586

:con[tinue] When used inside a :while or :for loop, jumps back
to the start of the loop.

If it is used after a :try inside the loop but
before the matching :finally (if present), the
commands following the :finally up to the matching
:endtry are executed first. This process applies to
all nested :trys inside the loop. The outermost
:endtry then jumps back to the start of the loop.

:break :brea E587

:brea[k] When used inside a :while or :for loop, skips to

the command after the matching :endwhile or
:endfor.
If it is used after a :try inside the loop but
before the matching :finally (if present), the
commands following the :finally up to the matching
:endtry are executed first. This process applies to
all nested :trys inside the loop. The outermost
:endtry then jumps to the command after the loop.

:try :endt :endtry E600 E601 E602

:endt[ry] Change the error handling for the commands between
:try and :endtry including everything being
executed across :source commands, function calls,
or autocommand invocations.

When an error or interrupt is detected and there is
a :finally command following, execution continues
after the :finally. Otherwise, or when the
:endtry is reached thereafter, the next
(dynamically) surrounding :try is checked for
a corresponding :finally etc. Then the script
processing is terminated. Whether a function
definition has an "abort" argument does not matter.
Example:

```
try | call Unknown() | finally | echomsg "cleanup" | endtry
echomsg "not reached"
```

Moreover, an error or interrupt (dynamically) inside
:try and :endtry is converted to an exception. It
can be caught as if it were thrown by a :throw
command (see :catch). In this case, the script
processing is not terminated.

The value "Vim:Interrupt" is used for an interrupt
exception. An error in a Vim command is converted
to a value of the form "Vim({command}):{errmsg}",
other errors are converted to a value of the form
"Vim:{errmsg}". {command} is the full command name,
and {errmsg} is the message that is displayed if the
error exception is not caught, always beginning with
the error number.
Examples:

```
try | sleep 100 | catch /^Vim:Interrupt$/ | endtry
try | edit | catch /^Vim(edit):E\d\+/ | echo "error" | endtry
```

:cat :catch
E603 E604 E605 E654

:cat[ch] [/{pattern}/] The following commands until the next :catch,
:finally, or :endtry that belongs to the same
:try as the :catch are executed when an exception
matching {pattern} is being thrown and has not yet
been caught by a previous :catch. Otherwise, these
commands are skipped.
Pattern can start with "Vim({cmd})" to indicate an
exception that occurred when executing the Ex command
{cmd}. When {pattern} is omitted all errors are
caught. Examples:

```
:catch /^Vim:Interrupt$/         " catch interrupts (CTRL-C)
:catch /^Vim\%((\S\+)\)\=:E/     " catch all Vim errors
:catch /^Vim\%((\S\+)\)\=:/      " catch errors and interrupts
:catch /^Vim(write):/            " catch all errors in :write
:catch /^Vim(!):/                " catch all errors in :!
:catch /^Vim\%((\S\+)\)\=:E123:/ " catch error E123
:catch /my-exception/            " catch user exception
:catch /.*/                      " catch everything
:catch                           " same as /.*/
```

Another character can be used instead of / around the
{pattern}, so long as it does not have a special
meaning (e.g., '|' or '"') and doesn't occur inside
{pattern}.
Information about the exception is available in
v:exception. Also see throw-variables.
NOTE: It is not reliable to ":catch" the TEXT of
an error message because it may vary in different
locales.

:fina :finally E606 E607

:fina[lly] The following commands until the matching :endtry
are executed whenever the part between the matching
:try and the :finally is left: either by falling
through to the :finally or by a :continue,
:break, :finish, or :return, or by an error or
interrupt or exception (see :throw).

:th :throw E608

:th[row] {expr1} The {expr1} is evaluated and thrown as an exception.
If the :throw is used after a :try but before the
first corresponding :catch, commands are skipped

until the first :catch matching {expr1} is reached.
If there is no such :catch or if the :throw is
used after a :catch but before the :finally, the
commands following the :finally (if present) up to
the matching :endtry are executed. If the :throw
is after the :finally, commands up to the :endtry
are skipped. At the :endtry, this process applies
again for the next dynamically surrounding :try
(which may be found in a calling function or sourcing
script), until a matching :catch has been found.
If the exception is not caught, the command processing
is terminated.
Example:

```
:try | throw "oops" | catch /^oo/ | echo "caught" | endtry
```

Note that "catch" may need to be on a separate line
for when an error causes the parsing to skip the whole
line and not see the "|" that separates the commands.

:ec :echo

:ec[ho] {expr1} ... Echoes each {expr1}, with a space in between. The
first {expr1} starts on a new line.
Also see :comment.
Use "\n" to start a new line. Use "\r" to move the
cursor to the first column.
Uses the highlighting set by the :echohl command.
Cannot be followed by a comment.
Example:

```
:echo "the value of 'shell' is" &shell
```

:echo-redraw

A later redraw may make the message disappear again.
And since Vim mostly postpones redrawing until it's
finished with a sequence of commands this happens
quite often. To avoid that a command from before the
:echo causes a redraw afterwards (redraws are often
postponed until you type something), force a redraw
with the :redraw command. Example:

```
:new | redraw | echo "there is a new window"
```

:echo-self-refer

When printing nested containers echo prints second
occurrence of the self-referencing container using
"[...@level]" (self-referencing List) or
"{...@level}" (self-referencing Dict):

```
:let l = []
:call add(l, l)
:let l2 = []
:call add(l2, [l2])
:echo l l2
```

echoes "[[...@0]] [[[...@0]]]". Echoing "[l]" will
echo "[[[...@1]]]" because l first occurs at second
level.

:echon

:echon {expr1} ...   Echoes each {expr1}, without anything added. Also see
:comment.
Uses the highlighting set by the :echohl command.
Cannot be followed by a comment.
Example:

```
:echon "the value of 'shell' is " &shell
```

Note the difference between using :echo, which is a
Vim command, and :!echo, which is an external shell
command:

```
:!echo %               --> filename
```

The arguments of ":!" are expanded, see :_%.

```
:!echo "%"             --> filename or "filename"
```

Like the previous example. Whether you see the double
quotes or not depends on your 'shell'.

```
:echo %                --> nothing
```

The '%' is an illegal character in an expression.

```
:echo "%"              --> %
```

This just echoes the '%' character.

```
:echo expand("%")       --> filename
```

This calls the expand() function to expand the '%'.

:echoh :echohl

:echoh[l] {name} Use the highlight group {name} for the following :echo, :echon and :echomsg commands. Also used for the input() prompt. Example:

```
:echohl WarningMsg | echo "Don't panic!" | echohl None
```

Don't forget to set the group back to "None", otherwise all following echo's will be highlighted.

:echom :echomsg

:echom[sg] {expr1} ... Echo the expression(s) as a true message, saving the message in the message-history. Spaces are placed between the arguments as with the :echo command. But unprintable characters are displayed, not interpreted. The parsing works slightly different from :echo, more like :execute. All the expressions are first evaluated and concatenated before echoing anything. If expressions does not evaluate to a Number or String, string() is used to turn it into a string. Uses the highlighting set by the :echohl command. Example:

```
:echomsg "It's a Zizzer Zazzer Zuzz, as you can plainly see."
```

See :echo-redraw to avoid the message disappearing when the screen is redrawn.

:echoe :echoerr

:echoe[rr] {expr1} ... Echo the expression(s) as an error message, saving the message in the message-history. When used in a script or function the line number will be added. Spaces are placed between the arguments as with the :echomsg command. When used inside a try conditional, the message is raised as an error exception instead (see try-echoerr). Example:

```
:echoerr "This script just failed!"
```

If you just want a highlighted message use :echohl. And to get a beep:

```
:exe "normal \<Esc>"
```

:eval

:eval {expr} Evaluate {expr} and discard the result. Example:

```
:eval Getlist()->Filter()->append('$')
```

The expression is supposed to have a side effect, since the resulting value is not used. In the example the append() call appends the List with text to the buffer. This is similar to :call but works with any expression.

The command can be shortened to :ev or :eva, but these are hard to recognize and therefore not to be used.

The command cannot be followed by "|" and another command, since "|" is seen as part of the expression.

:exe :execute

:exe[cute] {expr1} ... Executes the string that results from the evaluation of {expr1} as an Ex command. Multiple arguments are concatenated, with a space in between. To avoid the extra space use the ".." operator to concatenate strings into one argument. {expr1} is used as the processed command, command line editing keys are not recognized. Cannot be followed by a comment. Examples:

```
:execute "buffer" nextbuf
:execute "normal" count .. "w"
```

":execute" can be used to append a command to commands that don't accept a '|'. Example:

```
:execute '!ls' | echo "theend"
```

":execute" is also a nice way to avoid having to type control characters in a Vim script for a ":normal" command:

```
:execute "normal ixxx\<Esc>"
```

This has an <Esc> character, see expr-string.

Be careful to correctly escape special characters in file names. The fnameescape() function can be used for Vim commands, shellescape() for :! commands. Examples:

```
:execute "e " .. fnameescape(filename)
:execute "!ls " .. shellescape(filename, 1)
```

Note: The executed string may be any command-line, but starting or ending "if", "while" and "for" does not always work, because when commands are skipped the ":execute" is not evaluated and Vim loses track of where blocks start and end. Also "break" and "continue" should not be inside ":execute". This example does not work, because the ":execute" is not evaluated and Vim does not see the "while", and gives an error for finding an ":endwhile":

```
:if 0
: execute 'while i > 5'
:  echo "test"
: endwhile
:endif
```

It is allowed to have a "while" or "if" command completely in the executed string:

```
:execute 'while i < 5 | echo i | let i = i + 1 | endwhile'
```

:exe-comment

":execute", ":echo" and ":echon" cannot be followed by a comment directly, because they see the '"' as the start of a string. But, you can use '|' followed by a comment. Example:

```
:echo "foo" | "this is a comment
```

8. Exception handling exception-handling

The Vim script language comprises an exception handling feature. This section explains how it can be used in a Vim script.

Exceptions may be raised by Vim on an error or on interrupt, see catch-errors and catch-interrupt. You can also explicitly throw an exception by using the ":throw" command, see throw-catch.

TRY CONDITIONALS try-conditionals

Exceptions can be caught or can cause cleanup code to be executed. You can use a try conditional to specify catch clauses (that catch exceptions) and/or a finally clause (to be executed for cleanup).
   A try conditional begins with a :try command and ends at the matching :endtry command. In between, you can use a :catch command to start a catch clause, or a :finally command to start a finally clause. There may be none or multiple catch clauses, but there is at most one finally clause, which must not be followed by any catch clauses. The lines before the catch clauses and the finally clause is called a try block.

```
:try
:       ...
:       ...                             TRY BLOCK
:       ...
:catch /{pattern}/
:       ...
:       ...                             CATCH CLAUSE
:       ...
:catch /{pattern}/
:       ...
:       ...                             CATCH CLAUSE
:       ...
:finally
:       ...
:       ...                             FINALLY CLAUSE
:       ...
:endtry
```

The try conditional allows to watch code for exceptions and to take the appropriate actions. Exceptions from the try block may be caught. Exceptions from the try block and also the catch clauses may cause cleanup actions.
   When no exception is thrown during execution of the try block, the control is transferred to the finally clause, if present. After its execution, the script continues with the line following the ":endtry".

When an exception occurs during execution of the try block, the remaining lines in the try block are skipped. The exception is matched against the patterns specified as arguments to the ":catch" commands. The catch clause after the first matching ":catch" is taken, other catch clauses are not executed. The catch clause ends when the next ":catch", ":finally", or ":endtry" command is reached - whatever is first. Then, the finally clause (if present) is executed. When the ":endtry" is reached, the script execution continues in the following line as usual.

When an exception that does not match any of the patterns specified by the ":catch" commands is thrown in the try block, the exception is not caught by that try conditional and none of the catch clauses is executed. Only the finally clause, if present, is taken. The exception pends during execution of the finally clause. It is resumed at the ":endtry", so that commands after the ":endtry" are not executed and the exception might be caught elsewhere, see try-nesting.

When during execution of a catch clause another exception is thrown, the remaining lines in that catch clause are not executed. The new exception is not matched against the patterns in any of the ":catch" commands of the same try conditional and none of its catch clauses is taken. If there is, however, a finally clause, it is executed, and the exception pends during its execution. The commands following the ":endtry" are not executed. The new exception might, however, be caught elsewhere, see try-nesting.

When during execution of the finally clause (if present) an exception is thrown, the remaining lines in the finally clause are skipped. If the finally clause has been taken because of an exception from the try block or one of the catch clauses, the original (pending) exception is discarded. The commands following the ":endtry" are not executed, and the exception from the finally clause is propagated and can be caught elsewhere, see try-nesting.

The finally clause is also executed, when a ":break" or ":continue" for a ":while" loop enclosing the complete try conditional is executed from the try block or a catch clause. Or when a ":return" or ":finish" is executed from the try block or a catch clause of a try conditional in a function or sourced script, respectively. The ":break", ":continue", ":return", or ":finish" pends during execution of the finally clause and is resumed when the ":endtry" is reached. It is, however, discarded when an exception is thrown from the finally clause.

When a ":break" or ":continue" for a ":while" loop enclosing the complete try conditional or when a ":return" or ":finish" is encountered in the finally clause, the rest of the finally clause is skipped, and the ":break", ":continue", ":return" or ":finish" is executed as usual. If the finally clause has been taken because of an exception or an earlier ":break", ":continue", ":return", or ":finish" from the try block or a catch clause, this pending exception or command is discarded.

For examples see throw-catch and try-finally.

NESTING OF TRY CONDITIONALS try-nesting

Try conditionals can be nested arbitrarily. That is, a complete try conditional can be put into the try block, a catch clause, or the finally clause of another try conditional. If the inner try conditional does not catch an exception thrown in its try block or throws a new exception from one of its catch clauses or its finally clause, the outer try conditional is checked according to the rules above. If the inner try conditional is in the try block of the outer try conditional, its catch clauses are checked, but otherwise only the finally clause is executed. It does not matter for nesting, whether the inner try conditional is directly contained in the outer one, or whether the outer one sources a script or calls a function containing the inner try conditional.

When none of the active try conditionals catches an exception, just their finally clauses are executed. Thereafter, the script processing terminates. An error message is displayed in case of an uncaught exception explicitly thrown by a ":throw" command. For uncaught error and interrupt exceptions implicitly raised by Vim, the error message(s) or interrupt message are shown as usual.

For examples see throw-catch.

EXAMINING EXCEPTION HANDLING CODE except-examine

Exception handling code can get tricky. If you are in doubt what happens, set 'verbose' to 13 or use the ":13verbose" command modifier when sourcing your script file. Then you see when an exception is thrown, discarded, caught, or finished. When using a verbosity level of at least 14, things pending in a finally clause are also shown. This information is also given in debug mode (see debug-scripts).

THROWING AND CATCHING EXCEPTIONS throw-catch

You can throw any number or string as an exception. Use the :throw command and pass the value to be thrown as argument:

```
:throw 4711
:throw "string"
```

throw-expression

You can also specify an expression argument. The expression is then evaluated first, and the result is thrown:

```
:throw 4705 + strlen("string")
:throw strpart("strings", 0, 6)
```

An exception might be thrown during evaluation of the argument of the ":throw"
command. Unless it is caught there, the expression evaluation is abandoned.
The ":throw" command then does not throw a new exception.
   Example:

```
:function! Foo(arg)
:  try
:    throw a:arg
:  catch /foo/
:  endtry
:  return 1
:endfunction
:
:function! Bar()
:  echo "in Bar"
:  return 4710
:endfunction
:
:throw Foo("arrgh") + Bar()
```

This throws "arrgh", and "in Bar" is not displayed since Bar() is not
executed.

```
:throw Foo("foo") + Bar()
```

however displays "in Bar" and throws 4711.

Any other command that takes an expression as argument might also be
abandoned by an (uncaught) exception during the expression evaluation. The
exception is then propagated to the caller of the command.
   Example:

```
:if Foo("arrgh")
:  echo "then"
:else
:  echo "else"
:endif
```

Here neither of "then" or "else" is displayed.

catch-order

Exceptions can be caught by a try conditional with one or more :catch
commands, see try-conditionals.   The values to be caught by each ":catch"
command can be specified as a pattern argument. The subsequent catch clause
gets executed when a matching exception is caught.
   Example:

```
:function! Foo(value)
:  try
:    throw a:value
:  catch /^\d\+$/
:    echo "Number thrown"
:  catch /.*/
:    echo "String thrown"
:  endtry
:endfunction
:
:call Foo(0x1267)
:call Foo('string')
```

The first call to Foo() displays "Number thrown", the second "String thrown".
An exception is matched against the ":catch" commands in the order they are
specified. Only the first match counts. So you should place the more
specific ":catch" first. The following order does not make sense:

```
:  catch /.*/
:    echo "String thrown"
:  catch /^\d\+$/
:    echo "Number thrown"
```

The first ":catch" here matches always, so that the second catch clause is
never taken.

throw-variables

If you catch an exception by a general pattern, you may access the exact value
in the variable v:exception:

```
:  catch /^\d\+$/
:    echo "Number thrown.  Value is" v:exception
```

You may also be interested where an exception was thrown. This is stored in
v:throwpoint. And you can obtain the stack trace from v:stacktrace.
Note that "v:exception", "v:stacktrace" and "v:throwpoint" are valid for the
exception most recently caught as long it is not finished.
   Example:

```
:function! Caught()
:  if v:exception != ""
:    echo 'Caught "' .. v:exception .. '" in ' .. v:throwpoint
:  else
:    echo 'Nothing caught'
:  endif
:endfunction
:
:function! Foo()
:  try
:    try
:      try
:        throw 4711
:      finally
:        call Caught()
:      endtry
:    catch /.*/
:      call Caught()
:      throw "oops"
:    endtry
:  catch /.*/
:    call Caught()
:  finally
:    call Caught()
:  endtry
:endfunction
:
:call Foo()
```

This displays

```
Nothing caught
Caught "4711" in function Foo, line 4
Caught "oops" in function Foo, line 10
Nothing caught
```

A practical example: The following command ":LineNumber" displays the line
number in the script or function where it has been used:

```
:function! LineNumber()
:    return substitute(v:throwpoint, '.*\D\(\d\+\).*', '\1', "")
:endfunction
:command! LineNumber try | throw "" | catch | echo LineNumber() | endtry
```

try-nested

An exception that is not caught by a try conditional can be caught by
a surrounding try conditional:

```
:try
:  try
:    throw "foo"
:  catch /foobar/
:    echo "foobar"
:  finally
:    echo "inner finally"
:  endtry
:catch /foo/
:  echo "foo"
:endtry
```

The inner try conditional does not catch the exception, just its finally
clause is executed. The exception is then caught by the outer try
conditional. The example displays "inner finally" and then "foo".

throw-from-catch

You can catch an exception and throw a new one to be caught elsewhere from the
catch clause:

```
:function! Foo()
:  throw "foo"
:endfunction
:
:function! Bar()
:  try
:    call Foo()
:  catch /foo/
:    echo "Caught foo, throw bar"
:    throw "bar"
:  endtry
:endfunction
:
:try
:  call Bar()
:catch /.*/
:  echo "Caught" v:exception
:endtry
```

This displays "Caught foo, throw bar" and then "Caught bar".

rethrow

There is no real rethrow in the Vim script language, but you may throw
"v:exception" instead:

```
:function! Bar()
:  try
:    call Foo()
:  catch /.*/
:    echo "Rethrow" v:exception
:    throw v:exception
:  endtry
:endfunction
```

try-echoerr

Note that this method cannot be used to "rethrow" Vim error or interrupt
exceptions, because it is not possible to fake Vim internal exceptions.
Trying so causes an error exception. You should throw your own exception
denoting the situation. If you want to cause a Vim error exception containing
the original error exception value, you can use the :echoerr command:

```
:try
:  try
:    asdf
:  catch /.*/
:    echoerr v:exception
:  endtry
:catch /.*/
:  echo v:exception
:endtry
```

This code displays

Vim(echoerr):Vim:E492: Not an editor command: asdf

CLEANUP CODE **try-finally**

Scripts often change global settings and restore them at their end. If the
user however interrupts the script by pressing CTRL-C, the settings remain in
an inconsistent state. The same may happen to you in the development phase of
a script when an error occurs or you explicitly throw an exception without
catching it. You can solve these problems by using a try conditional with
a finally clause for restoring the settings. Its execution is guaranteed on
normal control flow, on error, on an explicit ":throw", and on interrupt.
(Note that errors and interrupts from inside the try conditional are converted
to exceptions. When not caught, they terminate the script after the finally
clause has been executed.)
Example:

```
:try
:  let s:saved_ts = &ts
:  set ts=17
:
:  " Do the hard work here.
:
:finally
:  let &ts = s:saved_ts
:  unlet s:saved_ts
:endtry
```

This method should be used locally whenever a function or part of a script
changes global settings which need to be restored on failure or normal exit of
that function or script part.

break-finally

Cleanup code works also when the try block or a catch clause is left by
a ":continue", ":break", ":return", or ":finish".
   Example:

```
:let first = 1
:while 1
:  try
:    if first
:      echo "first"
:      let first = 0
:      continue
:    else
:      throw "second"
:    endif
:  catch /.*/
:    echo v:exception
:    break
:  finally
:    echo "cleanup"
:  endtry
:  echo "still in while"
:endwhile
:echo "end"
```

This displays "first", "cleanup", "second", "cleanup", and "end".

```
:function! Foo()
:  try
:    return 4711
:  finally
:    echo "cleanup\n"
:  endtry
:  echo "Foo still active"
:endfunction
:
:echo Foo() "returned by Foo"
```

This displays "cleanup" and "4711 returned by Foo". You don't need to add an
extra ":return" in the finally clause. (Above all, this would override the
return value.)

except-from-finally

Using either of ":continue", ":break", ":return", ":finish", or ":throw" in
a finally clause is possible, but not recommended since it abandons the
cleanup actions for the try conditional. But, of course, interrupt and error
exceptions might get raised from a finally clause.
   Example where an error in the finally clause stops an interrupt from
working correctly:

```
:try
:  try
:    echo "Press CTRL-C for interrupt"
:    while 1
:    endwhile
:  finally
:    unlet novar
:  endtry
:catch /novar/
:endtry
:echo "Script still running"
:sleep 1
```

If you need to put commands that could fail into a finally clause, you should
think about catching or ignoring the errors in these commands, see
catch-errors and ignore-errors.

CATCHING ERRORS **catch-errors**

If you want to catch specific errors, you just have to put the code to be
watched in a try block and add a catch clause for the error message. The
presence of the try conditional causes all errors to be converted to an
exception. No message is displayed and v:errmsg is not set then. To find
the right pattern for the ":catch" command, you have to know how the format of
the error exception is.
   Error exceptions have the following format:

```
Vim({cmdname}):{errmsg}
```

or

```
Vim:{errmsg}
```

{cmdname} is the name of the command that failed; the second form is used when
the command name is not known. {errmsg} is the error message usually produced

when the error occurs outside try conditionals. It always begins with
a capital "E", followed by a two or three-digit error number, a colon, and
a space.

Examples:

The command

```
:unlet novar
```

normally produces the error message

```
E108: No such variable: "novar"
```

which is converted inside try conditionals to an exception

```
Vim(unlet):E108: No such variable: "novar"
```

The command

```
:dwim
```

normally produces the error message

```
E492: Not an editor command: dwim
```

which is converted inside try conditionals to an exception

```
Vim:E492: Not an editor command: dwim
```

You can catch all ":unlet" errors by a

```
:catch /^Vim(unlet):/
```

or all errors for misspelled command names by a

```
:catch /^Vim:E492:/
```

Some error messages may be produced by different commands:

```
:function nofunc
```

and

```
:delfunction nofunc
```

both produce the error message

```
E128: Function name must start with a capital: nofunc
```

which is converted inside try conditionals to an exception

```
Vim(function):E128: Function name must start with a capital: nofunc
```

or

```
Vim(delfunction):E128: Function name must start with a capital: nofunc
```

respectively. You can catch the error by its number independently on the
command that caused it if you use the following pattern:

```
:catch /^Vim(\a\+):E128:/
```

Some commands like

```
:let x = novar
```

produce multiple error messages, here:

```
E121: Undefined variable: novar
E15: Invalid expression:  novar
```

Only the first is used for the exception value, since it is the most specific
one (see except-several-errors). So you can catch it by

```
:catch /^Vim(\a\+):E121:/
```

You can catch all errors related to the name "nofunc" by

```
:catch /\<nofunc\>/
```

You can catch all Vim errors in the ":write" and ":read" commands by

```
:catch /^Vim(\(write\|read\)):E\d\+:/
```

You can catch all Vim errors by the pattern

```
:catch /^Vim\((\a\+)\)\=:E\d\+:/
```

catch-text

NOTE: You should never catch the error message text itself:

```
:catch /No such variable/
```

only works in the English locale, but not when the user has selected
a different language by the :language command. It is however helpful to
cite the message text in a comment:

```
:catch /^Vim(\a\+):E108:/   " No such variable
```

IGNORING ERRORS

ignore-errors

You can ignore errors in a specific Vim command by catching them locally:

```
:try
:  write
:catch
:endtry
```

But you are strongly recommended NOT to use this simple form, since it could
catch more than you want. With the ":write" command, some autocommands could
be executed and cause errors not related to writing, for instance:

```
:au BufWritePre * unlet novar
```

There could even be such errors you are not responsible for as a script
writer: a user of your script might have defined such autocommands. You would
then hide the error from the user.
   It is much better to use

```
:try
:  write
:catch /^Vim(write):/
:endtry
```

which only catches real write errors. So catch only what you'd like to ignore
intentionally.

For a single command that does not cause execution of autocommands, you could
even suppress the conversion of errors to exceptions by the ":silent!"
command:

```
:silent! nunmap k
```

This works also when a try conditional is active.

CATCHING INTERRUPTS

catch-interrupt

When there are active try conditionals, an interrupt (CTRL-C) is converted to
the exception "Vim:Interrupt". You can catch it like every exception. The
script is not terminated, then.
   Example:

```
:function! TASK1()
:  sleep 10
:endfunction

:function! TASK2()
:  sleep 20
:endfunction

:while 1
:  let command = input("Type a command: ")
:  try
:    if command == ""
:      continue
:    elseif command == "END"
:      break
:    elseif command == "TASK1"
:      call TASK1()
:    elseif command == "TASK2"
:      call TASK2()
:    else
:      echo "\nIllegal command:" command
:      continue
:    endif
:  catch /^Vim:Interrupt$/
:    echo "\nCommand interrupted"
:    " Caught the interrupt.  Continue with next prompt.
:  endtry
:endwhile
```

You can interrupt a task here by pressing CTRL-C; the script then asks for
a new command. If you press CTRL-C at the prompt, the script is terminated.

For testing what happens when CTRL-C would be pressed on a specific line in
your script, use the debug mode and execute the >quit or >interrupt
command on that line. See debug-scripts.

CATCHING ALL **catch-all**

The commands

```
:catch /.*/
:catch //
:catch
```

catch everything, error exceptions, interrupt exceptions and exceptions
explicitly thrown by the :throw command. This is useful at the top level of
a script in order to catch unexpected things.
   Example:

```
:try
:
:  " do the hard work here
:
:catch /MyException/
:
:  " handle known problem
:
:catch /^Vim:Interrupt$/
:    echo "Script interrupted"
:catch /.*/
:  echo "Internal error (" .. v:exception .. ")"
:  echo " - occurred at " .. v:throwpoint
:endtry
:" end of script
```

Note: Catching all might catch more things than you want. Thus, you are
strongly encouraged to catch only for problems that you can really handle by
specifying a pattern argument to the ":catch".
   Example: Catching all could make it nearly impossible to interrupt a script
by pressing CTRL-C:

```
:while 1
:  try
:    sleep 1
:  catch
:  endtry
:endwhile
```

EXCEPTIONS AND AUTOCOMMANDS **except-autocmd**

Exceptions may be used during execution of autocommands. Example:

```
:autocmd User x try
:autocmd User x   throw "Oops!"
:autocmd User x catch
:autocmd User x   echo v:exception
:autocmd User x endtry
:autocmd User x throw "Arrgh!"
:autocmd User x echo "Should not be displayed"
:
:try
:  doautocmd User x
:catch
:  echo v:exception
:endtry
```

This displays "Oops!" and "Arrgh!".

except-autocmd-Pre

For some commands, autocommands get executed before the main action of the command takes place. If an exception is thrown and not caught in the sequence of autocommands, the sequence and the command that caused its execution are abandoned and the exception is propagated to the caller of the command.
Example:

```
:autocmd BufWritePre * throw "FAIL"
:autocmd BufWritePre * echo "Should not be displayed"
:
:try
:  write
:catch
:  echo "Caught:" v:exception "from" v:throwpoint
:endtry
```

Here, the ":write" command does not write the file currently being edited (as you can see by checking 'modified'), since the exception from the BufWritePre autocommand abandons the ":write". The exception is then caught and the script displays:

```
Caught: FAIL from BufWrite Auto commands for "*"
```

except-autocmd-Post

For some commands, autocommands get executed after the main action of the command has taken place. If this main action fails and the command is inside an active try conditional, the autocommands are skipped and an error exception is thrown that can be caught by the caller of the command.
Example:

```
:autocmd BufWritePost * echo "File successfully written!"
:
:try
:  write /i/m/p/o/s/s/i/b/l/e
:catch
:  echo v:exception
:endtry
```

This just displays:

```
Vim(write):E212: Can't open file for writing (/i/m/p/o/s/s/i/b/l/e)
```

If you really need to execute the autocommands even when the main action fails, trigger the event from the catch clause.
Example:

```
:autocmd BufWritePre  * set noreadonly
:autocmd BufWritePost * set readonly
:
:try
:  write /i/m/p/o/s/s/i/b/l/e
:catch
:  doautocmd BufWritePost /i/m/p/o/s/s/i/b/l/e
:endtry
```

You can also use ":silent!":

```
:let x = "ok"
:let v:errmsg = ""
:autocmd BufWritePost * if v:errmsg != ""
:autocmd BufWritePost *   let x = "after fail"
:autocmd BufWritePost * endif
:try
:  silent! write /i/m/p/o/s/s/i/b/l/e
:catch
:endtry
:echo x
```

This displays "after fail".

If the main action of the command does not fail, exceptions from the
autocommands will be catchable by the caller of the command:

```
:autocmd BufWritePost * throw ":-("
:autocmd BufWritePost * echo "Should not be displayed"
:
:try
:  write
:catch
:  echo v:exception
:endtry
```

except-autocmd-Cmd

For some commands, the normal action can be replaced by a sequence of
autocommands. Exceptions from that sequence will be catchable by the caller
of the command.
   Example: For the ":write" command, the caller cannot know whether the file
had actually been written when the exception occurred. You need to tell it in
some way.

```
:if !exists("cnt")
:  let cnt = 0
:
:  autocmd BufWriteCmd * if &modified
:  autocmd BufWriteCmd *   let cnt = cnt + 1
:  autocmd BufWriteCmd *   if cnt % 3 == 2
:  autocmd BufWriteCmd *     throw "BufWriteCmdError"
:  autocmd BufWriteCmd *   endif
:  autocmd BufWriteCmd *   write | set nomodified
:  autocmd BufWriteCmd *   if cnt % 3 == 0
:  autocmd BufWriteCmd *     throw "BufWriteCmdError"
:  autocmd BufWriteCmd *   endif
:  autocmd BufWriteCmd *   echo "File successfully written!"
:  autocmd BufWriteCmd * endif
:endif
:
:try
:       write
:catch /^BufWriteCmdError$/
:  if &modified
:    echo "Error on writing (file contents not changed)"
:  else
:    echo "Error after writing"
:  endif
:catch /^Vim(write):/
:    echo "Error on writing"
:endtry
```

When this script is sourced several times after making changes, it displays
first

```
File successfully written!
```

then

```
Error on writing (file contents not changed)
```

then

```
Error after writing
```

etc.

except-autocmd-ill

You cannot spread a try conditional over autocommands for different events.
The following code is ill-formed:

```
:autocmd BufWritePre  * try
:
:autocmd BufWritePost * catch
:autocmd BufWritePost *   echo v:exception
:autocmd BufWritePost * endtry
:
:write
```

EXCEPTION HIERARCHIES AND PARAMETERIZED EXCEPTIONS **except-hier-param**

Some programming languages allow to use hierarchies of exception classes or to
pass additional information with the object of an exception class. You can do
similar things in Vim.

In order to throw an exception from a hierarchy, just throw the complete class name with the components separated by a colon, for instance throw the string "EXCEPT:MATHERR:OVERFLOW" for an overflow in a mathematical library.
When you want to pass additional information with your exception class, add it in parentheses, for instance throw the string "EXCEPT:IO:WRITEERR(myfile)" for an error when writing "myfile".
With the appropriate patterns in the ":catch" command, you can catch for base classes or derived classes of your hierarchy. Additional information in parentheses can be cut out from v:exception with the ":substitute" command.
Example:

```
:function! CheckRange(a, func)
:  if a:a < 0
:    throw "EXCEPT:MATHERR:RANGE(" .. a:func .. ")"
:  endif
:endfunction
:
:function! Add(a, b)
:  call CheckRange(a:a, "Add")
:  call CheckRange(a:b, "Add")
:  let c = a:a + a:b
:  if c < 0
:    throw "EXCEPT:MATHERR:OVERFLOW"
:  endif
:  return c
:endfunction
:
:function! Div(a, b)
:  call CheckRange(a:a, "Div")
:  call CheckRange(a:b, "Div")
:  if (a:b == 0)
:    throw "EXCEPT:MATHERR:ZERODIV"
:  endif
:  return a:a / a:b
:endfunction
:
:function! Write(file)
:  try
:    execute "write" fnameescape(a:file)
:  catch /^Vim(write):/
:    throw "EXCEPT:IO(" .. getcwd() .. ", " .. a:file .. "):WRITEERR"
:  endtry
:endfunction
:
:try
:
:  " something with arithmetic and I/O
:
:catch /^EXCEPT:MATHERR:RANGE/
:  let function = substitute(v:exception, '.*(\(\a\+\)).*', '\1', "")
:  echo "Range error in" function
:
:catch /^EXCEPT:MATHERR/        " catches OVERFLOW and ZERODIV
:  echo "Math error"
:
:catch /^EXCEPT:IO/
:  let dir = substitute(v:exception, '.*(\(.\+\),\s*.\+).*', '\1', "")
:  let file = substitute(v:exception, '.*(.\+,\s*\(.\+\)).*', '\1', "")
:  if file !~ '^/'
:    let file = dir .. "/" .. file
:  endif
:  echo 'I/O error for "' .. file .. '"'
:
:catch /^EXCEPT/
:  echo "Unspecified error"
:
:endtry
```

The exceptions raised by Vim itself (on error or when pressing CTRL-C) use a flat hierarchy: they are all in the "Vim" class. You cannot throw yourself exceptions with the "Vim" prefix; they are reserved for Vim.
Vim error exceptions are parameterized with the name of the command that failed, if known. See catch-errors.

PECULIARITIES

except-compat

The exception handling concept requires that the command sequence causing the exception is aborted immediately and control is transferred to finally clauses and/or a catch clause.

In the Vim script language there are cases where scripts and functions continue after an error: in functions without the "abort" flag or in a command after ":silent!", control flow goes to the following line, and outside functions, control flow goes to the line following the outermost ":endwhile" or ":endif". On the other hand, errors should be catchable as exceptions (thus, requiring the immediate abortion).

This problem has been solved by converting errors to exceptions and using
immediate abortion (if not suppressed by ":silent!") only when a try
conditional is active. This is no restriction since an (error) exception can
be caught only from an active try conditional. If you want an immediate
termination without catching the error, just use a try conditional without
catch clause. (You can cause cleanup code being executed before termination
by specifying a finally clause.)

When no try conditional is active, the usual abortion and continuation
behavior is used instead of immediate abortion. This ensures compatibility of
scripts written for Vim 6.1 and earlier.

However, when sourcing an existing script that does not use exception handling
commands (or when calling one of its functions) from inside an active try
conditional of a new script, you might change the control flow of the existing
script on error. You get the immediate abortion on error and can catch the
error in the new script. If however the sourced script suppresses error
messages by using the ":silent!" command (checking for errors by testing
v:errmsg if appropriate), its execution path is not changed. The error is
not converted to an exception. (See :silent.) So the only remaining cause
where this happens is for scripts that don't care about errors and produce
error messages. You probably won't want to use such code from your new
scripts.

except-syntax-err

Syntax errors in the exception handling commands are never caught by any of
the ":catch" commands of the try conditional they belong to. Its finally
clauses, however, is executed.
   Example:

```
:try
:  try
:    throw 4711
:  catch /\(/
:    echo "in catch with syntax error"
:  catch
:    echo "inner catch-all"
:  finally
:    echo "inner finally"
:  endtry
:catch
:  echo 'outer catch-all caught "' .. v:exception .. '"'
:  finally
:    echo "outer finally"
:endtry
```

This displays:

```
inner finally
outer catch-all caught "Vim(catch):E54: Unmatched \("
outer finally
```

The original exception is discarded and an error exception is raised, instead.

except-single-line

The ":try", ":catch", ":finally", and ":endtry" commands can be put on
a single line, but then syntax errors may make it difficult to recognize the
"catch" line, thus you better avoid this.
   Example:

```
:try | unlet! foo # | catch | endtry
```

raises an error exception for the trailing characters after the ":unlet!"
argument, but does not see the ":catch" and ":endtry" commands, so that the
error exception is discarded and the "E488: Trailing characters" message gets
displayed.

except-several-errors

When several errors appear in a single command, the first error message is
usually the most specific one and therefore converted to the error exception.
   Example:

```
echo novar
```

causes

```
E121: Undefined variable: novar
E15: Invalid expression: novar
```

The value of the error exception inside try conditionals is:

```
Vim(echo):E121: Undefined variable: novar
```

except-syntax-error

But when a syntax error is detected after a normal error in the same command,
the syntax error is used for the exception being thrown.
   Example:

```
unlet novar #
```

causes

```
E108: No such variable: "novar"
E488: Trailing characters
```

The value of the error exception inside try conditionals is:

```
Vim(unlet):E488: Trailing characters
```

This is done because the syntax error might change the execution path in a way
not intended by the user. Example:

```
try
    try | unlet novar # | catch | echo v:exception | endtry
catch /.*/
    echo "outer catch:" v:exception
endtry
```

This displays "outer catch: Vim(unlet):E488: Trailing characters", and then
a "E600: Missing :endtry" error message is given, see except-single-line.

9. Examples eval-examples

Printing in Binary

```
:" The function Nr2Bin() returns the binary string representation of a number.
:func Nr2Bin(nr)
:  let n = a:nr
:  let r = ""
:  while n
:    let r = '01'[n % 2] .. r
:    let n = n / 2
:  endwhile
:  return r
:endfunc

:" The function String2Bin() converts each character in a string to a
:" binary string, separated with dashes.
:func String2Bin(str)
:  let out = ''
:  for ix in range(strlen(a:str))
:    let out = out .. '-' .. Nr2Bin(char2nr(a:str[ix]))
:  endfor
:  return out[1:]
:endfunc
```

Example of its use:

```
:echo Nr2Bin(32)
```

result: "100000"

```
:echo String2Bin("32")
```

result: "110011-110010"

Sorting lines

This example sorts lines with a specific compare function.

```
:func SortBuffer()
:  let lines = getline(1, '$')
:  call sort(lines, function("Strcmp"))
:  call setline(1, lines)
:endfunction
```

As a one-liner:

```
:call setline(1, sort(getline(1, '$'), function("Strcmp")))
```

scanf() replacement

sscanf

There is no sscanf() function in Vim. If you need to extract parts from a
line, you can use matchstr() and substitute() to do it. This example shows

how to get the file name, line number and column number out of a line like
"foobar.txt, 123, 45".

```
:" Set up the match bit
:let mx='\(\f\+\),\s*\(\d\+\),\s*\(\d\+\)'
:"get the part matching the whole expression
:let l = matchstr(line, mx)
:"get each item out of the match
:let file = substitute(l, mx, '\1', '')
:let lnum = substitute(l, mx, '\2', '')
:let col = substitute(l, mx, '\3', '')
```

The input is in the variable "line", the results in the variables "file",
"lnum" and "col". (idea from Michael Geddes)

getting the scriptnames in a Dictionary

scriptnames-dictionary

The :scriptnames command can be used to get a list of all script files that
have been sourced. There is also the getscriptinfo() function, but the
information returned is not exactly the same. In case you need to manipulate
the output of scriptnames this code can be used:

```
" Get the output of ":scriptnames" in the scriptnames_output variable.
let scriptnames_output = ''
redir => scriptnames_output
silent scriptnames
redir END

" Split the output into lines and parse each line.      Add an entry to the
" "scripts" dictionary.
let scripts = {}
for line in split(scriptnames_output, "\n")
  " Only do non-blank lines.
  if line =~ '\S'
    " Get the first number in the line.
    let nr = matchstr(line, '\d\+')
    " Get the file name, remove the script number " 123: ".
    let name = substitute(line, '.\+:\s*', '', '')
    " Add an item to the Dictionary
    let scripts[nr] = name
  endif
endfor
unlet scriptnames_output
```

The sandbox

eval-sandbox sandbox E523

The 'foldexpr', 'formatexpr', 'includeexpr', 'indentexpr', 'statusline' and
'foldtext' options may be evaluated in a sandbox. This means that you are
protected from these expressions having nasty side effects. This gives some
safety for when these options are set from a modeline. It is also used when
the command from a tags file is executed and for CTRL-R = in the command line.
The sandbox is also used for the :sandbox command.

E48

These items are not allowed in the sandbox:

- changing the buffer text
- defining or changing mapping, autocommands, user commands
- setting certain options (see option-summary)
- setting certain v: variables (see v:var) E794
- executing a shell command
- reading or writing a file
- jumping to another buffer or editing a file
- executing Python, Perl, etc. commands

  This is not guaranteed 100% secure, but it should block most attacks.

:san :sandbox

:san[dbox] {cmd} Execute {cmd} in the sandbox. Useful to evaluate an option that may have been set from a modeline, e.g. 'foldexpr'.

sandbox-option

A few options contain an expression. When this expression is evaluated it may have to be done in the sandbox to avoid a security risk. But the sandbox is restrictive, thus this only happens when the option was set from an insecure location. Insecure in this context are:

- sourcing a .nvimrc or .exrc in the current directory
- while executing in the sandbox
- value coming from a modeline
- executing a function that was defined in the sandbox

Note that when in the sandbox and saving an option value and restoring it, the option will still be marked as it was set in the sandbox.

Textlock

textlock

In a few situations it is not allowed to change the text in the buffer, jump to another window and some other things that might confuse or break what Vim is currently doing. This mostly applies to things that happen when Vim is actually doing something else. For example, a TextYankPost autocommand cannot edit the text it is yanking.

This is not allowed when the textlock is active:

- changing the buffer text
- jumping to another buffer or window
- editing another file
- closing a window or quitting Vim
- etc.

Vim script library

vimscript-library

Vim comes bundled with a Vim script library, that can be used by runtime, script authors. Currently, it only includes very few functions, but it may grow over time.

dist#vim

The functions make use of the autoloaded prefix "dist#vim".

The following functions are available:

dist#vim#IsSafeExecutable(filetype, executable)

This function takes a filetype and an executable and checks whether it is safe to execute the given executable. For security reasons users may not want to have Vim execute random executables or may have forbidden to do so for specific filetypes by setting the "<filetype>_exec" variable (plugin_exec).

It returns TRUE or FALSE to indicate whether the plugin should run the given executable. It takes the following arguments:

argument	type
filetype	string
executable	string

Command-line expressions highlighting

expr-highlight

Expressions entered by the user in i_CTRL-R_=, c_CTRL-_e, quote= are highlighted by the built-in expressions parser. It uses highlight groups described in the table below, which may be overridden by colorschemes.

hl-NvimInvalid

Besides the "Nvim"-prefixed highlight groups described below, there are "NvimInvalid"-prefixed highlight groups which have the same meaning but indicate that the token contains an error or that an error occurred just before it. They have mostly the same hierarchy, except that (by default) in place of any non-Nvim-prefixed group NvimInvalid linking to Error is used and some other intermediate groups are present.

Group	Default link	Colored expression
hl-NvimInternalError	None, red/red	Parser bug
hl-NvimAssignment	Operator	Generic assignment
hl-NvimPlainAssignment	NvimAssignment	= in :let
hl-NvimAugmentedAssignment	NvimAssignment	Generic, +=/`-=`/`.=`
hl-NvimAssignmentWithAddition	NvimAugmentedAssignment	+= in :let+=

hl-NvimAssignmentWithSubtraction	NvimAugmentedAssignment	-= in :let-=
hl-NvimAssignmentWithConcatenation	NvimAugmentedAssignment	.= in :let.=
hl-NvimOperator	Operator	Generic operator
hl-NvimUnaryOperator	NvimOperator	Generic unary op
hl-NvimUnaryPlus	NvimUnaryOperator	expr-unary-+
hl-NvimUnaryMinus	NvimUnaryOperator	expr-unary--
hl-NvimNot	NvimUnaryOperator	expr-!
hl-NvimBinaryOperator	NvimOperator	Generic binary op
hl-NvimComparison	NvimBinaryOperator	Any expr4 operator
hl-NvimComparisonModifier	NvimComparison	#/`?` near expr4 op
hl-NvimBinaryPlus	NvimBinaryOperator	expr-+
hl-NvimBinaryMinus	NvimBinaryOperator	expr--
hl-NvimConcat	NvimBinaryOperator	expr-.
hl-NvimConcatOrSubscript	NvimConcat	expr-. or expr-entry
hl-NvimOr	NvimBinaryOperator	expr-barbar
hl-NvimAnd	NvimBinaryOperator	expr-&&
hl-NvimMultiplication	NvimBinaryOperator	expr-star
hl-NvimDivision	NvimBinaryOperator	expr-/
hl-NvimMod	NvimBinaryOperator	expr-%
hl-NvimTernary	NvimOperator	? in expr1
hl-NvimTernaryColon	NvimTernary	: in expr1
hl-NvimParenthesis	Delimiter	Generic bracket
hl-NvimLambda	NvimParenthesis	{/`}` in lambda
hl-NvimNestingParenthesis	NvimParenthesis	(/`)` in expr-nesting
hl-NvimCallingParenthesis	NvimParenthesis	(/`)` in expr-function
hl-NvimSubscript	NvimParenthesis	Generic subscript
hl-NvimSubscriptBracket	NvimSubscript	[/`]` in expr-[]
hl-NvimSubscriptColon	NvimSubscript	: in expr-[:]
hl-NvimCurly	NvimSubscript	{/`}` in curly-braces-names
hl-NvimContainer	NvimParenthesis	Generic container
hl-NvimDict	NvimContainer	{/`}` in dict literal
hl-NvimList	NvimContainer	[/`]` in list literal
hl-NvimIdentifier	Identifier	Generic identifier
hl-NvimIdentifierScope	NvimIdentifier	Namespace: letter before : in internal-variables
hl-NvimIdentifierScopeDelimiter	NvimIdentifier	: after namespace letter
hl-NvimIdentifierName	NvimIdentifier	Rest of the ident
hl-NvimIdentifierKey	NvimIdentifier	Identifier after expr-entry
hl-NvimColon	Delimiter	: in dict literal
hl-NvimComma	Delimiter	, in dict or list literal or expr-function
hl-NvimArrow	Delimiter	-> in lambda
hl-NvimRegister	SpecialChar	expr-register
hl-NvimNumber	Number	Non-prefix digits in integer expr-number
hl-NvimNumberPrefix	Type	0 for octal-number 0x for hex-number 0b for binary-number
hl-NvimFloat	NvimNumber	Floating-point number
hl-NvimOptionSigil	Type	& in expr-option
hl-NvimOptionScope	NvimIdentifierScope	Option scope if any
hl-NvimOptionScopeDelimiter	NvimIdentifierScopeDelimiter	: after option scope
hl-NvimOptionName	NvimIdentifier	Option name
hl-NvimEnvironmentSigil	NvimOptionSigil	$ in expr-env
hl-NvimEnvironmentName	NvimIdentifier	Env variable name
hl-NvimString	String	Generic string
hl-NvimStringBody	NvimString	Generic string literal body
hl-NvimStringQuote	NvimString	Generic string quote
hl-NvimStringSpecial	SpecialChar	Generic string non-literal body
hl-NvimSingleQuote	NvimStringQuote	' in expr-'
hl-NvimSingleQuotedBody	NvimStringBody	Literal part of expr-' string body
hl-NvimSingleQuotedQuote	NvimStringSpecial	'' inside expr-' string body
hl-NvimDoubleQuote	NvimStringQuote	" in expr-quote
hl-NvimDoubleQuotedBody	NvimStringBody	Literal part of expr-quote body
hl-NvimDoubleQuotedEscape	NvimStringSpecial	Valid expr-quote escape sequence
hl-NvimDoubleQuotedUnknownEscape	NvimInvalidValue	Unrecognized expr-quote escape sequence

Vimscript functions builtin.txt

For functions grouped by what they are used for see function-list.

1. Details vimscript-functions-details

abs({expr}) abs()

Lua: Prefer math.abs().

Return the absolute value of {expr}. When {expr} evaluates to a Float abs() returns a Float. When {expr} can be converted to a Number abs() returns a Number. Otherwise abs() gives an error message and returns -1.
Examples:

```
echo abs(1.456)
```

1.456

```
echo abs(-5.456)
```

5.456

```
echo abs(-4)
```

4

Parameters:
- {expr} (number)

Return:
(number)

acos({expr}) acos()

Lua: Prefer math.acos().

Return the arc cosine of {expr} measured in radians, as a Float in the range of [0, pi].
{expr} must evaluate to a Float or a Number in the range [-1, 1].
Returns NaN if {expr} is outside the range [-1, 1]. Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo acos(0)
```

1.570796

```
echo acos(-0.5)
```

2.094395

Parameters:
- {expr} (number)

Return:
(number)

add({object}, {expr}) add()

Lua: Prefer table.insert() for lists and .. for blobs.

Append the item {expr} to List or Blob {object}. Returns the resulting List or Blob. Examples:

```
let alist = add([1, 2, 3], item)
call add(mylist, "woodstock")
```

Note that when {expr} is a List it is appended as a single item. Use extend() to concatenate Lists.
When {object} is a Blob then {expr} must be a number.
Use insert() to add an item at another position.
Returns 1 if {object} is not a List or a Blob.

Parameters:
- {object} (any)
- {expr} (any)

Return:
(any) Resulting List or Blob, or 1 if {object} is not a List or a Blob.

and({expr}, {expr}) and()

Lua: Prefer bit.band().

Bitwise AND on the two arguments. The arguments are converted
to a number. A List, Dict or Float argument causes an error.
Also see or() and xor().
Example:

```
let flag = and(bits, 0x80)
```

Parameters:
- {expr} (number)

- {expr1} (number)

Return:
(integer)

api_info() api_info()

Returns Dictionary of api-metadata.

View it in a nice human-readable format:

```
lua vim.print(vim.fn.api_info())
```

Attributes:
api-fast

Return:
(table)

append({lnum}, {text}) append()

Lua: Prefer nvim_buf_set_lines().

When {text} is a List: Append each item of the List as a
text line below line {lnum} in the current buffer.
Otherwise append {text} as one text line below line {lnum} in
the current buffer.
Any type of item is accepted and converted to a String.
{lnum} can be zero to insert a line before the first one.
{lnum} is used like with getline().
Returns 1 for failure ({lnum} out of range or out of memory),
0 for success. When {text} is an empty list zero is returned,
no matter the value of {lnum}. Example:

```
let failed = append(line('$'), "# THE END")
let failed = append(0, ["Chapter 1", "the beginning"])
```

Parameters:
- {lnum} (integer|string)

- {text} (string|string[])

Return:
(0|1)

appendbufline({buf}, {lnum}, {text}) appendbufline()

Lua: Prefer nvim_buf_set_lines().

Like append() but append the text in buffer {buf}.

This function works only for loaded buffers. First call
bufload() if needed.

For the use of {buf}, see bufname().

{lnum} is the line number to append below. Note that using
line() would use the current buffer, not the one appending
to. Use "$" to append at the end of the buffer. Other string
values are not supported.

On success 0 is returned, on failure 1 is returned.

If {buf} is not a valid buffer or {lnum} is not valid, an
error message is given. Example:

```
let failed = appendbufline(13, 0, "# THE START")
```

However, when {text} is an empty list then no error is given
for an invalid {lnum}, since {lnum} isn't actually used.

Parameters:
- {buf} (integer|string)

- {lnum} (integer)

- {text} (string)

Return:

(0|1)

argc([{winid}]) argc()

The result is the number of files in the argument list. See arglist.
If {winid} is not supplied, the argument list of the current window is used.
If {winid} is -1, the global argument list is used.
Otherwise {winid} (a window-number or window-ID) specifies the window of which the argument list is used.
Returns -1 if the {winid} argument is invalid.

Parameters:
- {winid} (integer?)

Return:
(integer)

argidx() argidx()

The result is the current index in the argument list. 0 is the first file. argc() - 1 is the last one. See arglist.

Return:
(integer)

arglistid([{winnr} [, {tabnr}]]) arglistid()

Return the argument list ID. This is a number which identifies the argument list being used. Zero is used for the global argument list. See arglist.
Returns -1 if the arguments are invalid.

Without arguments use the current window.
With {winnr} only use this window in the current tabpage.
With {winnr} and {tabnr} use the window in the specified tab page.
{winnr} is a window-number or window-ID.

Parameters:
- {winnr} (integer?)
- {tabnr} (integer?)

Return:
(integer)

argv([{nr} [, {winid}]]) argv()

The result is the {nr}th file in the argument list. See arglist. "argv(0)" is the first one. Example:

```
let i = 0
while i < argc()
  let f = escape(fnameescape(argv(i)), '.')
  exe 'amenu Arg.' .. f .. ' :e ' .. f .. '<CR>'
  let i = i + 1
endwhile
```

Without the {nr} argument, or when {nr} is -1, a List with the whole arglist is returned.

The {winid} argument is a window-ID, see argc().
For the Vim command line arguments see v:argv.

Returns an empty string if {nr}th argument is not present in the argument list. Returns an empty List if the {winid} argument is invalid.

Parameters:
- {nr} (integer?)
- {winid} (integer?)

Return:
(string|string[])

asin({expr}) asin()

Lua: Prefer math.asin().

Return the arc sine of {expr} measured in radians, as a Float in the range of [-pi/2, pi/2].
{expr} must evaluate to a Float or a Number in the range [-1, 1].
Returns NaN if {expr} is outside the range [-1, 1]. Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo asin(0.8)
```

0.927295

```
echo asin(-0.5)
```

-0.523599

Parameters:
- {expr} (any)

Return:
(number)

assert_beeps({cmd}) assert_beeps()

Run {cmd} and add an error message to v:errors if it does NOT produce a beep or visual bell.
Also see assert_fails(), assert_nobeep() and assert-return.

Parameters:
- {cmd} (string)

Return:
(0|1)

assert_equal({expected}, {actual} [, {msg}]) assert_equal()

Lua: Prefer assert() with vim.deep_equal().

When {expected} and {actual} are not equal an error message is added to v:errors and 1 is returned. Otherwise zero is returned. assert-return
The error is in the form "Expected {expected} but got {actual}". When {msg} is present it is prefixed to that, along with the location of the assert when run from a script.

There is no automatic conversion, the String "4" is different from the Number 4. And the number 4 is different from the Float 4.0. The value of 'ignorecase' is not used here, case always matters.
Example:

```
call assert_equal('foo', 'bar', 'baz')
```

Will add the following to v:errors:

```
test.vim line 12: baz: Expected 'foo' but got 'bar'
```

Parameters:
- {expected} (any)
- {actual} (any)
- {msg} (any?)

Return:
(0|1)

assert_equalfile({fname_one}, {fname_two}) assert_equalfile()

When the files {fname_one} and {fname_two} do not contain exactly the same text an error message is added to v:errors.
Also see assert-return.
When {fname_one} or {fname_two} does not exist the error will mention that.

Parameters:
- {fname_one} (string)
- {fname_two} (string)

Return:
(0|1)

assert_exception({error} [, {msg}]) assert_exception()

When v:exception does not contain the string {error} an error message is added to v:errors. Also see assert-return.
This can be used to assert that a command throws an exception. Using the error number, followed by a colon, avoids problems with translations:

```
try
  commandthatfails
  call assert_false(1, 'command should have failed')
catch
  call assert_exception('E492:')
endtry
```

Parameters:
- {error} (any)

- {msg} (any?)

Return:
(0|1)

assert_fails() assert_fails({cmd} [, {error} [, {msg} [, {lnum} [, {context}]]]])

Run {cmd} and add an error message to v:errors if it does NOT produce an error or when {error} is not found in the error message. Also see assert-return.

When {error} is a string it must be found literally in the first reported error. Most often this will be the error code, including the colon, e.g. "E123:".

```
call assert_fails('bad cmd', 'E987:')
```

When {error} is a List with one or two strings, these are used as patterns. The first pattern is matched against the first reported error:

```
call assert_fails('cmd', ['E987:.*expected bool'])
```

The second pattern, if present, is matched against the last reported error. To only match the last error use an empty string for the first error:

```
call assert_fails('cmd', ['', 'E987:'])
```

If {msg} is empty then it is not used. Do this to get the default message when passing the {lnum} argument.

E1115

When {lnum} is present and not negative, and the {error} argument is present and matches, then this is compared with the line number at which the error was reported. That can be the line number in a function or in a script.

E1116

When {context} is present it is used as a pattern and matched against the context (script name or function name) where {lnum} is located in.

Note that beeping is not considered an error, and some failing commands only beep. Use assert_beeps() for those.

Parameters:
- {cmd} (string)

- {error} (any?)

- {msg} (any?)

- {lnum} (integer?)

- {context} (any?)

Return:
(0|1)

assert_false() assert_false({actual} [, {msg}])

Lua: Prefer assert().

When {actual} is not false an error message is added to v:errors, like with assert_equal().
The error is in the form "Expected False but got {actual}".
When {msg} is present it is prefixed to that, along with the location of the assert when run from a script.
Also see assert-return.

A value is false when it is zero. When {actual} is not a number the assert fails.

Parameters:

- {actual} (any)

- {msg} (any?)

Return:
(0|1)

assert_inrange({lower}, {upper}, {actual} [, {msg}]) assert_inrange()

Lua: Prefer assert().

This asserts number and Float values. When {actual} is lower than {lower} or higher than {upper} an error message is added to v:errors. Also see assert-return.
The error is in the form "Expected range {lower} - {upper}, but got {actual}". When {msg} is present it is prefixed to that.

Parameters:
- {lower} (number)

- {upper} (number)

- {actual} (number)

- {msg} (string?)

Return:
(0|1)

assert_match({pattern}, {actual} [, {msg}]) assert_match()

When {pattern} does not match {actual} an error message is added to v:errors. Also see assert-return.
The error is in the form "Pattern {pattern} does not match {actual}". When {msg} is present it is prefixed to that, along with the location of the assert when run from a script.

{pattern} is used as with expr-=~: The matching is always done like 'magic' was set and 'cpoptions' is empty, no matter what the actual value of 'magic' or 'cpoptions' is.

{actual} is used as a string, automatic conversion applies. Use "^" and "$" to match with the start and end of the text. Use both to match the whole text.

Example:

```
call assert_match('^f.*o$', 'foobar')
```

Will result in a string to be added to v:errors:

```
test.vim line 12: Pattern '^f.*o$' does not match 'foobar'
```

Parameters:
- {pattern} (string)

- {actual} (string)

- {msg} (string?)

Return:
(0|1)

assert_nobeep({cmd}) assert_nobeep()

Run {cmd} and add an error message to v:errors if it produces a beep or visual bell.
Also see assert_beeps().

Parameters:
- {cmd} (string)

Return:
(0|1)

assert_notequal({expected}, {actual} [, {msg}]) assert_notequal()

The opposite of assert_equal(): add an error message to v:errors when {expected} and {actual} are equal.
Also see assert-return.

Parameters:

- {expected} (any)

- {actual} (any)

- {msg} (any?)

Return:
(0|1)

assert_notmatch({pattern}, {actual} [, {msg}]) assert_notmatch()

The opposite of assert_match(): add an error message to
v:errors when {pattern} matches {actual}.
Also see assert-return.

Parameters:
- {pattern} (string)

- {actual} (string)

- {msg} (string?)

Return:
(0|1)

assert_report({msg}) assert_report()

Report a test failure directly, using String {msg}.
Always returns one.

Parameters:
- {msg} (string)

Return:
(0|1)

assert_true({actual} [, {msg}]) assert_true()

Lua: Prefer assert().

When {actual} is not true an error message is added to
v:errors, like with assert_equal().
Also see assert-return.
A value is TRUE when it is a non-zero number or v:true.
When {actual} is not a number or v:true the assert fails.
When {msg} is given it is prefixed to the default message,
along with the location of the assert when run from a script.

Parameters:
- {actual} (any)

- {msg} (string?)

Return:
(0|1)

atan({expr}) atan()

Lua: Prefer math.atan().

Return the principal value of the arc tangent of {expr}, in
the range [-pi/2, +pi/2] radians, as a Float.
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo atan(100)
```

```
1.560797
```

```
echo atan(-4.01)
```

```
-1.326405
```

Parameters:
- {expr} (number)

Return:
(number)

atan2({expr1}, {expr2}) atan2()

Lua: Prefer math.atan2().

Return the arc tangent of {expr1} / {expr2}, measured in
radians, as a Float in the range [-pi, pi].
{expr1} and {expr2} must evaluate to a Float or a Number.
Returns 0.0 if {expr1} or {expr2} is not a Float or a
Number.
Examples:

```
echo atan2(-1, 1)
```

```
-0.785398
```

```
echo atan2(1, -1)
```

```
2.356194
```

Parameters:

- {expr1} (number)
- {expr2} (number)

Return:

(number)

blob2list({blob}) blob2list()

Return a List containing the number value of each byte in Blob
{blob}. Examples:

```
blob2list(0z0102.0304)  " returns [1, 2, 3, 4]
blob2list(0z)           " returns []
```

Returns an empty List on error. list2blob() does the
opposite.

Parameters:

- {blob} (any)

Return:

(any[])

browse({save}, {title}, {initdir}, {default}) browse()

Put up a file requester. This only works when "has("browse")"
returns TRUE (only in some GUI versions).
The input fields are:
    {save}   when TRUE, select file to write
    {title}   title for the requester
    {initdir}   directory to start browsing in
    {default}   default file name
An empty string is returned when the "Cancel" button is hit,
something went wrong, or browsing is not possible.

Parameters:

- {save} (any)
- {title} (string)
- {initdir} (string)
- {default} (string)

Return:

(0|1)

browsedir({title}, {initdir}) browsedir()

Put up a directory requester. This only works when
"has("browse")" returns TRUE (only in some GUI versions).
On systems where a directory browser is not supported a file
browser is used. In that case: select a file in the directory
to be used.
The input fields are:
    {title}   title for the requester
    {initdir}   directory to start browsing in
When the "Cancel" button is hit, something went wrong, or
browsing is not possible, an empty string is returned.

Parameters:

- {title} (string)
- {initdir} (string)

Return:

(0|1)

bufadd({name}) bufadd()

Adds buffer {name} to the buffer-list literally: no special chars or expansion are applied (including "~"). Returns the new (or existing matching) buffer number, or 0 on error.

The buffer is not loaded and 'buflisted' is not set. When {name} is an empty string, a new buffer is always created.

Example (Lua):

```
local buf = vim.fn.bufadd(vim.fs.normalize('someName'))
-- Set 'buflisted'; trigger BufReadPre/BufReadPost/FileType.
vim.api.nvim_buf_call(buf, vim.cmd.edit)
```

Parameters:
- {name} (string)

Return:
(integer)

bufexists({buf}) bufexists()

Lua: Prefer nvim_buf_is_valid() after resolving {buf} to a bufnr.

Checks whether a buffer with the name or number {buf} exists. Returns TRUE if the buffer exists, FALSE otherwise.
If the {buf} argument is a number, buffer numbers are used. Number zero is the alternate buffer for the current window.

If the {buf} argument is a string it must match a buffer name exactly. The name can be:
- Relative to the current directory.
- A full path.
- The name of a buffer with 'buftype' set to "nofile".
- A URL name.

Unlisted buffers will be found.
Note that help files are listed by their short name in the output of :buffers, but bufexists() requires using their long name to be able to find them.
bufexists() may report a buffer exists, but to use the name with a :buffer command you may need to use expand(). Esp for MS-Windows 8.3 names in the form "c:\DOCUME~1"
Use "bufexists(0)" to test for the existence of an alternate file name.

Parameters:
- {buf} (any)

Return:
(0|1)

buflisted({buf}) buflisted()

Lua: Prefer vim.bo or nvim_get_option_value() after resolving {buf} to a bufnr.

Checks whether a buffer called {buf} exists and is listed (has the 'buflisted' option set). Returns TRUE if so, FALSE otherwise.
The {buf} argument is used like with bufexists().

Parameters:
- {buf} (any)

Return:
(0|1)

bufload({buf}) bufload()

Ensure the buffer {buf} is loaded. When the buffer name refers to an existing file then the file is read. Otherwise the buffer will be empty. If the buffer was already loaded then there is no change. If the buffer is not related to a file then no file is read (e.g., when 'buftype' is "nofile"). If there is an existing swap file for the file of the buffer, there will be no dialog, the buffer will be loaded anyway.
The {buf} argument is used like with bufexists().

Parameters:

- {buf} (any)

bufloaded({buf}) bufloaded()

Lua: Prefer nvim_buf_is_loaded() after resolving {buf} to a bufnr.

Checks whether a buffer called {buf} exists and is loaded (shown in a window or hidden). Returns TRUE if so, FALSE otherwise.
The {buf} argument is used like with bufexists().

Parameters:
- {buf} (any)

Return:
(0|1)

bufname([{buf}]) bufname()

Lua: Prefer nvim_buf_get_name() after resolving {buf} to a bufnr.

The result is the name of a buffer. Mostly as it is displayed by the :ls command, but not using special names such as "[No Name]". If the buffer represents a directory, the name ends with a path separator, unless it was changed by :file or nvim_buf_set_name().
If {buf} is omitted the current buffer is used.
If {buf} is a Number, that buffer number's name is given. Number zero is the alternate buffer for the current window.
If {buf} is a String, it is used as a file-pattern to match with the buffer names. This is always done like 'magic' is set and 'cpoptions' is empty. When there is more than one match an empty string is returned.
"" or "%" can be used for the current buffer, "#" for the alternate buffer.
A full match is preferred, otherwise a match at the start, end or middle of the buffer name is accepted. If you only want a full match then put "^" at the start and "$" at the end of the pattern.
Listed buffers are found first. If there is a single match with a listed buffer, that one is returned. Next unlisted buffers are searched for.
If the {buf} is a String, but you want to use it as a buffer number, force it to be a Number by adding zero to it:

```
echo bufname("3" + 0)
```

If the buffer doesn't exist, or doesn't have a name, an empty string is returned.

```
echo bufname("#")       " alternate buffer name
echo bufname(3)         " name of buffer 3
echo bufname("%")       " name of current buffer
echo bufname("file2")   " name of buffer where "file2" matches.
```

Parameters:
- {buf} (integer|string?)

Return:
(string)

bufnr([{buf} [, {create}]]) bufnr()

Lua: Prefer nvim_get_current_buf() when omitted, or nvim_create_buf() with nvim_buf_set_name() for creating; name lookup, "$", "%", "#", and {create} semantics differ.

The result is the number of a buffer, as it is displayed by the :ls command. For the use of {buf}, see bufname() above.
If the buffer doesn't exist, -1 is returned. Or, if the {create} argument is present and TRUE, a new, unlisted, buffer is created and its number is returned. Example:

```
let newbuf = bufnr('Scratch001', 1)
```

Using an empty name uses the current buffer. To create a new buffer with an empty name use bufadd().

bufnr("$") is the last buffer:

```
let last_buffer = bufnr("$")
```

The result is a Number, which is the highest buffer number of existing buffers. Note that not all buffers with a smaller number necessarily exist, because ":bwipeout" may have removed them. Use bufexists() to test for the existence of a buffer.

Parameters:
- {buf} (integer|string?)

- {create} (any?)

Return:
(integer)

bufwinid({buf}) bufwinid()

Lua: Prefer nvim_tabpage_list_wins() with nvim_win_get_buf() after resolving {buf}; only the current tabpage is checked and no-match semantics differ.

Returns the window-ID of the first window associated with buffer {buf}. For the use of {buf}, see bufname() above. If buffer {buf} doesn't exist or there is no such window, -1 is returned. Example:

```
echo "A window containing buffer 1 is " .. (bufwinid(1))
```

Only deals with the current tabpage. See win_findbuf() for finding more.

Parameters:
- {buf} (any)

Return:
(integer)

bufwinnr({buf}) bufwinnr()

Lua: Prefer nvim_tabpage_list_wins() with nvim_win_get_buf() and nvim_win_get_number() after resolving {buf}; only the current tabpage is checked and no-match semantics differ.

Like bufwinid() but returns a window-number instead of a window-ID.
If buffer {buf} doesn't exist or there is no such window, -1 is returned. Example:

```
echo "A window containing buffer 1 is " .. (bufwinnr(1))
```

The number can be used with CTRL-W w and ":wincmd w" :wincmd.

Parameters:
- {buf} (any)

Return:
(integer)

byte2line({byte}) byte2line()

Return the line number that contains the character at byte count {byte} in the current buffer. This includes the end-of-line character, depending on the 'fileformat' option for the current buffer. The first character has byte count one.
Also see line2byte(), go and :goto.

Returns -1 if the {byte} value is invalid.

Parameters:
- {byte} (any)

Return:
(integer)

byteidx({expr}, {nr} [, {utf16}]) byteidx()

Lua: Prefer vim.str_byteindex() for string input with "utf-32" or "utf-16" and strict_indexing = false; composing characters and out-of-range semantics differ.

Return byte index of the {nr}th character in the String {expr}. Use zero for the first character, it then returns zero.
If there are no multibyte characters the returned value is equal to {nr}.
Composing characters are not counted separately, their byte length is added to the preceding base character. See byteidxcomp() below for counting composing characters separately.
When {utf16} is present and TRUE, {nr} is used as the UTF-16 index in the String {expr} instead of as the character index.

The UTF-16 index is the index in the string when it is encoded
with 16-bit words. If the specified UTF-16 index is in the
middle of a character (e.g. in a 4-byte character), then the
byte index of the first byte in the character is returned.
Refer to string-offset-encoding for more information.
Example :

```
echo matchstr(str, ".", byteidx(str, 3))
```

will display the fourth character. Another way to do the
same:

```
let s = strpart(str, byteidx(str, 3))
echo strpart(s, 0, byteidx(s, 1))
```

Also see strgetchar() and strcharpart().

If there are less than {nr} characters -1 is returned.
If there are exactly {nr} characters the length of the string
in bytes is returned.
See charidx() and utf16idx() for getting the character and
UTF-16 index respectively from the byte index.
Examples:

```
echo byteidx('a😊😊', 2)        " returns 5
echo byteidx('a😊😊', 2, 1)     " returns 1
echo byteidx('a😊😊', 3, 1)     " returns 5
```

Attributes:
api-fast

Parameters:
- {expr} (any)
- {nr} (integer)
- {utf16} (any?)

Return:
(integer)

byteidxcomp({expr}, {nr} [, {utf16}]) byteidxcomp()

Lua: Prefer vim.str_byteindex() with "utf-32" or
"utf-16" and strict_indexing = false.

Like byteidx(), except that a composing character is counted
as a separate character. Example:

```
let s = 'e' .. nr2char(0x301)
echo byteidx(s, 1)
echo byteidxcomp(s, 1)
echo byteidxcomp(s, 2)
```

The first and third echo result in 3 ('e' plus composing
character is 3 bytes), the second echo results in 1 ('e' is
one byte).

Attributes:
api-fast

Parameters:
- {expr} (any)
- {nr} (integer)
- {utf16} (any?)

Return:
(integer)

call({func}, {arglist} [, {dict}]) call() E699

Call function {func} with the items in List {arglist} as
arguments.
{func} can either be a Funcref or the name of a function.
a:firstline and a:lastline are set to the cursor line.
Returns the return value of the called function.
{dict} is for functions with the "dict" attribute. It will be
used to set the local variable "self". Dictionary-function

Parameters:
- {func} (any)
- {arglist} (any)

- {dict} (any?)

Return:
(any)

ceil({expr}) ceil()

Lua: Prefer math.ceil().

Return the smallest integral value greater than or equal to
{expr} as a Float (round up).
{expr} must evaluate to a Float or a Number.
Examples:

```
echo ceil(1.456)
```

2.0

```
echo ceil(-5.456)
```

-5.0

```
echo ceil(4.0)
```

4.0

Returns 0.0 if {expr} is not a Float or a Number.

Parameters:
- {expr} (number)

Return:
(number)

chanclose({id} [, {stream}]) chanclose()

Close a channel or a specific stream associated with it.
For a job, {stream} can be one of "stdin", "stdout",
"stderr" or "rpc" (closes stdin/stdout for a job started
with "rpc":v:true) If {stream} is omitted, all streams
are closed. If the channel is a pty, this will then close the
pty master, sending SIGHUP to the job process.
For a socket, there is only one stream, and {stream} should be
omitted.

Parameters:
- {id} (integer)
- {stream} (string?)

Return:
(0|1)

changenr() changenr()

Return the number of the most recent change. This is the same
number as what is displayed with :undolist and can be used
with the :undo command.
When a change was made it is the number of that change. After
redo it is the number of the redone change. After undo it is
one less than the number of the undone change.
Returns 0 if the undo list is empty.

Return:
(integer)

chansend({id}, {data}) chansend()

Lua: Prefer nvim_chan_send() for string (binary) data.

Send data to channel {id}. For a job, it writes it to the
stdin of the process. For the stdio channel channel-stdio,
it writes to Nvim's stdout. Returns the number of bytes
written if the write succeeded, 0 otherwise.
See channel-bytes for more information.

{data} may be a string, string convertible, Blob, or a list.

If {data} is a list, the items will be joined by newlines; any
newlines in an item will be sent as NUL; to send a final
newline, include a final empty string. NL-used-for-Nul

Example:

```
call chansend(id, ["abc", "123\n456", ""])
```

will send "abc<NL>123<NUL>456<NL>".

chansend() writes raw data, not RPC messages. If the channel
was created with "rpc":v:true then the channel expects RPC
messages, use rpcnotify() and rpcrequest() instead.

Parameters:

- {id} (number)

- {data} (string|string[])

Return:
(integer)

char2nr({string} [, {utf8}]) char2nr()

Lua: Prefer string.byte(): only works with ASCII.

Return Number value of the first char in {string}.
Examples:

```
echo char2nr(" ")       " returns 32
echo char2nr("ABC")     " returns 65
echo char2nr("á")       " returns 225
echo char2nr("á"[0])    " returns 195
echo char2nr("\<M-x>")  " returns 128
```

Non-ASCII characters are always treated as UTF-8 characters.
{utf8} is ignored, it exists only for backwards-compatibility.
A combining character is a separate character.
nr2char() does the opposite.

Returns 0 if {string} is not a String.

Attributes:
api-fast

Parameters:
- {string} (string)

- {utf8} (any?)

Return:
(0|1)

charclass({string}) charclass()

Return the character class of the first character in {string}.
The character class is one of:

0	blank
1	punctuation
2	word character (depends on 'iskeyword')
3	emoji
other	specific Unicode class

The class is used in patterns and word motions.
Returns 0 if {string} is not a String.

Parameters:
- {string} (string)

Return:
(0|1|2|3|'other')

charcol({expr} [, {winid}]) charcol()

Lua: Prefer nvim_win_get_cursor() with vim.str_utfindex()
for ".", or nvim_get_current_line() with
vim.str_utfindex() for "$"; marks, list input, and window
semantics differ.

Same as col() but returns the character index of the column
position given with {expr} instead of the byte position.

Example:
With the cursor on '□' in line 5 with text "□□□□":

```
echo charcol('.')       " returns 3
echo col('.')           " returns 7
```

Parameters:
- {expr} (string|any[])

- {winid} (integer?)

Return:
(integer)

charidx({string}, {idx} [, {countcc} [, {utf16}]]) charidx()

Lua: Prefer vim.str_utfindex() for string input with
"utf-32" or "utf-16" and strict_indexing = false;
countcc = false and out-of-range semantics differ.

Return the character index of the byte at {idx} in {string}.
The index of the first character is zero.

If there are no multibyte characters the returned value is
equal to {idx}.

When {countcc} is omitted or FALSE, then composing characters
are not counted separately, their byte length is added to the
preceding base character.
When {countcc} is TRUE, then composing characters are
counted as separate characters.

When {utf16} is present and TRUE, {idx} is used as the UTF-16
index in the String {expr} instead of as the byte index.

Returns -1 if the arguments are invalid or if there are less
than {idx} bytes. If there are exactly {idx} bytes the length
of the string in characters is returned.

An error is given and -1 is returned if the first argument is
not a string, the second argument is not a number or when the
third argument is present and is not zero or one.

See byteidx() and byteidxcomp() for getting the byte index
from the character index and utf16idx() for getting the
UTF-16 index from the character index.
Refer to string-offset-encoding for more information.
Examples:

```
echo charidx('áb́ć', 3)          " returns 1
echo charidx('áb́ć', 6, 1)       " returns 4
echo charidx('áb́ć', 16)         " returns -1
echo charidx('a😊😊', 4, 0, 1)  " returns 2
```

Attributes:
api-fast

Parameters:
- {string} (string)
- {idx} (integer)
- {countcc} (boolean?)
- {utf16} (boolean?)

Return:
(integer)

chdir({dir} [, {scope}]) chdir()

Sets the current-directory of the given {scope}:
- "buffer" Changes the buffer-local directory. :bcd
- "window" Changes the window-local directory. :lcd
- "tabpage" Changes the tabpage-local directory. :tcd
- "global" Changes the global directory. :cd

If {scope} is not given it is decided as follows:
- If buffer-local directory (:bcd) is set, scope is
  "buffer".
- If the window-local directory (:lcd) is set, scope is
  "window".
- If the tabpage-local directory (:tcd) is set, scope is
  "tabpage".
- Otherwise, scope is "global".

If successful, returns the previous working directory.
On failure, returns an empty string.

Example:

```
let save_dir = chdir(newdir)
if save_dir != ""
   " ... do some work
   call chdir(save_dir)
endif
```

Parameters:

- {dir} (string)

- {scope} (string?)

Return:
(string)

cindent({lnum}) cindent()

Get the amount of indent for line {lnum} according the C-indenting rules, as with 'cindent'.
The indent is counted in spaces, the value of 'tabstop' is relevant. {lnum} is used just like in getline().
When {lnum} is invalid -1 is returned.

To get or set indent of lines in a string, see vim.text.indent().

Parameters:
- {lnum} (integer|string)

Return:
(integer)

clearmatches([{win}]) clearmatches()

Clears all matches previously defined for the current window by matchadd() and the :match commands.
If {win} is specified, use this window-number or window-ID instead of the current window.

Parameters:
- {win} (integer?)

cmdcomplete_info() cmdcomplete_info()

Returns a Dictionary with information about cmdline completion. See cmdline-completion.
The items are:

cmdline_orig	The original command-line string before completion began.
pum_visible	TRUE if popup menu is visible. See pumvisible().
matches	List of all completion candidates. Each item is a string.
selected	Selected item index. First index is zero. Index is -1 if no item is selected (showing typed text only, or the last completion after no item is selected when using the <Up> or <Down> keys)

Returns an empty Dictionary if no completion was attempted, if there was only one candidate and it was fully completed, or if an error occurred.

Return:
(table<string,any>)

col({expr} [, {winid}]) col()

Lua: Prefer nvim_win_get_cursor() for "." (add 1), or Lua # on nvim_get_current_line() for "$"; marks, list input, and virtualedit differ.

Returns the byte index of the column position given with {expr}.
For accepted positions see getpos().
When {expr} is "$", it means the end of the cursor line, so the result is the number of bytes in the cursor line plus one.
Additionally {expr} can be [lnum, col]: a List with the line and column number. Most useful when the column is "$", to get the last column of a specific line. When "lnum" or "col" is out of range then col() returns zero.

With the optional {winid} argument the values are obtained for that window instead of the current window.

To get the line number use line(). To get both use getpos().

For the screen column position use virtcol(). For the character position use charcol().

Note that only marks in the current file can be used.

Examples:

```
echo col(".")                   " column of cursor
echo col("$")                   " length of cursor line plus one
echo col("'t")                  " column of mark t
echo col("'" .. markname)       " column of mark markname
```

The first column is 1. Returns 0 if {expr} is invalid or when the window with ID {winid} is not found.
For an uppercase mark the column may actually be in another buffer.
For the cursor position, when 'virtualedit' is active, the column is one higher if the cursor is after the end of the line. Also, when using a <Cmd> mapping the cursor isn't moved, this can be used to obtain the column in Insert mode:

```
imap <F2> <Cmd>echo col(".")."\n"<CR>
```

Parameters:
- {expr} (string|any[])

- {winid} (integer?)

Return:
(integer)

complete({startcol}, {matches}) complete() E785

Set the matches for Insert mode completion. Can only be used in Insert mode. Typically invoked from a mapping with CTRL-R = (see i_CTRL-R), but may also be called from a <Cmd> mapping. It does not work after CTRL-O or with an expression mapping.
{startcol} is the byte offset in the line where the completed text start. The text up to the cursor is the original text that will be replaced by the matches. Use col('.') for an empty string. "col('.') - 1" will replace one character by a match.
{matches} must be a List. Each List item is one match.
See complete-items for the kind of items that are possible.
"longest" in 'completeopt' is ignored.
Note that the after calling this function you need to avoid inserting anything that would cause completion to stop.
The match can be selected with CTRL-N and CTRL-P as usual with Insert mode completion. The popup menu will appear if specified, see ins-completion-menu.
Unlike with other ins-completion modes, the CTRL-N and CTRL-P keys can be mapped while this completion is active.
For example, to make CTRL-N move the selection without inserting the match:

```
inoremap <expr> <C-N> complete_info().mode ==# 'eval'
                        \ ? '<Down>' : '<C-N>'
```

Example:

```
inoremap <F5> <C-R>=ListMonths()<CR>

func ListMonths()
  call complete(col('.'), ['January', 'February', 'March',
        \ 'April', 'May', 'June', 'July', 'August',
        \ 'September', 'October', 'November', 'December'])
  return ''
endfunc
```

This isn't very useful, but it shows how it works. Note that an empty string is returned to avoid a zero being inserted.

Parameters:
- {startcol} (integer)

- {matches} (any[])

complete_add({expr}) complete_add()

Add {expr} to the list of matches. Only to be used by the function specified with the 'completefunc' option.
Returns 0 for failure (empty string or out of memory), 1 when the match was added, 2 when the match was already in the list.
See complete-functions for an explanation of {expr}. It is the same as one item in the list that 'omnifunc' would return.

Parameters:
- {expr} (any)

Return:
(0|1|2)

complete_check() complete_check()

Check for a key typed while looking for completion matches.

This is to be used when looking for matches takes some time.
Returns TRUE when searching for matches is to be aborted,
zero otherwise.
Only to be used by the function specified with the
'completefunc' option.

Return:

(0|1)

complete_info([{what}]) complete_info()

Returns a Dictionary with information about Insert mode
completion. See ins-completion.
The items are:

auto	TRUE when Vim started this completion by itself, which is what 'autocomplete' does, and FALSE when a key asked for it, such as i_CTRL-X_CTRL-O. A complete-functions function can read this to tell the two apart. Returned only when asked for in {what}.
completed	Return a dictionary containing the entries of the currently selected index item.
items	List of all completion candidates. Each item is a dictionary containing the entries "word", "abbr", "menu", "kind", "info", "abbr_hlgroup", "kind_hlgroup" and "user_data". The highlight group entries hold the name that the item was added with, or an empty string. "equal", "preselect" and "commit_chars" are included only for items that set them. See complete-items.
matches	Same as "items", but only returns items that are matching current query. If both "matches" and "items" are in "what", the returned list will still be named "items", but each item will have an additional "match" field.
mode	Current completion mode name string. See complete_info_mode for the values.
preinserted_text	The actual text that is pre-inserted, see preinserted().
pum_visible	TRUE if popup menu is visible. See pumvisible().
selected	Selected item index. First index is zero. Index is -1 if no item is selected (showing typed text only, or the last completion after no item is selected when using the <Up> or <Down> keys)
preview_winid	Info floating preview window id.
preview_bufnr	Info floating preview buffer id.

complete_info_mode

mode values are:

""	Not in completion mode
"keyword"	Keyword completion i_CTRL-X_CTRL-N
"ctrl_x"	Just pressed CTRL-X i_CTRL-X
"scroll"	Scrolling with i_CTRL-X_CTRL-E or i_CTRL-X_CTRL-Y
"whole_line"	Whole lines i_CTRL-X_CTRL-L
"files"	File names i_CTRL-X_CTRL-F
"tags"	Tags i_CTRL-X_CTRL-]
"path_defines"	Definition completion i_CTRL-X_CTRL-D
"path_patterns"	Include completion i_CTRL-X_CTRL-I
"dictionary"	Dictionary i_CTRL-X_CTRL-K
"thesaurus"	Thesaurus i_CTRL-X_CTRL-T
"cmdline"	Vim Command line i_CTRL-X_CTRL-V
"function"	User defined completion i_CTRL-X_CTRL-U
"omni"	Omni completion i_CTRL-X_CTRL-O
"spell"	Spelling suggestions i_CTRL-X_s
"eval"	complete() completion
"register"	Words from registers i_CTRL-X_CTRL-R
"unknown"	Other internal modes

If the optional {what} list argument is supplied, then only
the items listed in {what} are returned. Unsupported items in
{what} are silently ignored.

To get the position and size of the popup menu, see
pum_getpos(). It's also available in v:event during the
CompleteChanged event.

Returns an empty Dictionary on error.

Examples:

```
" Get all items
call complete_info()
" Get only 'mode'
call complete_info(['mode'])
" Get only 'mode' and 'pum_visible'
call complete_info(['mode', 'pum_visible'])
```

Parameters:
- {what} (any[]?)

Return:
(table)

confirm({msg} [, {choices} [, {default} [, {type}]]]) confirm()

confirm() offers the user a dialog, from which a choice can be made. It returns the number of the choice. For the first choice this is 1.

{msg} is displayed in a dialog with {choices} as the alternatives. When {choices} is missing or empty, "&OK" is used (and translated).
{msg} is a String, use '\n' to include a newline. Only on some systems the string is wrapped when it doesn't fit.

{choices} is a String, with the individual choices separated by '\n', e.g.

```
confirm("Save changes?", "&Yes\n&No\n&Cancel")
```

The letter after the '&' is the shortcut key for that choice. Thus you can type 'c' to select "Cancel". The shortcut does not need to be the first letter:

```
confirm("file has been modified", "&Save\nSave &All")
```

For the console, the first letter of each choice is used as the default shortcut key. Case is ignored.

The optional {type} String argument gives the type of dialog. It can be one of these values: "Error", "Question", "Info", "Warning" or "Generic". Only the first character is relevant. When {type} is omitted, "Generic" is used.

The optional {type} argument gives the type of dialog. This is only used for the icon of the Win32 GUI. It can be one of these values: "Error", "Question", "Info", "Warning" or "Generic". Only the first character is relevant. When {type} is omitted, "Generic" is used.

If the user aborts the dialog by pressing <Esc>, CTRL-C, or another valid interrupt key, confirm() returns 0.

An example:

```
let choice = confirm("What do you want?",
                  \ "&Apples\n&Oranges\n&Bananas", 2)
if choice == 0
     echo "make up your mind!"
elseif choice == 3
     echo "tasteful"
else
     echo "I prefer bananas myself."
endif
```

In a GUI dialog, buttons are used. The layout of the buttons depends on the 'v' flag in 'guioptions'. If it is included, the buttons are always put vertically. Otherwise, confirm() tries to put the buttons in one horizontal line. If they don't fit, a vertical layout is used anyway. For some systems the horizontal layout is always used.

Parameters:
- {msg} (string)
- {choices} (string?)
- {default} (integer?)
- {type} (string?)

Return:
(integer)

copy({expr}) copy()

Lua: Prefer vim.deepcopy(); deeper than Vimscript copy().

Make a copy of {expr}. For Numbers and Strings this isn't different from using {expr} directly.
When {expr} is a List a shallow copy is created. This means that the original List can be changed without changing the copy, and vice versa. But the items are identical, thus changing an item changes the contents of both Lists.
A Dictionary is copied in a similar way as a List.
Also see deepcopy().

Parameters:
- {expr} (T)

Return:
(T)

cos({expr}) cos()

Lua: Prefer math.cos().

Return the cosine of {expr}, measured in radians, as a Float.
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo cos(100)
```

0.862319

```
echo cos(-4.01)
```

-0.646043

Parameters:
- {expr} (number)

Return:
(number)

cosh({expr}) cosh()

Lua: Prefer math.cosh().

Return the hyperbolic cosine of {expr} as a Float in the range
[1, inf].
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo cosh(0.5)
```

1.127626

```
echo cosh(-0.5)
```

1.127626

Parameters:
- {expr} (number)

Return:
(number)

count({comp}, {expr} [, {ic} [, {start}]]) count() E706

Return the number of times an item with value {expr} appears
in String, List or Dictionary {comp}.

If {start} is given then start with the item with this index.
{start} can only be used with a List.

When {ic} is given and it's TRUE then case is ignored.

When {comp} is a string then the number of not overlapping
occurrences of {expr} is returned. Zero is returned when
{expr} is an empty string.

Parameters:
- {comp} (string|table|any[])
- {expr} (any)
- {ic} (boolean?)
- {start} (integer?)

Return:
(integer)

cursor({lnum}, {col} [, {off}]) cursor()

cursor({list})

Lua: Prefer nvim_win_set_cursor() with {lnum, col - 1};
off, curswant, and failure semantics differ.

Positions the cursor at the column (byte count) {col} in the
line {lnum}. The first column is one.

When there is one argument {list} this is used as a List
with two, three or four item:

[{lnum}, {col}]
[{lnum}, {col}, {off}]
[{lnum}, {col}, {off}, {curswant}]
This is like the return value of getpos() or getcurpos(), but without the first item.

To position the cursor using {col} as the character count, use setcursorcharpos().

Does not change the jumplist.
{lnum} is used like with getline(), except that if {lnum} is zero, the cursor will stay in the current line.
If {lnum} is greater than the number of lines in the buffer, the cursor will be positioned at the last line in the buffer.
If {col} is greater than the number of bytes in the line, the cursor will be positioned at the last character in the line.
If {col} is zero, the cursor will stay in the current column.
If {curswant} is given it is used to set the preferred column for vertical movement. Otherwise {col} is used.

When 'virtualedit' is used {off} specifies the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character.
Returns 0 when the position could be set, -1 otherwise.

Parameters:
- {list} (integer[])

Return:
(any)

debugbreak({pid}) debugbreak()

Lua: Prefer uv.kill() with "sigtrap" (or "sigint" outside MS-Windows); exact semantics differ.

Specifically used to interrupt a program being debugged. It will cause process {pid} to get a SIGTRAP. Behavior for other processes is undefined. See terminal-debug.
(Sends a SIGINT to a process {pid} other than MS-Windows)

Returns TRUE if successfully interrupted the program.
Otherwise returns FALSE.

Parameters:
- {pid} (integer)

Return:
(any)

deepcopy({expr} [, {noref}]) deepcopy() E698

Lua: Prefer vim.deepcopy().

Make a copy of {expr}. For Numbers and Strings this isn't different from using {expr} directly.
When {expr} is a List a full copy is created. This means that the original List can be changed without changing the copy, and vice versa. When an item is a List, a copy for it is made, recursively. Thus changing an item in the copy does not change the contents of the original List.

When {noref} is omitted or zero a contained List or Dictionary is only copied once. All references point to this single copy. With {noref} set to 1 every occurrence of a List or Dictionary results in a new copy. This also means that a cyclic reference causes deepcopy() to fail.

E724

Nesting is possible up to 100 levels. When there is an item that refers back to a higher level making a deep copy with {noref} set to 1 will fail.
Also see copy().

Parameters:
- {expr} (T)
- {noref} (boolean?)

Return:
(T)

delete({fname} [, {flags}]) delete()

Lua: Prefer vim.fs.rm().

Without {flags} or with {flags} empty: Deletes the file by the name {fname}.

This also works when {fname} is a symbolic link. The symbolic link itself is deleted, not what it points to.

When {flags} is "d": Deletes the directory by the name {fname}. This fails when directory {fname} is not empty.

When {flags} is "rf": Deletes the directory by the name
{fname} and everything in it, recursively. BE CAREFUL!
Note: on MS-Windows it is not possible to delete a directory
that is being used.

The result is a Number, which is 0/false if the delete
operation was successful and -1/true when the deletion failed
or partly failed.

Parameters:

- {fname} (string)
- {flags} (string?)

Return:

(integer)

deletebufline({buf}, {first} [, {last}]) deletebufline()

Lua: Prefer nvim_buf_set_lines().

Delete lines {first} to {last} (inclusive) from buffer {buf}.
If {last} is omitted then delete line {first} only.
On success 0 is returned, on failure 1 is returned.

This function works only for loaded buffers. First call
bufload() if needed.

For the use of {buf}, see bufname() above.

{first} and {last} are used like with getline(). Note that
when using line() this refers to the current buffer. Use "$"
to refer to the last line in buffer {buf}.

Parameters:

- {buf} (integer|string)
- {first} (integer|string)
- {last} (integer|string?)

Return:

(any)

dictwatcheradd({dict}, {pattern}, {callback}) dictwatcheradd()

Adds a watcher to a dictionary. A dictionary watcher is
identified by three components:

- A dictionary({dict});
- A key pattern({pattern}).
- A function({callback}).

After this is called, every change on {dict} and on keys
matching {pattern} will result in {callback} being invoked.

For example, to watch all global variables:

```
silent! call dictwatcherdel(g:, '*', 'OnDictChanged')
function! OnDictChanged(d,k,z)
  echomsg string(a:k) string(a:z)
endfunction
call dictwatcheradd(g:, '*', 'OnDictChanged')
```

For now {pattern} only accepts very simple patterns that can
contain a "*" at the end of the string, in which case it will
match every key that begins with the substring before the "*".
That means if "*" is not the last character of {pattern}, only
keys that are exactly equal as {pattern} will be matched.

The {callback} receives three arguments:

- The dictionary being watched.
- The key which changed.
- A dictionary containing the new and old values for the key.

The type of change can be determined by examining the keys
present on the third argument:

- If contains both old and new, the key was updated.

- If it contains only new, the key was added.

- If it contains only old, the key was deleted.

This function can be used by plugins to implement options with validation and parsing logic.

Parameters:
- {dict} (table)

- {pattern} (string)

- {callback} (function)

Return:
(any)

dictwatcherdel({dict}, {pattern}, {callback}) dictwatcherdel()

Removes a watcher added with dictwatcheradd(). All three arguments must match the ones passed to dictwatcheradd() in order for the watcher to be successfully deleted.

Parameters:
- {dict} (any)

- {pattern} (string)

- {callback} (function)

Return:
(any)

did_filetype() did_filetype()

Returns TRUE when autocommands are being executed and the FileType event triggered at least once for a buffer with a non-empty 'filetype'. Can be used to avoid triggering the FileType event again in the ftdetect scripts. FileType Returns FALSE when :setf FALLBACK was used.

When editing another file, the counter is reset, thus this really checks if the FileType event has been triggered for the current buffer. This allows an autocommand that starts editing another buffer to set 'filetype' and load a syntax file.

Attributes:
api-fast

Return:
(integer)

diff_filler({lnum}) diff_filler()

Returns the number of filler lines above line {lnum}.
These are the lines that were inserted at this point in another diff'ed window. These filler lines are shown in the display but don't exist in the buffer.
{lnum} is used like with getline(). Thus "." is the current line, "'m" mark m, etc.

To get the filler lines after the last buffer line, use:

```
echo diff_filler(line('$')+1)
```

Returns 0 if the current window is not in diff mode or filler lines have been disabled using 'diffopt'.

Parameters:
- {lnum} (integer|string)

Return:
(integer)

diff_hlID({lnum}, {col}) diff_hlID()

Returns the highlight ID for diff mode at line {lnum} column {col} (byte index). When the current line does not have a diff change zero is returned.
{lnum} is used like with getline(). Thus "." is the current line, "'m" mark m, etc.
{col} is 1 for the leftmost column, {lnum} is 1 for the first line.

The highlight ID can be used with synIDattr() to obtain
syntax information about the highlighting.

Parameters:
- {lnum} (integer|string)

- {col} (integer)

Return:
(any)

digraph_get({chars}) digraph_get() E1214

Return the digraph of {chars}. This should be a string with exactly two characters. If {chars} are not just two characters, or the digraph of {chars} does not exist, an error is given and an empty string is returned.

Also see digraph_getlist().

Examples:

```
" Get a built-in digraph
echo digraph_get('00')          " Returns '∞'

" Get a user-defined digraph
call digraph_set('aa', '□')
echo digraph_get('aa')          " Returns '□'
```

Parameters:
- {chars} (string)

Return:
(string)

digraph_getlist([{listall}]) digraph_getlist()

Return a list of digraphs. If the {listall} argument is given and it is TRUE, return all digraphs, including the default digraphs. Otherwise, return only user-defined digraphs.

Also see digraph_get().

Examples:

```
" Get user-defined digraphs
echo digraph_getlist()

" Get all the digraphs, including default digraphs
echo digraph_getlist(1)
```

Parameters:
- {listall} (boolean?)

Return:
(string[][])

digraph_set({chars}, {digraph}) digraph_set()

Add digraph {chars} to the list. {chars} must be a string with two characters. {digraph} is a string with one UTF-8 encoded character. E1215
Be careful, composing characters are NOT ignored. This function is similar to :digraphs command, but useful to add digraphs start with a white space.

The function result is v:true if digraph is registered. If this fails an error message is given and v:false is returned.

If you want to define multiple digraphs at once, you can use digraph_setlist().

Example:

```
call digraph_set('  ', '□')
```

Parameters:
- {chars} (string)

- {digraph} (string)

Return:
(any)

digraph_setlist({digraphlist}) digraph_setlist()

Similar to digraph_set() but this function can add multiple digraphs at once. {digraphlist} is a list composed of lists, where each list contains two strings with {chars} and

{digraph} as in digraph_set(). E1216
Example:

```
call digraph_setlist([['aa', '□'], ['ii', '□']])
```

It is similar to the following:

```
for [chars, digraph] in [['aa', '□'], ['ii', '□']]
      call digraph_set(chars, digraph)
endfor
```

Except that the function returns after the first error,
following digraphs will not be added.

Parameters:
- {digraphlist} (table<integer,string[]>)

Return:
(any)

empty({expr}) empty()

Lua: Prefer plain Lua emptiness checks, or vim.tbl_isempty()
for tables.

Return the Number 1 if {expr} is empty, zero otherwise.
- A List or Dictionary is empty when it does not have any
  items.
- A String is empty when its length is zero.
- A Number and Float are empty when their value is zero.
- v:false and v:null are empty, v:true is not.
- A Blob is empty when its length is zero.

Parameters:
- {expr} (any)

Return:
(integer)

environ() environ()

Lua: Prefer uv.os_environ() for the full environment table;
vim.env for keyed access.

Return all of environment variables as dictionary. You can
check if an environment variable exists like this:

```
echo has_key(environ(), 'HOME')
```

Note that the variable name may be CamelCase; to ignore case
use this:

```
echo index(keys(environ()), 'HOME', 0, 1) != -1
```

Attributes:
api-fast

Return:
(any)

escape({string}, {chars}) escape()

Escape the characters in {chars} that occur in {string} with a
backslash. Example:

```
echo escape('c:\program files\vim', ' \')
```

results in:

```
c:\\program\ files\\vim
```

Also see shellescape() and fnameescape().

Attributes:
api-fast

Parameters:
- {string} (string)
- {chars} (string)

Return:
(string)

eval({string}) eval()

Evaluate {string} and return the result. Especially useful to turn the result of string() back into the original value. This works for Numbers, Floats, Strings, Blobs and composites of them. Also works for Funcrefs that refer to existing functions.

Parameters:
- {string} (string)

Return:
(any)

eventhandler() eventhandler()

Returns 1 when inside an event handler. That is that Vim got interrupted while waiting for the user to type a character, e.g., when dropping a file on Vim. This means interactive commands cannot be used. Otherwise zero is returned.

Return:
(any)

executable({expr}) executable()

This function checks if an executable with the name {expr} exists. {expr} must be the name of the program without any arguments.

executable() uses the value of $PATH and/or the normal searchpath for programs.

PATHEXT

On MS-Windows the ".exe", ".bat", etc. can optionally be included. Then the extensions in $PATHEXT are tried. Thus if "foo.exe" does not exist, "foo.exe.bat" can be found. If $PATHEXT is not set then ".com;.exe;.bat;.cmd" is used. A dot by itself can be used in $PATHEXT to try using the name without an extension. When 'shell' looks like a Unix shell, then the name is also tried without adding an extension. On MS-Windows it only checks if the file exists and is not a directory, not if it's really executable.

On MS-Windows an executable in the same directory as the Vim executable is always found (it's added to $PATH at startup).

$NoDefaultCurrentDirectoryInExePath

On MS-Windows when using cmd.exe as 'shell' an executable in Vim's current working directory is also normally found, which can be disabled by setting the $NoDefaultCurrentDirectoryInExePath environment variable. This variable is always set by Vim when executing external commands (e.g., via :!, :make, or system()) for security reasons.

The result is a Number:
1 exists
0 does not exist
exepath() can be used to get the full path of an executable.

Attributes:
api-fast

Parameters:
- {expr} (string)

Return:
(0|1)

execute({command} [, {silent}]) execute()

Lua: Prefer nvim_exec() or vim.cmd().

Execute {command} and capture its output.
If {command} is a String, returns {command} output.
If {command} is a List, returns concatenated outputs.
Line continuations in {command} are not recognized.
Examples:

```
echo execute('echon "foo"')
```

foo

```
echo execute(['echon "foo"', 'echon "bar"'])
```

foobar

The optional {silent} argument can have these values:
"" no :silent used
"silent" :silent used

"silent!" :silent! used
The default is "silent". Note that with "silent!", unlike
:redir, error messages are dropped.

To get a list of lines use split() on the result:

```
execute('args')->split("\n")
```

This function is not available in the sandbox.
Note: If nested, an outer execute() will not observe output of
the inner calls.
Note: Text attributes (highlights) are not captured.
To execute a command in another window than the current one
use win_execute().

Parameters:
- {command} (string|string[])

- {silent} (''|'silent'|'silent!'?)

Return:
(string)

exepath({expr}) exepath()

Returns the full path of {expr} if it is an executable and
given as a (partial or full) path or is found in $PATH.
Returns empty string otherwise.
If {expr} starts with "./" the current-directory is used.

Attributes:
api-fast

Parameters:
- {expr} (string)

Return:
(string)

exists({expr}) exists()

Checks whether the expression {expr} is defined.
Returns TRUE if {expr} is defined, zero otherwise.

For checking for a supported feature use has().
For checking if a file exists use filereadable().

The {expr} argument is a string, which contains one of these:

varname	internal variable (see internal-variables). Also works
dict.key	for curly-braces-names, Dictionary entries, List items, etc.
list[i]	Beware that evaluating an index may cause an error message for an invalid expression. E.g.:

```
let l = [1, 2, 3]
echo exists("l[5]")
```

0

```
echo exists("l[xx]")
```

E121: Undefined variable: xx
0

&option-name	Vim option (only checks if it exists, not if it really works)
+option-name	Vim option that works.
$ENVNAME	environment variable (could also be done by comparing with an empty string)
*funcname	built-in function (see functions) or user defined function (see user-function). Also works for a variable that is a Funcref.
:cmdname	Ex command: built-in command, user command or command modifier :command. Returns: 1 for match with start of a command 2 full match with a command 3 matches several user commands To check for a supported command always check the return value to be 2.
:2match	The :2match command.
:3match	The :3match command (but you probably should not use it, it is reserved for internal usage)
#event	autocommand defined for this event
#event#pattern	autocommand defined for this event and pattern (the pattern is taken

literally and compared to the
autocommand patterns character by
character)
#group autocommand group exists
#group#event autocommand defined for this group and
event.
#group#event#pattern
autocommand defined for this group,
event and pattern.
##event autocommand for this event is
supported.

Examples:

```
echo exists("&mouse")
echo exists("$HOSTNAME")
echo exists("*strftime")
echo exists("*s:MyFunc")
echo exists("*MyFunc")
echo exists("*v:lua.Func")
echo exists("bufcount")
echo exists(":Make")
echo exists("#CursorHold")
echo exists("#BufReadPre#*.gz")
echo exists("#filetypeindent")
echo exists("#filetypeindent#FileType")
echo exists("#filetypeindent#FileType#*")
echo exists("##ColorScheme")
```

There must be no space between the symbol (&/$/*/#) and the
name.
There must be no extra characters after the name, although in
a few cases this is ignored. That may become stricter in the
future, thus don't count on it!
Working example:

```
echo exists(":make")
```

NOT working example:

```
echo exists(":make install")
```

Note that the argument must be a string, not the name of the
variable itself. For example:

```
echo exists(bufcount)
```

This doesn't check for existence of the "bufcount" variable,
but gets the value of "bufcount", and checks if that exists.

Parameters:
- {expr} (string)

Return:
(0|1)

exp({expr}) exp()

Lua: Prefer math.exp().

Return the exponential of {expr} as a Float in the range
[0, inf].
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo exp(2)
```

7.389056

```
echo exp(-1)
```

0.367879

Parameters:
- {expr} (number)

Return:
(any)

expand({string} [, {nosuf} [, {list}]]) expand()

Expand wildcards and the following special keywords in
{string}. 'wildignorecase' applies.

If {list} is given and it is TRUE, a List will be returned.
Otherwise the result is a String and when there are several
matches, they are separated by <NL> characters.

If the expansion fails, the result is an empty string. A name
for a non-existing file is not included, unless {string} does

not start with '%', '#' or '<', see below.

When {string} starts with '%', '#' or '<', the expansion is done like for the cmdline-special variables with their associated modifiers. Here is a short overview:

%	Current file name
#	Alternate file name
#n	Alternate file name n
<cfile>	File name under the cursor
<afile>	Autocmd file name
<abuf>	Autocmd buffer number (as a String!)
<amatch>	Autocmd matched name
<cexpr>	C expression under the cursor
<sfile>	**Deprecated**, use <script> or <stack>
<slnum>	Sourced script line number or function line number
<sflnum>	Script file line number, also when in a function
<SID>	"<SNR>123_" where "123" is the current script ID <SID>
<script>	Sourced script file, or script file where the current function was defined. Lua: see lua-script-location.
<stack>	Call stack
<cword>	Word under the cursor
<cWORD>	WORD under the cursor
<client>	The {clientid} of the last received message

Modifiers:

:p	Expand to full path
:h	Head (last path component removed)
:t	Tail (last path component only)
:r	Root (one extension removed)
:e	Extension only

More modifiers are supported, for the full list see filename-modifiers.

Example:

```
let &tags = expand("%:p:h") .. "/tags"
```

Note that when expanding a string that starts with '%', '#' or '<', any following text is ignored. This does NOT work:

```
let doesntwork = expand("%:h.bak")
```

Use this:

```
let doeswork = expand("%:h") .. ".bak"
```

Also note that expanding "<cfile>" and others only returns the referenced file name without further expansion. If "<cfile>" is "~/.cshrc", you need to do another expand() to have the "~/" expanded into the path of the home directory:

```
echo expand(expand("<cfile>"))
```

There cannot be white space between the variables and the following modifier. The fnamemodify() function can be used to modify normal file names.

When using '%' or '#', and the current or alternate file name is not defined, an empty string is used. Using "%:p" in a buffer with no name, results in the current directory, with a '/' added.
When 'verbose' is set then expanding '%', '#' and <> items will result in an error message if the argument cannot be expanded.

When {string} does not start with '%', '#' or '<', it is expanded like a file name is expanded on the command line. 'suffixes' and 'wildignore' are used, unless the optional {nosuf} argument is given and it is TRUE.
Names for non-existing files are included. The "**" item can be used to search in a directory tree. For example, to find all "README" files in the current directory and below:

```
echo expand("**/README")
```

expand() can also be used to expand variables and environment variables that are only known in a shell. But this can be slow, because a shell may be used to do the expansion. See expr-env-expand.
The expanded variable is still handled like a list of file names. When an environment variable cannot be expanded, it is left unchanged. Thus ":echo expand('$FOOBAR')" results in "$FOOBAR".

See glob() for finding existing files. See system() for getting the raw output of an external command.

Parameters:

- {string} (string)
- {nosuf} (boolean?)
- {list} (nil|false?)

Return:
(string)

expandcmd({string} [, {options}]) expandcmd()

Expand special items in String {string} like what is done for an Ex command such as :edit. This expands special keywords, like with expand(), and environment variables, anywhere in {string}. "~user" and "~/path" are only expanded at the start.
The expansion is done in two steps: the special keywords are evaluated first, then "~" and environment variables are expanded in the result. Thus expand('%:~') keeps the "~", while expandcmd('%:~') returns the full path.

The following items are supported in the {options} Dict argument:

errmsg	If set to TRUE, error messages are displayed if an error is encountered during expansion. By default, error messages are not displayed.

Returns the expanded string. If an error is encountered during expansion, the unmodified {string} is returned.

Example:

```
echo expandcmd('make %<.o')
```

```
make /path/runtime/doc/builtin.o
```

```
echo expandcmd('make %<.o', {'errmsg': v:true})
```

Parameters:
- {string} (string)
- {options} (table?)

Return:
(any)

extend({expr1}, {expr2} [, {expr3}]) extend()

Lua: Prefer vim.list_extend() for lists, or vim.tbl_extend() and vim.tbl_deep_extend() for dicts; insertion and keep/force/error behavior differ.

{expr1} and {expr2} must be both Lists or both Dictionaries.

If they are Lists: Append {expr2} to {expr1}.
If {expr3} is given insert the items of {expr2} before the item with index {expr3} in {expr1}. When {expr3} is zero insert before the first item. When {expr3} is equal to len({expr1}) then {expr2} is appended.
Examples:

```
echo sort(extend(mylist, [7, 5]))
call extend(mylist, [2, 3], 1)
```

When {expr1} is the same List as {expr2} then the number of items copied is equal to the original length of the List.
E.g., when {expr3} is 1 you get N new copies of the first item (where N is the original length of the List).
Use add() to concatenate one item to a list. To concatenate two lists into a new list use the + operator:

```
let newlist = [1, 2, 3] + [4, 5]
```

If they are Dictionaries:
Add all entries from {expr2} to {expr1}.
If a key exists in both {expr1} and {expr2} then {expr3} is used to decide what to do:
{expr3} = "keep": keep the value of {expr1}
{expr3} = "force": use the value of {expr2}
{expr3} = "error": give an error message E737

When {expr3} is omitted then "force" is assumed.

{expr1} is changed when {expr2} is not empty. If necessary make a copy of {expr1} first or use extendnew() to return a new List/Dictionary.
{expr2} remains unchanged.

When {expr1} is locked and {expr2} is not empty the operation
fails.
Returns {expr1}. Returns 0 on error.

Parameters:

- {expr1} (table)
- {expr2} (table)
- {expr3} (table?)

Return:

(any)

extendnew({expr1}, {expr2} [, {expr3}]) extendnew()

Lua: Prefer vim.list_extend() on a copy for lists, or
vim.tbl_extend() and vim.tbl_deep_extend() for dicts;
insertion and keep/force/error behavior differ.

Like extend() but instead of adding items to {expr1} a new
List or Dictionary is created and returned. {expr1} remains
unchanged.

Parameters:

- {expr1} (table)
- {expr2} (table)
- {expr3} (table?)

Return:

(any)

feedkeys({string} [, {mode}]) feedkeys()

Lua: Prefer nvim_feedkeys().

Characters in {string} are queued for processing as if they
come from a mapping or were typed by the user.

By default the string is added to the end of the typeahead
buffer, thus if a mapping is still being executed the
characters come after them. Use the 'i' flag to insert before
other characters, they will be executed next, before any
characters from a mapping.

The function does not wait for processing of keys contained in
{string}.

To include special keys into {string}, use double-quotes
and "\..." notation expr-quote. For example,
feedkeys("\<CR>") simulates pressing of the <Enter> key. But
feedkeys('\<CR>') pushes 5 characters.
The <Ignore> keycode may be used to exit the
wait-for-character without doing anything.

{mode} is a String, which can contain these character flags:
'm'   Remap keys. This is default. If {mode} is absent,
        keys are remapped.
'n'   Do not remap keys.
't'   Handle keys as if typed; otherwise they are handled as
        if coming from a mapping. This matters for undo,
        opening folds, etc.
'L'   Lowlevel input. Other flags are not used.
'i'   Insert the string instead of appending (see above).
'x'   Execute commands until typeahead is empty. This is
        similar to using ":normal!". You can call feedkeys()
        several times without 'x' and then one time with 'x'
        (possibly with an empty {string}) to execute all the
        typeahead. Note that when Vim ends in Insert mode it
        will behave as if <Esc> is typed, to avoid getting
        stuck, waiting for a character to be typed before the
        script continues.
        Note that if you manage to call feedkeys() while
        executing commands, thus calling it recursively, then
        all typeahead will be consumed by the last call.
'!'   When used with 'x' will not end Insert mode. Can be
        used in a test when a timer is set to exit Insert mode
        a little later. Useful for testing CursorHoldI.

Return value is always 0.

Parameters:

- {string} (string)
- {mode} (string?)

Return:
(any)

filecopy({from}, {to}) filecopy()

Lua: Prefer uv.fs_copyfile() with { excl = true }; return semantics differ.

Copy the file pointed to by the name {from} to {to}. The result is a Number, which is TRUE if the file was copied successfully, and FALSE when it failed.
If a file with name {to} already exists, it will fail.
Note that it does not handle directories (yet).

This function is not available in the sandbox.

Parameters:
- {from} (string)

- {to} (string)

Return:
(0|1)

filereadable({file}) filereadable()

Lua: Prefer uv.fs_access() with "R" and uv.fs_stat() to exclude directories.

Returns TRUE if {file} exists, can be read, and is not a directory, else FALSE.

{file} is any expression, which is used as a String. If you don't care about the file being readable you can use glob().

{file} is used as-is, you may want to expand wildcards first:

```
echo filereadable('~/.vimrc')
```

```
0
```

```
echo filereadable(expand('~/.vimrc'))
```

```
1
```

Attributes:
api-fast

Parameters:
- {file} (string)

Return:
(0|1)

filewritable({file}) filewritable()

Lua: Prefer uv.fs_access() with "W" and uv.fs_stat() if you need Vim's 2 return for directories.

Checks whether a file with the name {file} exists and can be written. Returns 1 if so. If {file} doesn't exist, or is not writable, the result is 0. If {file} is a directory, and we can write to it, the result is 2.

Attributes:
api-fast

Parameters:
- {file} (string)

Return:
(0|1)

filter({expr1}, {expr2}) filter()

Lua: Prefer vim.tbl_filter() for lists; dicts, strings, and blobs differ.

{expr1} must be a List, String, Blob or Dictionary.
For each item in {expr1} evaluate {expr2} and when the result is zero or false remove the item from the List or Dictionary. Similarly for each byte in a Blob and each character in a String.

{expr2} must be a string or Funcref.

If {expr2} is a string, inside {expr2} v:val has the value of the current item. For a Dictionary v:key has the key of the current item and for a List v:key has the index of the current item. For a Blob v:key has the index of the current byte. For a String v:key has the index of the current character.
Examples:

```
call filter(mylist, 'v:val !~ "OLD"')
```

Removes the items where "OLD" appears.

```
call filter(mydict, 'v:key >= 8')
```

Removes the items with a key below 8.

```
call filter(var, 0)
```

Removes all the items, thus clears the List or Dictionary.

Note that {expr2} is the result of expression and is then used as an expression again. Often it is good to use a literal-string to avoid having to double backslashes.

If {expr2} is a Funcref it must take two arguments:

1. the key or the index of the current item.
2. the value of the current item.

The function must return TRUE if the item should be kept. Example that keeps the odd items of a list:

```
func Odd(idx, val)
  return a:idx % 2 == 1
endfunc
call filter(mylist, function('Odd'))
```

It is shorter when using a lambda:

```
call filter(myList, {idx, val -> idx * val <= 42})
```

If you do not use "val" you can leave it out:

```
call filter(myList, {idx -> idx % 2 == 1})
```

For a List and a Dictionary the operation is done in-place. If you want it to remain unmodified make a copy first:

```
let l = filter(copy(mylist), 'v:val =~ "KEEP"')
```

Returns {expr1}, the List or Dictionary that was filtered, or a new Blob or String.
When an error is encountered while evaluating {expr2} no further items in {expr1} are processed.
When {expr2} is a Funcref errors inside a function are ignored, unless it was defined with the "abort" flag.

Parameters:

- {expr1} (string|table)
- {expr2} (string|function)

Return:

(any)

finddir({name} [, {path} [, {count}]]) finddir()

Lua: Prefer vim.fs.find() with type = 'directory'; path, count, and return semantics differ.

Find directory {name} in {path}. Supports both downwards and upwards recursive directory searches. See file-searching for the syntax of {path}.

Returns the path of the first found match. When the found directory is below the current directory a relative path is returned. Otherwise a full path is returned.
If {path} is omitted or empty then 'path' is used.

If the optional {count} is given, find {count}'s occurrence of {name} in {path} instead of the first one.
When {count} is negative return all the matches in a List.

Returns an empty string if the directory is not found.

This is quite similar to the ex-command :find.

Parameters:

- {name} (string)
- {path} (string?)
- {count} (integer?)

Return:
(string|string[])

findfile({name} [, {path} [, {count}]]) findfile()

Lua: Prefer vim.fs.find(); path, count, return semantics, and 'suffixesadd' handling differ.

Just like finddir(), but find a file instead of a directory. Uses 'suffixesadd'. Example:

```
echo findfile("tags.vim", ".;")
```

Searches from the directory of the current file upwards until it finds the file "tags.vim".

Parameters:
- {name} (string)
- {path} (string?)
- {count} (integer?)

Return:
(string|string[])

flatten({list} [, {maxdepth}]) flatten()

Lua: Prefer vim.iter(list):flatten():totable() for a new flattened list; in-place updates and maxdepth differ.

Flatten {list} up to {maxdepth} levels. Without {maxdepth} the result is a List without nesting, as if {maxdepth} is a very large number. The {list} is changed in place, use flattennew() if you do not want that.

E900

{maxdepth} means how deep in nested lists changes are made. {list} is not modified when {maxdepth} is 0. {maxdepth} must be positive number.

If there is an error the number zero is returned.

Example:

```
echo flatten([1, [2, [3, 4]], 5])
```

```
[1, 2, 3, 4, 5]
```

```
echo flatten([1, [2, [3, 4]], 5], 1)
```

```
[1, 2, [3, 4], 5]
```

Parameters:
- {list} (any[])
- {maxdepth} (integer?)

Return:
(any[]|0)

flattennew({list} [, {maxdepth}]) flattennew()

Lua: Prefer vim.iter(list):flatten():totable() for a new flattened list; maxdepth differs.

Like flatten() but first make a copy of {list}.

Parameters:
- {list} (any[])
- {maxdepth} (integer?)

Return:
(any[]|0)

float2nr({expr}) float2nr()

Lua: Prefer math.modf() (first return value).

Convert {expr} to a Number by omitting the part after the decimal point. {expr} must evaluate to a Float or a Number. Returns 0 if {expr} is not a Float or a Number. When the value of {expr} is out of range for a Number the result is truncated to 0x7fffffff or -0x7fffffff (or when 64-bit Number support is enabled, 0x7fffffffffffffff or

-0x7fffffffffffffff). NaN results in -0x80000000 (or when
64-bit Number support is enabled, -0x8000000000000000).
Examples:

```
echo float2nr(3.95)
```

```
3
```

```
echo float2nr(-23.45)
```

```
-23
```

```
echo float2nr(1.0e100)
```

```
2147483647  (or 9223372036854775807)
```

```
echo float2nr(-1.0e150)
```

```
-2147483647 (or -9223372036854775807)
```

```
echo float2nr(1.0e-100)
```

```
0
```

Parameters:
- {expr} (number)

Return:
(any)

`floor({expr})` floor()

Lua: Prefer math.floor().

Return the largest integral value less than or equal to
{expr} as a Float (round down).
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo floor(1.856)
```

```
1.0
```

```
echo floor(-5.456)
```

```
-6.0
```

```
echo floor(4.0)
```

```
4.0
```

Parameters:
- {expr} (number)

Return:
(any)

`fmod({expr1}, {expr2})` fmod()

Lua: Prefer math.fmod().

Return the remainder of {expr1} / {expr2}, even if the
division is not representable. Returns {expr1} - i * {expr2}
for some integer i such that if {expr2} is non-zero, the
result has the same sign as {expr1} and magnitude less than
the magnitude of {expr2}. If {expr2} is zero, the value
returned is zero. The value returned is a Float.
{expr1} and {expr2} must evaluate to a Float or a Number.
Returns 0.0 if {expr1} or {expr2} is not a Float or a
Number.
Examples:

```
echo fmod(12.33, 1.22)
```

```
0.13
```

```
echo fmod(-12.33, 1.22)
```

```
-0.13
```

Parameters:
- {expr1} (number)

- {expr2} (number)

Return:
(any)

fnameescape({filepath}) fnameescape()

Escapes {filepath} for use as a command argument.

(**Note:** To open a literal filepath programmatically use bufadd(vim.fs.normalize(…)), see open-file.)

All characters that have a special meaning, such as '%' and '|' are escaped with a backslash. For most systems the characters escaped are:

```
\t\n *?[{`$\\%#'\"|!<
```

For systems where a backslash appears in a filename, it depends on the value of 'isfname'. A leading '+' and '>' is also escaped (special after :edit and :write). And a "-" by itself (special after :cd).
Returns an empty string on error.
Example:

```
let fname = '+some str%nge|name'
exe "edit " .. fnameescape(fname)
```

results in executing:

```
edit \+some\ str\%nge\|name
```

Attributes:
api-fast

Parameters:
- {filepath} (string)

Return:
(string)

fnamemodify({fname}, {mods}) fnamemodify()

Lua: Prefer vim.fs.dirname(), vim.fs.basename(), vim.fs.abspath(), and vim.fs.normalize() for common path modifiers; modifier coverage differs.

Modify file name {fname} according to {mods}. {mods} is a string of characters like it is used for file names on the command line. See filename-modifiers.
Example:

```
echo fnamemodify("main.c", ":p:h")
```

results in:

```
/home/user/vim/vim/src
```

If {mods} is empty or an unsupported modifier is used then {fname} is returned.
When {fname} is empty then with {mods} ":h" returns ".", so that :cd can be used with it. This is different from expand('%:h') without a buffer name, which returns an empty string.
Note: Environment variables don't work in {fname}, use expand() first then.

Attributes:
api-fast

Parameters:
- {fname} (string)
- {mods} (string)

Return:
(string)

foldclosed({lnum}) foldclosed()

Returns the first line number of the closed fold containing line {lnum}. If the line {lnum} is not in a closed fold, -1 is returned.
{lnum} is used like with getline(). Thus "." is the current line, "'m" mark m, etc.

Parameters:
- {lnum} (integer|string)

Return:
(integer)

foldclosedend({lnum}) foldclosedend()

Returns the last line number of the closed fold containing

line {lnum}. If the line {lnum} is not in a closed fold,
-1 is returned.
{lnum} is used like with getline(). Thus "." is the current
line, "'m" mark m, etc.

Parameters:
- {lnum} (integer|string)

Return:
(integer)

foldlevel({lnum}) foldlevel()

Returns the fold nesting level of line {lnum} in the current
buffer. {lnum} is used like with getline() ("." is the
current line, "'m" mark m, etc).

For nested folds the deepest level is returned. If there is
no fold at line {lnum}, zero is returned. It doesn't matter
if the folds are open or closed. When used while updating
folds (from 'foldexpr') -1 is returned for lines where folds
are still to be updated and the foldlevel is unknown. As
a special case the level of the previous line is usually
available.

Parameters:
- {lnum} (integer|string)

Return:
(integer)

foldtext() foldtext()

Returns a String, to be displayed for a closed fold. This is
the default function used for the 'foldtext' option and should
only be called from evaluating 'foldtext'. It uses the
v:foldstart, v:foldend and v:folddashes variables.
The returned string looks like this:

```
+-- 45 lines: abcdef
```

The number of leading dashes depends on the foldlevel. The
"45" is the number of lines in the fold. "abcdef" is the text
in the first non-blank line of the fold. Leading white space,
"//" or "/*" and the text from the 'foldmarker' and
'commentstring' options is removed.
When used to draw the actual foldtext, the rest of the line
will be filled with the fold char from the 'fillchars'
setting.
Returns an empty string when there is no fold.

Return:
(string)

foldtextresult({lnum}) foldtextresult()

Returns the text that is displayed for the closed fold at line
{lnum}. Evaluates 'foldtext' in the appropriate context.
When there is no closed fold at {lnum} an empty string is
returned.
{lnum} is used like with getline(). Thus "." is the current
line, "'m" mark m, etc.
Useful when exporting folded text, e.g., to HTML.

Parameters:
- {lnum} (integer|string)

Return:
(string)

foreach({expr1}, {expr2}) foreach()

Lua: Prefer pairs() or ipairs().

{expr1} must be a List, String, Blob or Dictionary.
For each item in {expr1} execute {expr2}. {expr1} is not
modified; its values may be, as with :lockvar 1. E741
See map() and filter() to modify {expr1}.

{expr2} must be a string or Funcref.

If {expr2} is a string, inside {expr2} v:val has the value
of the current item. For a Dictionary v:key has the key
of the current item and for a List v:key has the index of
the current item. For a Blob v:key has the index of the
current byte. For a String v:key has the index of the
current character.
Examples:

```
call foreach(mylist, 'let used[v:val] = v:true')
```

This records the items that are in the {expr1} list.

Note that {expr2} is the result of expression and is then used as a command. Often it is good to use a literal-string to avoid having to double backslashes.

If {expr2} is a Funcref it must take two arguments:

1. the key or the index of the current item.
2. the value of the current item.

With a lambda you don't get an error if it only accepts one argument.
If the function returns a value, it is ignored.

Returns {expr1} in all cases.
When an error is encountered while executing {expr2} no further items in {expr1} are processed.
When {expr2} is a Funcref errors inside a function are ignored, unless it was defined with the "abort" flag.

Parameters:

- {expr1} (string|table)
- {expr2} (string|function)

Return:

(string|table)

fullcommand({name}) fullcommand()

Get the full command name from a short abbreviated command name; see 20.2 for details on command abbreviations.

The string argument {name} may start with a : and can include a [range], these are skipped and not returned. Returns an empty string if a command doesn't exist or if it's ambiguous (for user-defined commands).

Note: Command validation is not performed. Results depend on Vim's internal command-specific identification rules.
Examples:

```
echo [fullcommand('s')]         |" ['substitute']
echo [fullcommand('sub')]               |" ['substitute']
echo [fullcommand(': mark word')]       |" ['mark']
echo [fullcommand(': markword')]        |" ['']
echo [fullcommand('en')]                |" ['endif']
```

Parameters:

- {name} (string)

Return:

(string)

funcref({name} [, {arglist}] [, {dict}]) funcref()

Just like function(), but the returned Funcref will lookup the function by reference, not by name. This matters when the function {name} is redefined later.

Unlike function(), {name} must be an existing user function. It only works for an autoloaded function if it has already been loaded (to avoid mistakenly loading the autoload script when only intending to use the function name, use function() instead). {name} cannot be a builtin function.
Returns 0 on error.

Parameters:

- {name} (string)
- {arglist} (any?)
- {dict} (any?)

Return:

(any)

function({name} [, {arglist}] [, {dict}]) function() partial E700 E923

Return a Funcref variable that refers to function {name}. {name} can be the name of a user defined function or an internal function.

{name} can also be a Funcref or a partial. When it is a partial the dict stored in it will be used and the {dict} argument is not allowed. E.g.:

```
let FuncWithArg = function(dict.Func, [arg])
let Broken = function(dict.Func, [arg], dict)
```

When using the Funcref the function will be found by {name}, also when it was redefined later. Use funcref() to keep the same function.

When {arglist} or {dict} is present this creates a partial. That means the argument list and/or the dictionary is stored in the Funcref and will be used when the Funcref is called.

The arguments are passed to the function in front of other arguments, but after any argument from method. Example:

```
func Callback(arg1, arg2, name)
"...
endfunc
let Partial = function('Callback', ['one', 'two'])
"...
call Partial('name')
```

Invokes the function as with:

```
call Callback('one', 'two', 'name')
```

With a method:

```
func Callback(one, two, three)
"...
endfunc
let Partial = function('Callback', ['two'])
"...
eval 'one'->Partial('three')
```

Invokes the function as with:

```
call Callback('one', 'two', 'three')
```

The function() call can be nested to add more arguments to the Funcref. The extra arguments are appended to the list of arguments. Example:

```
func Callback(arg1, arg2, name)
"...
endfunc
let Func = function('Callback', ['one'])
let Func2 = function(Func, ['two'])
"...
call Func2('name')
```

Invokes the function as with:

```
call Callback('one', 'two', 'name')
```

The Dictionary is only useful when calling a "dict" function. In that case the {dict} is passed in as "self". Example:

```
function Callback() dict
   echo "called for " .. self.name
endfunction
"...
let context = {"name": "example"}
let Func = function('Callback', context)
"...
call Func()     " will echo: called for example
```

The use of function() is not needed when there are no extra arguments, these two are equivalent, if Callback() is defined as context.Callback():

```
let Func = function('Callback', context)
let Func = context.Callback
```

The argument list and the Dictionary can be combined:

```
function Callback(arg1, count) dict
"...
endfunction
let context = {"name": "example"}
let Func = function('Callback', ['one'], context)
"...
call Func(500)
```

Invokes the function as with:

```
call context.Callback('one', 500)
```

Returns 0 on error.

Parameters:

- {name} (string)

- {arglist} (any?)

- {dict} (any?)

Return:
(any)

garbagecollect([{atexit}]) garbagecollect()

Cleanup unused Lists and Dictionaries that have circular references.

There is hardly ever a need to invoke this function, as it is automatically done when Vim runs out of memory or is waiting for the user to press a key after 'updatetime'. Items without circular references are always freed when they become unused. This is useful if you have deleted a very big List and/or Dictionary with circular references in a script that runs for a long time.

When the optional {atexit} argument is one, garbage collection will also be done when exiting Vim, if it wasn't done before. This is useful when checking for memory leaks.

The garbage collection is not done immediately but only when it's safe to perform. This is when waiting for the user to type a character.

Parameters:
- {atexit} (boolean?)

Return:
(any)

get({list}, {idx} [, {default}]) get() get()-list

Get item {idx} from List {list}. When this item is not available return {default}. Return zero when {default} is omitted.

Parameters:
- {list} (any[])

- {idx} (integer)

- {default} (any?)

Return:
(any)

get({blob}, {idx} [, {default}]) get()-blob

Get byte {idx} from Blob {blob}. When this byte is not available return {default}. Return -1 when {default} is omitted.

Parameters:
- {blob} (string)

- {idx} (integer)

- {default} (any?)

Return:
(any)

get({dict}, {key} [, {default}]) get()-dict

Get item with key {key} from Dictionary {dict}. When this item is not available return {default}. Return zero when {default} is omitted. Useful example:

```
let val = get(g:, 'var_name', 'default')
```

This gets the value of g:var_name if it exists, and uses "default" when it does not exist.

Parameters:
- {dict} (table<string,any>)

- {key} (string)

- {default} (any?)

Return:
(any)

get({func}, {what}) get()-func

Get item {what} from Funcref {func}. Possible values for {what} are:

```
"name"    The function name
"func"    The function
"dict"    The dictionary
"args"    The list with arguments
"arity"   A dictionary with information about the number of
          arguments accepted by the function (minus the
          {arglist}) with the following fields:
              required    the number of positional arguments
              optional    the number of optional arguments,
                          in addition to the required ones
              varargs     TRUE if the function accepts a
                          variable number of arguments ...
```

Note: There is no error, if the {arglist} of the Funcref contains more arguments than the Funcref expects, it's not validated.

Returns zero on error.

Parameters:
- {func} (function)

- {what} (string)

Return:
(any)

getbufinfo([{buf}]) getbufinfo()

getbufinfo([{dict}])

Get information about buffers as a List of Dictionaries.

Without an argument information about all the buffers is returned.

When the argument is a Dictionary only the buffers matching the specified criteria are returned. The following keys can be specified in {dict}:

```
buflisted       include only listed buffers.
bufloaded       include only loaded buffers.
bufmodified     include only modified buffers.
```

Otherwise, {buf} specifies a particular buffer to return information for. For the use of {buf}, see bufname() above. If the buffer is found the returned List has one item. Otherwise the result is an empty list.

Each returned List item is a dictionary with the following entries:

```
bufnr           Buffer number.
changed         TRUE if the buffer is modified.
changedtick     Number of changes made to the buffer.
command         TRUE if the buffer belongs to the
                command-line window cmdwin.
hidden          TRUE if the buffer is hidden.
lastused        Timestamp in seconds, like
                localtime(), when the buffer was
                last used.
listed          TRUE if the buffer is listed.
lnum            Line number used for the buffer when
                opened in the current window.
                Only valid if the buffer has been
                displayed in the window in the past.
                If you want the line number of the
                last known cursor position in a given
                window, use line():
```

```
echo line('.', {winid})
```

```
linecount       Number of lines in the buffer (only
                valid when loaded)
loaded          TRUE if the buffer is loaded.
name            Full path to the file in the buffer.
signs           List of signs placed in the buffer.
                Each list item is a dictionary with
                the following fields:
                    id    sign identifier
                    lnum  line number
                    name  sign name
variables       A reference to the dictionary with
                buffer-local variables.
```

windows List of window-IDs that display this buffer

Examples:

```
for buf in getbufinfo()
    echo buf.name
endfor
for buf in getbufinfo({'buflisted':1})
    if buf.changed
        " ....
    endif
endfor
```

To get buffer-local options use:

```
getbufvar({bufnr}, '&option_name')
```

Parameters:
- {dict} (vim.fn.getbufinfo.dict?)

Return:
(vim.fn.getbufinfo.ret.item[])

getbufline({buf}, {lnum} [, {end}]) getbufline()

Lua: Prefer nvim_buf_get_lines().

Return a List with the lines starting from {lnum} to {end} (inclusive) in the buffer {buf}. If {end} is omitted, a List with only the line {lnum} is returned. See getbufoneline() for only getting the line.

For the use of {buf}, see bufname() above.

For {lnum} and {end} "$" can be used for the last line of the buffer. Otherwise a number must be used.

When {lnum} is smaller than 1 or bigger than the number of lines in the buffer, an empty List is returned.

When {end} is greater than the number of lines in the buffer, it is treated as {end} is set to the number of lines in the buffer. When {end} is before {lnum} an empty List is returned.

This function works only for loaded buffers. For unloaded and non-existing buffers, an empty List is returned.

Example:

```
let lines = getbufline(bufnr("myfile"), 1, "$")
```

Parameters:
- {buf} (integer|string)
- {lnum} (integer)
- {end} (integer?)

Return:
(string[])

getbufoneline({buf}, {lnum}) getbufoneline()

Lua: Prefer nvim_buf_get_lines().

Just like getbufline() but only get one line and return it as a string.

Parameters:
- {buf} (integer|string)
- {lnum} (integer)

Return:
(string)

getbufvar({buf}, {varname} [, {def}]) getbufvar()

Lua: Prefer nvim_buf_get_var() or vim.b after resolving {buf} to a bufnr; option names use nvim_get_option_value() or vim.bo.

Gets the value of a buffer-local variable or option {varname} in buffer {buf}.

{varname} is a string:
- Name of the variable (without "b:").

- If empty, gets a Dictionary of all buffer-local variables.

- If "&", gets a Dictionary of all buffer-local options.

- If it starts with "&", gets the value of a buffer-local

option.

{buf} has the same form as in bufname().

Also works for a global or buffer-local option. But not for a global variable, window-local variable or window-local option.

When the buffer or variable doesn't exist, {def} or an empty string is returned; there is no error.

Examples:

```
let bufmodified = getbufvar(1, "&mod")
echo "todo myvar = " .. getbufvar("todo", "myvar")
```

Parameters:
- {buf} (integer|string)

- {varname} (string)

- {def} (any?)

Return:
(any)

getcellwidths() getcellwidths()

Returns a List of cell widths of character ranges overridden by setcellwidths(). The format is equal to the argument of setcellwidths(). If no character ranges have their cell widths overridden, an empty List is returned.

Return:
(any)

getchangelist([{buf}]) getchangelist()

Returns the changelist for the buffer {buf}. For the use of {buf}, see bufname() above. If buffer {buf} doesn't exist, an empty list is returned.

The returned list contains two entries: a list with the change locations and the current position in the list. Each entry in the change list is a dictionary with the following entries:

col	column number
coladd	column offset for 'virtualedit'
lnum	line number

If buffer {buf} is the current buffer, then the current position refers to the position in the list. For other buffers, it is set to the length of the list.

Parameters:
- {buf} (integer|string?)

Return:
(table[])

getchar([{expr} [, {opts}]]) getchar()

Get a single character from the user or input stream.
If {expr} is omitted or is -1, wait until a character is
available.
If {expr} is 0, only get a character when one is available.
Return zero otherwise.
If {expr} is 1, only check if a character is available, it is
not consumed. Return zero if no character available.
To always get a string, specify "number" as FALSE in {opts}.

Without {expr} and when {expr} is 0 a whole character or special key is returned. If it is a single character, the result is a Number. Use nr2char() to convert it to a String. Otherwise a String is returned with the encoded character. For a special key it's a String with a sequence of bytes starting with 0x80 (decimal: 128). This is the same value as the String "\<Key>", e.g., "\<Left>". The returned value is also a String when a modifier (shift, control, alt) was used that is not included in the character. keytrans() can also be used to convert a returned String into a readable form.

When {expr} is 0 and Esc is typed, there will be a short delay while Vim waits to see if this is the start of an escape

sequence.

When {expr} is 1 only the first byte is returned. For a one-byte character it is the character itself as a number. Use nr2char() to convert it to a String.

Use getcharmod() to obtain any additional modifiers.

The optional argument {opts} is a Dict and supports the following items:

cursor	A String specifying cursor behavior when waiting for a character. "hide": hide the cursor. "keep": keep current cursor unchanged. "msg": move cursor to message area. (default: automagically decide between "keep" and "msg")
number	If TRUE, return a Number when getting a single character. If FALSE, the return value is always converted to a String, and an empty String (instead of 0) is returned when no character is available. (default: TRUE)
simplify	If TRUE, include modifiers in the character if possible. E.g., return the same value for CTRL-I and <Tab>. If FALSE, don't include modifiers in the character. (default: TRUE)

When the user clicks a mouse button, the mouse event will be returned. The position can then be found in v:mouse_col, v:mouse_lnum, v:mouse_winid and v:mouse_win. getmousepos() can also be used. Mouse move events will be ignored.
This example positions the mouse as it would normally happen:

```
let c = getchar()
if c == "\<LeftMouse>" && v:mouse_win > 0
  exe v:mouse_win .. "wincmd w"
  exe v:mouse_lnum
  exe "normal " .. v:mouse_col .. "|"
endif
```

There is no prompt, you will somehow have to make clear to the user that a character has to be typed. The screen is not redrawn, e.g. when resizing the window.

There is no mapping for the character.
Key codes are replaced, thus when the user presses the <Del> key you get the code for the <Del> key, not the raw character sequence. Examples:

```
getchar() == "\<Del>"
getchar() == "\<S-Left>"
```

This example redefines "f" to ignore case:

```
nmap f :call FindChar()<CR>
function FindChar()
  let c = nr2char(getchar())
  while col('.') < col('$') - 1
    normal l
    if getline('.')[col('.') - 1] ==? c
      break
    endif
  endwhile
endfunction
```

Parameters:

- {expr} (-1|0|1?)
- {opts} (table?)

Return:

(integer|string)

getcharmod() getcharmod()

Returns the state of the keyboard modifiers for the last character obtained with getchar() or in another way.
These values are added together:

2	shift
4	control
8	alt (meta)
16	meta (when it's different from ALT)
32	mouse double click
64	mouse triple click

96 mouse quadruple click (== 32 + 64)
128 command (Mac) or super

Only the modifiers that have not been included in the character itself are obtained. Thus Shift-a results in "A" without a modifier. Returns 0 if no modifiers are used.

Return:
(integer)

getcharpos({expr}) getcharpos()

Same as getpos(), except the column-number is character-indexed (UTF-8) instead of byte-indexed.

If getpos() returns v:maxcol, then getcharpos() returns the index of the last character.

Example:
With the cursor on '□' in line 5 with text "□□□□":

```
getcharpos('.')         returns [0, 5, 3, 0]
getpos('.')             returns [0, 5, 7, 0]
```

Parameters:
- {expr} (string)

Return:
(integer[])

getcharsearch() getcharsearch()

Return the current character search information as a {dict} with the following entries:

char	character previously used for a character search (t, f, T, or F); empty string if no character search has been performed
forward	direction of character search; 1 for forward, 0 for backward
until	type of character search; 1 for a t or T character search, 0 for an f or F character search

This can be useful to always have ; and , search forward/backward regardless of the direction of the previous character search:

```
nnoremap <expr> ; getcharsearch().forward ? ';' : ','
nnoremap <expr> , getcharsearch().forward ? ',' : ';'
```

Also see setcharsearch().

Return:
({ char: string, forward: 1|0, until: 1|0 })

getcharstr([{expr} [, {opts}]]) getcharstr()

The same as getchar(), except that this always returns a String, and "number" isn't allowed in {opts}.

Parameters:
- {expr} (-1|0|1?)
- {opts} (table?)

Return:
(string)

getcmdcomplpat() getcmdcomplpat()

Return completion pattern of the current command-line. Only works when the command line is being edited, thus requires use of c_CTRL-_e or c_CTRL-R_=. Also see getcmdtype(), setcmdpos(), getcmdline(), getcmdprompt(), getcmdcompltype() and setcmdline(). Returns an empty string when completion is not defined.

Return:
(string)

getcmdcompltype() getcmdcompltype()

Return the type of the current command-line completion. Only works when the command line is being edited, thus requires use of c_CTRL-_e or c_CTRL-R_=. See :command-completion for the return string. Also see getcmdtype(), setcmdpos(), getcmdline(), getcmdprompt(), getcmdcomplpat() and setcmdline(). Returns an empty string when completion is not defined.

To get the type of the command-line completion for a specified string, use getcompletiontype().

Return:

(string)

getcmdline() getcmdline()

Return the current command-line input. Only works when the command line is being edited, thus requires use of c_CTRL-_e or c_CTRL-R_=.
Example:

```
cmap <F7> <C-\>eescape(getcmdline(), ' \')<CR>
```

Also see getcmdtype(), getcmdpos(), setcmdpos(), getcmdprompt() and setcmdline().
Returns an empty string when entering a password or using inputsecret().

Return:
(string)

getcmdpos() getcmdpos()

Return the position of the cursor in the command line as a byte count. The first column is 1.
Only works when editing the command line, thus requires use of c_CTRL-_e or c_CTRL-R_= or an expression mapping.
Returns 0 otherwise.
Also see getcmdtype(), setcmdpos(), getcmdline(), getcmdprompt() and setcmdline().

Return:
(integer)

getcmdprompt() getcmdprompt()

Return the current command-line prompt when using functions like input() or confirm().
Only works when the command line is being edited, thus requires use of c_CTRL-_e or c_CTRL-R_=.
Also see getcmdtype(), getcmdline(), getcmdpos(), setcmdpos() and setcmdline().

Return:
(string)

getcmdscreenpos() getcmdscreenpos()

Return the screen position of the cursor in the command line as a byte count. The first column is 1.
Instead of getcmdpos(), it adds the prompt position.
Only works when editing the command line, thus requires use of c_CTRL-_e or c_CTRL-R_= or an expression mapping.
Returns 0 otherwise.
Also see getcmdpos(), setcmdpos(), getcmdline() and setcmdline().

Return:
(integer)

getcmdtype() getcmdtype()

Return the current command-line type. Possible return values are:

:	normal Ex command
>	debug mode command debug-mode
/	forward search command
?	backward search command
@	input() command
-	:insert or :append command
=	i_CTRL-R_=

Only works when editing the command line, thus requires use of c_CTRL-_e or c_CTRL-R_= or an expression mapping.
Returns an empty string otherwise.
Also see getcmdpos(), setcmdpos() and getcmdline().

Return:
(':'|'>'|'/'|'?'|'@'|'-'|'='|'')

getcmdwintype() getcmdwintype()

Return the current command-line-window type. Possible return values are the same as getcmdtype(). Returns an empty string when not in the command-line window.

Return:
(':'|'>'|'/'|'?'|'@'|'-'|'='|'')

getcompletion({pat}, {type} [, {filtered}]) getcompletion()

Return a list of command-line completion matches. The String {type} argument specifies what for. The following completion types are supported:

arglist	file names in argument list
augroup	autocmd groups
buffer	buffer names
breakpoint	:breakadd and :breakdel suboptions
cmdline	cmdline-completion result
color	color schemes

```
command         Ex command
compiler        compilers
custom,{func}   custom completion, defined via {func}
customlist,{func} custom completion, defined via {func}
diff_buffer     :diffget and :diffput completion
dir             directory names
dir_in_path     directory names in 'cdpath'
environment     environment variable names
event           autocommand events
expression      Vim expression
file            file and directory names
file_in_path    file and directory names in 'path'
filetype        filetype names 'filetype'
filetypecmd     :filetype suboptions
function        function name
help            help subjects
highlight       highlight groups
history         :history suboptions
keymap          keyboard mappings
locale          locale names (as output of locale -a)
mapclear        buffer argument
mapping         mapping name
menu            menus
messages        :messages suboptions
option          options
packadd         optional package pack-add names
retab           :retab suboptions
runtime         :runtime completion
scriptnames     sourced script names :scriptnames
shellcmd        Shell command
shellcmdline    Shell command line with filename arguments
sign            :sign suboptions
syntax          syntax file names 'syntax'
syntime         :syntime suboptions
tag             tags
tag_listfiles   tags, file names
user            user names
var             user variables
```

If {pat} is an empty string, then all the matches are returned. Otherwise only items matching {pat} are returned. See wildcards for the use of special characters in {pat}.

If the optional {filtered} flag is set to 1, then 'wildignore' is applied to filter the results. Otherwise all the matches are returned. The 'wildignorecase' option always applies.

If the 'wildoptions' option contains "fuzzy", then fuzzy matching is used to get the completion matches. Otherwise regular expression matching is used. Thus this function follows the user preference, what happens on the command line. If you do not want this you can make 'wildoptions' empty before calling getcompletion() and restore it afterwards.

If {type} is "cmdline", then the cmdline-completion result is returned. For example, to complete the possible values after a ":call" command:

```
echo getcompletion('call ', 'cmdline')
```

If there are no matches, an empty list is returned. An invalid value for {type} produces an error.

Parameters:

- {pat} (string)
- {type} (string)
- {filtered} (boolean?)

Return:

(string[])

getcompletiontype({pat}) getcompletiontype()

Return the type of the command-line completion using {pat}. When no corresponding completion type is found, an empty string is returned.
To get the current command-line completion type, use getcmdcompltype().

Parameters:

- {pat} (string)

Return:

(string)

getcurpos([{winid}]) getcurpos()

Lua: Prefer nvim_win_get_cursor(); return shape, 0-based column, and curswant/invalid-window semantics differ.

Get the position of the cursor. This is like getpos('.'), but includes an extra "curswant" item in the list:

[0, lnum, col, off, curswant]

The "curswant" number is the preferred column when moving the cursor vertically. After $ command it will be a very large number equal to v:maxcol. Also see getcursorcharpos() and getpos().
The first "bufnum" item is always zero. The byte position of the cursor is returned in "col". To get the character position, use getcursorcharpos().

The optional {winid} (window-number or window-ID) specifies the window. The last known cursor position is returned, this may be invalid for the current value of the buffer if it is not the current window.
If {winid} is invalid a list with zeroes is returned.

This can be used to save and restore the cursor position:

```
let save_cursor = getcurpos()
MoveTheCursorAround
call setpos('.', save_cursor)
```

Note that this only works within the window. See winrestview() for restoring more state.

Parameters:
- {winid} (integer?)

Return:
([integer, integer, integer, integer, integer])

getcursorcharpos([{winid}]) getcursorcharpos()

Same as getcurpos() but the column number in the returned List is a character index instead of a byte index.

Example:
With the cursor on '□' in line 3 with text "□□□□":

```
getcursorcharpos()      " returns [0, 3, 2, 0, 3]
getcurpos()             " returns [0, 3, 4, 0, 3]
```

Parameters:
- {winid} (integer?)

Return:
(any)

getcwd([{winnr} [, {tabnr} [, {bufnr}]]]) getcwd() E5000 E5002 E5006 E5007

Without arguments, returns the effective current-directory.
With {winnr} (window-number or window-ID), {tabnr} or {bufnr} the working directory of that scope is returned, ignoring 'autochdir'.

- If {winnr} is -1: gets the tabpage directory.
- If {winnr} and {tabnr} are both -1: gets the global directory.
  - **Note:** Vim returns an empty string when {tabnr} is -1.
- If {bufnr} is given: gets the buffer-local directory.
- An argument may be -1 only if preceding args are -1. E5001 ({winnr} and {tabnr} must be -1.)

Tabs, windows and buffers are identified by their respective numbers, 0 means current tab/window/buffer. Missing {tabnr} implies 0 (missing {bufnr} does not; see below). Thus the following are equivalent:

```
getcwd(0)
getcwd(0, 0)
```

Each form reports its own scope or "wider", so e.g. {winnr} never reports a buffer-local directory. The {bufnr} form falls back to the global directory, because a buffer belongs to no particular window or tabpage.

Examples:

```
getcwd(-1, -1, 0)  " Get current buffer's directory
getcwd(-1, -1, 3)  " Get directory of buffer 3
getcwd(-1, -1, -1) " Get global directory
getcwd(-1, -1)     " Get global directory
```

Parameters:
- {winnr} (integer?)

- {tabnr} (integer?)

- {bufnr} (integer?)

Return:
(string)

getenv({name}) getenv()

Lua: Prefer vim.env.

Return the value of environment variable {name}. The {name} argument is a string, without a leading '$'. Example:

```
myHome = getenv('HOME')
```

When the variable does not exist v:null is returned. That is different from a variable set to an empty string.
See also expr-env.

Parameters:
- {name} (string)

Return:
(string)

getfontname([{name}]) getfontname()

Without an argument returns the name of the normal font being used. Like what is used for the Normal highlight group hl-Normal.
With an argument a check is done whether String {name} is a valid font name. If not then an empty string is returned.
Otherwise the actual font name is returned, or {name} if the GUI does not support obtaining the real name.
Only works when the GUI is running, thus not in your vimrc or gvimrc file. Use the GUIEnter autocommand to use this function just after the GUI has started.

Parameters:
- {name} (string?)

Return:
(string)

getfperm({fname}) getfperm()

Lua: Prefer uv.fs_stat().

Returns the file permissions of the given file {fname} as a String. If {fname} does not exist or its directory cannot be read, an empty string is returned.
The result is of the form "rwxrwxrwx", where each group of "rwx" flags represent, in turn, the permissions of the owner of the file, the group the file belongs to, and other users.
If a user does not have a given permission the flag for this is replaced with the string "-". Examples:

```
echo getfperm("/etc/passwd")
echo getfperm(expand("~/.config/nvim/init.vim"))
```

This will hopefully (from a security point of view) display the string "rw-r--r--" or even "rw-------".

For setting permissions use setfperm().

Attributes:
api-fast

Parameters:
- {fname} (string)

Return:
(string)

getfsize({fname}) getfsize()

Lua: Prefer uv.fs_stat().

Returns the size in bytes of the given file {fname}.
If {fname} is a directory, 0 is returned.

If the file {fname} can't be found, -1 is returned.
If the size of {fname} is too big to fit in a Number then -2
is returned.

Attributes:
api-fast

Parameters:
- {fname} (string)

Return:
(integer)

getftime({fname}) getftime()

Lua: Prefer uv.fs_stat().

Returns the last modification time ("mtime") of file {fname}.
The value is measured as seconds since 1st Jan 1970, and may
be passed to strftime(). See also
localtime() and strftime().
If the file {fname} can't be found -1 is returned.

Attributes:
api-fast

Parameters:
- {fname} (string)

Return:
(integer)

getftype({fname}) getftype()

Lua: Prefer uv.fs_stat().

Returns a description of the type of file {fname} as a
String. If {fname} does not exist an empty string is
returned.
Here is a table over different kinds of files and their
results:

Normal file	"file"
Directory	"dir"
Symbolic link	"link"
Block device	"bdev"
Character device	"cdev"
Socket	"socket"
FIFO	"fifo"
All other	"other"

Example:

```
getftype("/home")
```

Note that a type such as "link" will only be returned on
systems that support it. On some systems only "dir" and
"file" are returned.

Attributes:
api-fast

Parameters:
- {fname} (string)

Return:
('file'|'dir'|'link'|'bdev'|'cdev'|'socket'|'fifo'|'other')

getjumplist([{winnr} [, {tabnr}]]) getjumplist()

Lua: Prefer nvim_get_context() for current jump history;
window/tab arguments and return shape differ.

Returns the jumplist for the specified window.

Without arguments use the current window.
With {winnr} (window-number or window-ID) only use this
window in the current tabpage.
With {winnr} and {tabnr} use the window in the specified tab
page. If {winnr} or {tabnr} is invalid, an empty list is
returned.

The returned list contains two entries: a list with the jump
locations and the last used jump position number in the list.
Each entry in the jump location list is a dictionary with
the following entries:

bufnr	buffer number
col	column number
coladd	column offset for 'virtualedit'
filename	filename if available
lnum	line number

Parameters:
- {winnr} (integer?)

- {tabnr} (integer?)

Return:
(vim.fn.getjumplist.ret)

getline({lnum}) getline()

Lua: Prefer nvim_get_current_line() or nvim_buf_get_lines().

Without {end} the result is a String, which is line {lnum} from the current buffer. Example:

```
getline(1)
```

When {lnum} is a String that doesn't start with a digit, line() is called to translate the String into a Number. To get the line under the cursor:

```
getline(".")
```

When {lnum} is a number smaller than 1 or bigger than the number of lines in the buffer, an empty string is returned.

Parameters:
- {lnum} (integer|string)

Return:
(string)

getline({lnum}, {end})
Lua: Prefer nvim_buf_get_lines().

When {end} is given the result is a List where each item is a line from the current buffer in the range {lnum} to {end}, including line {end}.
{end} is used in the same way as {lnum}.
Non-existing lines are silently omitted.
When {end} is before {lnum} an empty List is returned.
Example:

```
let start = line('.')
let end = search("^$") - 1
let lines = getline(start, end)
```

To get lines from another buffer see getbufline() and getbufoneline()

Parameters:
- {lnum} (integer|string)

- {end} (integer|string)

Return:
(string[])

getloclist({nr}) getloclist()

Returns a List with all the entries in the location list for window {nr} (window-number or window-ID). When {nr} is zero the current window is used.

For a location list window, the displayed location list is returned. For an invalid {nr}, an empty list is returned. Otherwise, same as getqflist().

Parameters:
- {nr} (integer)

Return:
(vim.fn.getqflist.ret.item[])

getloclist({nr}, {what})
If the optional {what} dictionary argument is supplied, then returns the items listed in {what} as a dictionary. Refer to getqflist() for the supported items in {what}.

In addition to the items supported by getqflist() in {what}, the following item is supported by getloclist():

filewinid id of the window used to display files from the location list. This field is applicable only when called from a location list window. See location-list-file-window for more details.

Returns a Dictionary with default values if there is no location list for the window {nr}.
Returns an empty Dictionary if window {nr} does not exist.

Examples (See also getqflist-examples):

```
echo getloclist(3, {'all': 0})
echo getloclist(5, {'filewinid': 0})
```

Parameters:
- {nr} (integer)

- {what} (vim.fn.getloclist.what)

Return:
(vim.fn.getloclist.ret)

getmarklist([{buf}]) getmarklist()

Without the {buf} argument returns a List with information about all the global marks. mark

If the optional {buf} argument is specified, returns the local marks defined in buffer {buf}. For the use of {buf}, see bufname(). If {buf} is invalid, an empty list is returned. For a prompt-buffer the result includes the ': mark.

Each item in the returned List is a Dict with the following:
```
    mark   name of the mark prefixed by "'"
    pos    a List with the position of the mark:
               [bufnum, lnum, col, off]
           Refer to getpos() for more information.
    file   file name
```

Refer to getpos() for getting information about a specific mark.

Parameters:
- {buf} (integer??)

Return:
(vim.fn.getmarklist.ret.item[])

getmatches([{win}]) getmatches()

Returns a List with all matches previously defined for the current window by matchadd() and the :match commands. getmatches() is useful in combination with setmatches(), as setmatches() can restore a list of matches saved by getmatches().
If {win} is specified, use this window-number or window-ID instead of the current window. If {win} is invalid, an empty list is returned.
Example:

```
echo getmatches()
```

```
[{"group": "MyGroup1", "pattern": "TODO",
"priority": 10, "id": 1}, {"group": "MyGroup2",
"pattern": "FIXME", "priority": 10, "id": 2}]
```

```
let m = getmatches()
call clearmatches()
echo getmatches()
```

```
[]
```

```
call setmatches(m)
echo getmatches()
```

```
[{"group": "MyGroup1", "pattern": "TODO",
"priority": 10, "id": 1}, {"group": "MyGroup2",
"pattern": "FIXME", "priority": 10, "id": 2}]
```

```
unlet m
```

Parameters:
- {win} (integer?)

Return:
(vim.fn.getmatches.ret.item[])

getmousepos() getmousepos()

Returns a Dictionary with the last known position of the mouse. This can be used in a mapping for a mouse click. The items are:
```
        screenrow       screen row
        screencol       screen column
        winid           Window ID of the click
```

winrow row inside "winid"
wincol column inside "winid"
line text line inside "winid"
column text column inside "winid"
coladd offset (in screen columns) from the start of the clicked char

All numbers are 1-based.

If not over a window, e.g. when in the command line, then only "screenrow" and "screencol" are valid, the others are zero.

When on the status line below a window or the vertical separator right of a window, the "line" and "column" values are zero.

When the position is after the text then "column" is the length of the text in bytes plus one.

If the mouse is over a focusable floating window then that window is used.

When using getchar() the Vim variables v:mouse_lnum, v:mouse_col and v:mouse_winid also provide these values.

Return:

(vim.fn.getmousepos.ret)

getpid() getpid()

Lua: Prefer uv.os_getpid().

Return a Number which is the process ID of the Vim process. This is a unique number, until Vim exits.

Attributes:

api-fast

Return:

(integer)

getpos({expr}) getpos()

Lua: Prefer nvim_win_get_cursor() for "." or nvim_buf_get_mark() for marks; return shape, off, and special-position semantics differ.

Gets a position, where {expr} is one of:

. Cursor position.
$ Last line in the current buffer.
'x Position of mark x (if the mark is not set, 0 is returned for all values).
w0 First line visible in current window (one if the display isn't updated, e.g. in silent-mode).
w$ Last line visible in current window (this is one less than "w0" if no lines are visible).
v End of the current Visual selection (unlike '< '> which give the previous, not current, Visual selection), or the cursor position if not in Visual mode.

To get the current selected region:

```
let region = getregionpos(getpos('v'), getpos('.'))
```

Explanation: in Visual mode "v" and "." complement each other. While "." refers to the cursor position, "v" refers to where v_o would move the cursor. So you can use "v" and "." together to get the selected region.

Note that if a mark in another file is used, the line number applies to that buffer.

The result is a List with four numbers:
[bufnum, lnum, col, off]
"bufnum" is zero, unless a mark like '0 or 'A is used, then it is the buffer number of the mark.
"lnum" and "col" are the position in the buffer. The first column is 1.
The "off" number is zero, unless 'virtualedit' is used. Then it is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character.

For getting the cursor position see getcurpos().
The column number in the returned List is the byte position within the line. To get the character position in the line, use getcharpos().

The visual marks '< and '> refer to the beginning and end of the visual selection relative to the buffer. Note that this differs from setpos(), where they are relative to the cursor position.

Note that for '< and '> Visual mode matters: when it is "V" (visual line mode) the column of '< is zero and the column of '> is a large number equal to v:maxcol.
A very large column number equal to v:maxcol can be returned, in which case it means "after the end of the line".
If {expr} is invalid, returns a list with all zeros.

This can be used to save and restore the position of a mark:

```
let save_a_mark = getpos("'a")
" ...
call setpos("'a", save_a_mark)
```

Also see getcharpos(), getcurpos() and setpos().

Parameters:

- {expr} (string)

Return:

([integer, integer, integer, integer])

getqflist() getqflist()

Returns a List with all the current quickfix errors. Each list item is a dictionary with these entries:

```
bufnr   number of buffer that has the file name, use
        bufname() to get the name
module  module name
lnum    line number in the buffer (first line is 1)
end_lnum
        end of line number if the item is multiline
col     column number (first column is 1)
end_col end of column number if the item has range
vcol    TRUE: "col" is visual column
        FALSE: "col" is byte index
nr      error number
pattern search pattern used to locate the error
text    description of the error
type    type of the error, 'E', '1', etc.
valid   TRUE: recognized error message
user_data
        any type.  This entry is present only when
        user data was set for this item.
```

When there is no error list or it's empty, an empty list is returned. Quickfix list entries with a non-existing buffer number are returned with "bufnr" set to zero (**Note:** some functions accept buffer number zero for the alternate buffer, you may need to explicitly check for zero).

Useful application: Find pattern matches in multiple files and do something with them:

```
vimgrep /theword/jg *.c
for d in getqflist()
   echo bufname(d.bufnr) ':' d.lnum '=' d.text
endfor
```

Return:

(vim.fn.getqflist.ret.item[])

getqflist({what})

If the optional {what} dictionary argument is supplied, then returns only the items listed in {what} as a dictionary. The following string items are supported in {what}:

```
changedtick     get the total number of changes made
                to the list quickfix-changedtick
context get the quickfix-context
efm     errorformat to use when parsing "lines".  If
        not present, then the 'errorformat' option
        value is used.
id      get information for the quickfix list with
        quickfix-ID; zero means the id for the
        current list or the list specified by "nr"
idx     get information for the quickfix entry at this
        index in the list specified by "id" or "nr".
        If set to zero, then uses the current entry.
        See quickfix-index
items   quickfix list entries
lines   parse a list of lines using 'efm' and return
        the resulting entries.  Only a List type is
        accepted.  The current quickfix list is not
        modified.  See quickfix-parse.
nr      get information for this quickfix list; zero
        means the current quickfix list and "$" means
        the last quickfix list
qfbufnr number of the buffer displayed in the quickfix
        window.  Returns 0 if the quickfix buffer is
        not present.  See quickfix-buffer.
quickfixtextfunc
        function to get the text to display in the
        quickfix window.  Returns an empty string if
        this function is not set for the list.  See
        quickfix-window-function.
size    number of entries in the quickfix list
title   get the list title quickfix-title
winid   get the quickfix window-ID
all     all of the above quickfix properties
```

Non-string items in {what} are ignored. To get the value of a particular item, set it to zero.

If "nr" is not present then the current quickfix list is used.
If both "nr" and a non-zero "id" are specified, then the list
specified by "id" is used.
To get the number of lists in the quickfix stack, set "nr" to
"$" in {what}. The "nr" value in the returned dictionary
contains the quickfix stack size.
When "lines" is specified, all the other items except "efm"
are ignored. The returned dictionary contains the entry
"items" with the list of entries.

The returned dictionary contains the following entries:

changedtick	total number of changes made to the list quickfix-changedtick
context	quickfix list context. See quickfix-context If not present, set to "".
id	quickfix list ID quickfix-ID. If not present, set to 0.
idx	index of the quickfix entry in the list. If not present, set to 0.
items	quickfix list entries. If not present, set to an empty list.
nr	quickfix list number. If not present, set to 0
qfbufnr	number of the buffer displayed in the quickfix window. If not present, set to 0.
quickfixtextfunc	'quickfixtextfunc' setting of the list. If not present, set to "".
size	number of entries in the quickfix list. If not present, set to 0.
title	quickfix list title text. If not present, set to "".
winid	quickfix window-ID. If not present, set to 0

Examples (See also getqflist-examples):

```
echo getqflist({'all': 1})
echo getqflist({'nr': 2, 'title': 1})
echo getqflist({'lines' : ["F1:10:L10"]})
```

Parameters:
- {what} (vim.fn.getqflist.what)

Return:
(vim.fn.getqflist.ret)

getreg([{regname} [, 1 [, {list}]]]) getreg()

Returns the contents of register {regname} as a String.
Example:

```
let cliptext = getreg('*')
```

When register {regname} was not set the result is an empty
string.
The {regname} argument must be a string.

getreg('=') returns the last evaluated value of the expression
register. (For use in maps.)
getreg('=', 1) returns the expression itself, so that it can
be restored with setreg(). For other registers the extra
argument is ignored, thus you can always give it.

If {list} is present and TRUE, the result type is changed
to List. Each list item is one text line. Use it if you care
about zero bytes possibly present inside register: without
third argument both NLs and zero bytes are represented as NLs
(see NL-used-for-Nul).
When the register was not set an empty list is returned.

If {regname} is not specified, v:register is used.

Parameters:
- {regname} (string?)
- {expr} (any?)
- {list} (nil|false?)

Return:
(string)

getreginfo([{regname}]) getreginfo()

Returns detailed information about register {regname} as a
Dictionary with the following entries:

regcontents	List of lines contained in register {regname}, like getreg({regname}, 1, 1).

regtype the type of register {regname}, as in getregtype().
isunnamed Boolean flag, v:true if this register is currently pointed to by the unnamed register.
points_to for the unnamed register, gives the single letter name of the register currently pointed to (see quotequote). For example, after deleting a line with dd, this field will be "1", which is the register that got the deleted text.

The {regname} argument is a string. If {regname} is invalid or not set, an empty Dictionary will be returned.
If {regname} is not specified, v:register is used.
The returned Dictionary can be passed to setreg().

Parameters:
- {regname} (string?)

Return:
(table)

getregion({pos1}, {pos2} [, {opts}]) getregion()

Returns the list of strings from {pos1} to {pos2} from a buffer.

{pos1} and {pos2} must both be Lists with four numbers. See getpos() for the format of the list. It's possible to specify positions from a different buffer, but please note the limitations at getregion-notes.

The optional argument {opts} is a Dict and supports the following items:

type Specify the region's selection type. See getregtype() for possible values, except that the width can be omitted and an empty string cannot be used. (default: "v")

exclusive If TRUE, use exclusive selection for the end position. (default: follow 'selection')

You can get the last selection type by visualmode().
If Visual mode is active, use mode() to get the Visual mode (e.g., in a :vmap).
This function is useful to get text starting and ending in different columns, such as a charwise-visual selection.

getregion-notes

Note that:
- Order of {pos1} and {pos2} doesn't matter, it will always return content from the upper left position to the lower right position.
- If 'virtualedit' is enabled and the region is past the end of the lines, resulting lines are padded with spaces.
- If the region is blockwise and it starts or ends in the middle of a multi-cell character, it is not included but its selected part is substituted with spaces.
- If {pos1} and {pos2} are not in the same buffer, an empty list is returned.
- {pos1} and {pos2} must belong to a bufloaded() buffer.
- It is evaluated in current window context, which makes a difference if the buffer is displayed in a window with different 'virtualedit' or 'list' values.
- When specifying an exclusive selection and {pos1} and {pos2} are equal, the returned list contains a single character as if selection is inclusive, to match the behavior of an empty exclusive selection in Visual mode.

Examples:

```
xnoremap <CR>
\ <Cmd>echom getregion(
\ getpos('v'), getpos('.'), #{ type: mode() })<CR>
```

Parameters:

- {pos1} ([integer, integer, integer, integer])
- {pos2} ([integer, integer, integer, integer])
- {opts} ({type?:string, exclusive?:boolean}?)

Return:

(string[])

getregionpos({pos1}, {pos2} [, {opts}]) getregionpos()

Same as getregion(), but returns a list of positions describing the buffer text segments bound by {pos1} and {pos2}.
The segments are a pair of positions for every line:

```
[[{startpos}, {endpos}], ...]
```

The position is a List with four numbers:
    [bufnum, lnum, col, off]
"bufnum" is the buffer number.
"lnum" and "col" are the position in the buffer. The first column is 1.
If the "off" number of a starting position is non-zero, it is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character.
If the "off" number of an ending position is non-zero, it is the offset of the character's first cell not included in the selection, otherwise all its cells are included.

To get the current visual selection:

```
let region = getregionpos(getpos('v'), getpos('.'))
```

The {opts} Dict supports the following items:

type	See getregion().
exclusive	See getregion().
eol	If TRUE, indicate positions beyond the end of a line with "col" values one more than the length of the line. If FALSE, positions are limited within their lines, and if a line is empty or the selection is entirely beyond the end of a line, a "col" value of 0 is used for both positions. (default: FALSE)
bounds	If TRUE, return only the outer bounds of the region as a single pair:

```
[[{startpos}, {endpos}]]
```

{startpos} is the start position on the first line of the region and {endpos} the end position on its last line. The lines in between are not visited, which is much faster for a large region.
(default: FALSE)

Using "bounds" with the same {opts} is equivalent to taking the outer positions of the full result:

```
let full = getregionpos(pos1, pos2, opts)
let bounds = [[full[0][0], full[-1][1]]]
```

When the full result is empty, e.g. because {pos1} and {pos2} are in different buffers, the result is empty as well.
Note that the two positions then come from different lines, so they describe a diagonal of the region and not its shape. For a blockwise region they are the start of the first line and the end of the last line, not the corners of the block.
Likewise, when the first line is empty and "eol" is FALSE, {startpos} has a "col" of 0 while {endpos} may not.

Parameters:

- {pos1} ([integer, integer, integer, integer])
- {pos2} ([integer, integer, integer, integer])
- {opts}

({type?:string, exclusive?:boolean, eol?:boolean, bounds?:boolean}?)

Return:

([[integer, integer, integer, integer], [integer, integer, integer, integer]][])

getregtype([{regname}]) getregtype()

Returns the type of register {regname} as a String.
The value will be one of:

"v"	for charwise text
"V"	for linewise text
"<CTRL-V>{width}"	for blockwise-visual text
""	for an empty or unknown register

<CTRL-V> is one character with value 0x16.
The {regname} argument is a string. If {regname} is not specified, v:register is used.

Parameters:

- {regname} (string?)

Return:

(string)

getscriptinfo([{opts}]) getscriptinfo()

Returns a List with information about all the sourced Vim scripts in the order they were sourced, like what :scriptnames shows.

The optional Dict argument {opts} supports the following optional items:

name	Script name match pattern. If specified, and "sid" is not specified, information about scripts with a name that match the pattern "name" are returned.
sid	Script ID <SID>. If specified, only information about the script with ID "sid" is returned and "name" is ignored.

Each item in the returned List is a Dict with the following items:

autoload	Always set to FALSE.
functions	List of script-local function names defined in the script. Present only when a particular script is specified using the "sid" item in {opts}.
name	Vim script file name.
sid	Script ID <SID>.
variables	A dictionary with the script-local variables. Present only when a particular script is specified using the "sid" item in {opts}. Note that this is a copy, the value of script-local variables cannot be changed using this dictionary.
version	Vim script version, always 1

Examples:

```
echo getscriptinfo({'name': 'myscript'})
echo getscriptinfo({'sid': 15})[0].variables
```

Parameters:

- {opts} (table?)

Return:

(vim.fn.getscriptinfo.ret[])

getstacktrace() getstacktrace()

Lua: Prefer debug.traceback().

Returns the current stack trace of Vim scripts.
Stack trace is a List, of which each item is a Dictionary with the following items:

funcref	The funcref if the stack is at a function, otherwise this item is omitted.
event	The string of the event description if the stack is at an autocmd event, otherwise this item is omitted.
lnum	The line number in the script on the stack.
filepath	The file path of the script on the stack.

Return:

(table[])

gettabinfo([{tabnr}]) gettabinfo()

If {tabnr} is not specified, then information about all the tabpages is returned as a List. Each List item is a Dictionary. Otherwise, {tabnr} specifies the tabpage number and information about that one is returned. If the tab page does not exist an empty List is returned.

Each List item is a Dictionary with the following entries:

tabnr	tabpage-number

variables a reference to the dictionary with tabpage-local variables
windows List of window-IDs in the tabpage.

Parameters:
- {tabnr} (integer?)

Return:
(any)

gettabvar({tabnr}, {varname} [, {def}]) gettabvar()

Lua: Prefer nvim_tabpage_get_var() or vim.t.

Get the value of a tab-local variable {varname} in tabpage {tabnr}. t:var
Tabs are numbered starting with one.
The {varname} argument is a string. When {varname} is empty a dictionary with all tab-local variables is returned.
Note that the name without "t:" must be used.
When the tab or variable doesn't exist {def} or an empty string is returned, there is no error message.

Parameters:
- {tabnr} (integer)
- {varname} (string)
- {def} (any?)

Return:
(any)

gettabwinvar({tabnr}, {winnr}, {varname} [, {def}]) gettabwinvar()

Lua: Prefer nvim_win_get_var() or vim.w after resolving {tabnr} and {winnr} to a winid; option names use nvim_get_option_value() or vim.wo.

Gets the value of window-local variable {varname} in {winnr} (window-number or window-ID) in tabpage-number {tabnr}.

{varname} is a string:
- Name of the variable (without "w:").
- If empty, gets a dictionary with all window-local variables.
- If "&", gets the values of all window-local options in a Dictionary.
- If it starts with "&", gets the value of a window-local option.

To get window-local variables in the current tabpage use getwinvar().

When {winnr} is zero the current window is used.

Also works for a global option, buffer-local option, window-local option, and tab-local option ('cmdheight'). But not for a global variable or buffer-local variable.

When the tab, window or variable doesn't exist, {def} or an empty string is returned; there is no error.

Examples:

```
let list_is_on = gettabwinvar(1, 2, '&list')
echo "myvar = " .. gettabwinvar(3, 1, 'myvar')
```

To get all window-local variables:

```
gettabwinvar({tabnr}, {winnr}, '&')
```

Parameters:
- {tabnr} (integer)
- {winnr} (integer)
- {varname} (string)
- {def} (any?)

Return:

(any)

gettagstack([{winnr}]) gettagstack()

Returns the tag stack of window {winnr} (window-number or window-ID) as a Dict.
When {winnr} is not specified, the current window is used.
When window {winnr} doesn't exist, an empty Dict is returned.

The returned dictionary contains the following entries:

curidx	Current index in the stack. When at top of the stack, set to (length + 1). Index of bottom of the stack is 1.
items	List of items in the stack. Each item is a dictionary containing the entries described below.
length	Number of entries in the stack.

Each item in the stack is a dictionary with the following entries:

bufnr	buffer number of the current jump
from	cursor position before the tag jump. See getpos() for the format of the returned list.
matchnr	current matching tag number. Used when multiple matching tags are found for a name.
tagname	name of the tag

See tagstack for more information about the tag stack.

Parameters:

- {winnr} (integer?)

Return:

(any)

gettext({text}) gettext()

Translate String {text} if possible.
This is mainly for use in the distributed Vim scripts. When generating message translations the {text} is extracted by xgettext, the translator can add the translated message in the .po file and Vim will lookup the translation when gettext() is called.
For {text} double quoted strings are preferred, because xgettext does not understand escaping in single quoted strings.

Parameters:

- {text} (string)

Return:

(string)

getwininfo([{winid}]) getwininfo()

Returns information about windows as a List with Dictionaries.

If {winid} is given Information about the window with that ID is returned, as a List with one item. If the window does not exist the result is an empty list.

Without {winid} information about all the windows in all the tabpages is returned.

Each List item is a Dictionary with the following entries:

botline	last complete displayed buffer line
bufnr	number of buffer in the window
height	window height (excluding winbar)
leftcol	first column displayed; only used when 'wrap' is off
loclist	1 if showing a location list
quickfix	1 if quickfix or location list window
status_height	status lines height (0 or 1)
tabnr	tabpage-number
terminal	1 if a terminal window
textoff	number of columns occupied by any 'foldcolumn', 'signcolumn' and line number in front of the text
topline	first displayed buffer line
variables	a reference to the dictionary with window-local variables
width	window width
winbar	1 if the window has a toolbar, 0 otherwise
wincol	leftmost screen column of the window; "col" from win_screenpos()
winid	window-ID
winnr	window-number
winrow	topmost screen line of the window; "row" from win_screenpos()

Parameters:
- {winid} (integer?)

Return:
(vim.fn.getwininfo.ret.item[])

getwinpos([{timeout}]) getwinpos()

Returns the [x, y] screen position of the Nvim GUI window as a List with two numbers (result of getwinposx() and getwinposy() combined).

{timeout} can be used to specify how long to wait in msec for a response. When omitted 100 msec is used.

Use a longer time for a remote terminal.
When using a value less than 10 and no response is received within that time, a previously reported position is returned, if available. This can be used to poll for the position and do some work in the meantime:

```
while 1
  let res = getwinpos(1)
  if res[0] >= 0
    break
  endif
  " Do some work here
endwhile
```

Parameters:
- {timeout} (integer?)

Return:
(any)

getwinposx() getwinposx()

Returns the X coordinate in pixels of the left hand side of the Nvim GUI window, or -1 if not available. The value can be used with :winpos.

Return:
(integer)

getwinposy() getwinposy()

Returns the Y coordinate in pixels of the top of the Nvim GUI window, or -1 if not available. The value can be used with :winpos.

Return:
(integer)

getwinvar({winnr}, {varname} [, {def}]) getwinvar()

Lua: Prefer nvim_win_get_var() or vim.w after resolving {winnr}; option names use nvim_get_option_value() or vim.wo.

Like gettabwinvar() for the current tabpage.
Examples:

```
let list_is_on = getwinvar(2, '&list')
echo "myvar = " .. getwinvar(1, 'myvar')
```

Parameters:
- {winnr} (integer)
- {varname} (string)
- {def} (any?)

Return:
(any)

glob({expr} [, {nosuf} [, {list} [, {alllinks}]]]) glob()

Expand the file wildcards in {expr}. See wildcards for the use of special characters.

Unless the optional {nosuf} argument is given and is TRUE, the 'suffixes' and 'wildignore' options apply: Names matching one of the patterns in 'wildignore' will be skipped and 'suffixes' affect the ordering of matches.
'wildignorecase' always applies.

When {list} is present and it is TRUE the result is a List with all matching files. The advantage of using a List is, you also get filenames containing newlines correctly.

Otherwise the result is a String and when there are several
matches, they are separated by <NL> characters.

If the expansion fails, the result is an empty String or List.

You can also use readdir() if you need to do complicated
things, such as limiting the number of matches.

A name for a non-existing file is not included. A symbolic
link is only included if it points to an existing file.
However, when the {alllinks} argument is present and it is
TRUE then all symbolic links are included.

For most systems backticks can be used to get files names from
any external command. Example:

```
let tagfiles = glob("`find . -name tags -print`")
let &tags = substitute(tagfiles, "\n", ",", "g")
```

The result of the program inside the backticks should be one
item per line. Spaces inside an item are allowed.

See expand() for expanding special Vim variables. See
system() for getting the raw output of an external command.

Parameters:

- {expr} (string)
- {nosuf} (boolean?)
- {list} (boolean?)
- {alllinks} (boolean?)

Return:

(any)

glob2regpat({string}) glob2regpat()

Convert a file pattern, as used by glob(), into a search
pattern. The result can be used to match with a string that
is a file name. E.g.

```
if filename =~ glob2regpat('Make*.mak')
  " ...
endif
```

This is equivalent to:

```
if filename =~ '^Make.*\.mak$'
  " ...
endif
```

When {string} is an empty string the result is "^$", match an
empty string.
Note that the result depends on the system. On MS-Windows
a backslash usually means a path separator.

Parameters:

- {string} (string)

Return:

(string)

globpath({path}, {expr} [, {nosuf} [, {list} [, {alllinks}]]]) globpath()

Perform glob() for String {expr} on all directories in {path}
and concatenate the results. Example:

```
echo globpath(&rtp, "syntax/c.vim")
```

{path} is a comma-separated list of directory names. Each
directory name is prepended to {expr} and expanded like with
glob(). A path separator is inserted when needed.
To add a comma inside a directory name escape it with a
backslash. Note that on MS-Windows a directory may have a
trailing backslash, remove it if you put a comma after it.
If the expansion fails for one of the directories, there is no
error message.

Unless the optional {nosuf} argument is given and is TRUE,
the 'suffixes' and 'wildignore' options apply: Names matching
one of the patterns in 'wildignore' will be skipped and
'suffixes' affect the ordering of matches.

When {list} is present and it is TRUE the result is a List
with all matching files. The advantage of using a List is,
you also get filenames containing newlines correctly.
Otherwise the result is a String and when there are several
matches, they are separated by <NL> characters. Example:

```
echo globpath(&rtp, "syntax/c.vim", 0, 1)
```

{allinks} is used as with glob().

The "**" item can be used to search in a directory tree.
For example, to find all "README.txt" files in the directories
in 'runtimepath' and below:

```
echo globpath(&rtp, "**/README.txt")
```

Upwards search and limiting the depth of "**" is not
supported, thus using 'path' will not always work properly.

Parameters:

- {path} (string)
- {expr} (string)
- {nosuf} (boolean?)
- {list} (boolean?)
- {allinks} (boolean?)

Return:

(any)

has({feature}) has()

Returns 1 if {feature} is supported, 0 otherwise. The
{feature} argument is a feature name like "nvim-0.2.1" or
"win32", see below. See also exists().

To get the system name use vim.uv.os_uname() in Lua:

```
print(vim.uv.os_uname().sysname)
```

If the code has a syntax error then Vimscript may skip the
rest of the line. Put :if and :endif on separate lines to
avoid the syntax error:

```
if has('feature')
  let x = this_breaks_without_the_feature()
endif
```

Vim's compile-time feature-names (prefixed with "+") are not
recognized because Nvim is always compiled with all possible
features. feature-compile

Feature names can be:

1. Nvim version. For example the "nvim-0.2.1" feature means

   that Nvim is version 0.2.1 or later:

   ```
   if has("nvim-0.2.1")
     " ...
   endif
   ```

2. Runtime condition or other pseudo-feature. For example the

   "win32" feature checks if the current system is Windows:

   ```
   if has("win32")
     " ...
   endif
   ```

feature-list

List of supported pseudo-feature names:

acl	ACL support.
android	Android system (not necessarily termux).
bsd	BSD system (not macOS, use "mac" for that).
clipboard	clipboard provider is available.
fname_case	Case in file names matters (for Darwin and MS-Windows this is not present).
gui_running	Nvim has a GUI.
hurd	GNU/Hurd system.
iconv	Can use iconv() for conversion.
linux	Linux system.
mac	MacOS system.
nvim	This is Nvim.
python3	Legacy Vim python3 interface. has-python
pythonx	Legacy Vim python_x interface. has-pythonx

sun	SunOS system.
termux	Termux, an android terminal app and packaging environment.
ttyin	input is a terminal (tty).
ttyout	output is a terminal (tty).
unix	Unix system.
vim_starting	True during startup.
win32	Windows system (32 or 64 bit).
win64	Windows system (64 bit).
wsl	WSL (Windows Subsystem for Linux) system.

has-patch

1. Vim patch. For example the "patch123" feature means that

   Vim patch 123 at the current v:version was included:

```
if v:version > 602 || v:version == 602 && has("patch148")
  " ...
endif
```

2. Vim version. For example the "patch-7.4.237" feature means

   that Nvim is Vim-compatible to version 7.4.237 or later.

```
if has("patch-7.4.237")
  " ...
endif
```

Attributes:
api-fast

Parameters:
- {feature} (string)

Return:
(0|1)

has_key({dict}, {key}) has_key()

Lua: Prefer dict[key] ~= nil.

Checks whether Dictionary {dict} has an entry with key {key}. Returns TRUE if so, FALSE otherwise. The {key} argument is a string.

Parameters:
- {dict} (table)
- {key} (string)

Return:
(0|1)

haslocaldir([{winnr} [, {tabnr} [, {bufnr}]]]) haslocaldir()

Checks whether the tabpage, window or buffer has set a local working directory. Returns 1 when the window has set a local path via :lcd, or when {winnr} is -1 and the tabpage has set a local path via :tcd, or when {winnr} and {tabnr} are -1 and {bufnr} has set a local path via :bcd, otherwise 0.

Tabs, windows and buffers are identified by their respective numbers, 0 means current tab/window/buffer. Missing {winnr} or {tabnr} implies 0 (missing {bufnr} does not; see below). Thus the following are equivalent:

```
echo haslocaldir()
echo haslocaldir(0)
echo haslocaldir(0, 0)
```

With {winnr} use that window in the current tabpage.
With {winnr} and {tabnr} use the window in that tabpage.
{winnr} is a window-number or window-ID.
If {winnr} is -1 it is ignored, only the tab is resolved.
If {bufnr} is provided, {winnr} and {tabnr} must be -1 and only the buffer is resolved. An argument may be -1 only if all preceding arguments are -1.
Examples of buffer usage:

```
haslocaldir(-1, -1, 0) " Current buf has a local directory?
haslocaldir(-1, -1, 3) " Buf #3 has a local directory?
```

Throw error if the arguments are invalid.
E5000 E5001 E5002 E5006 E5007

Parameters:

- {winnr} (integer?)
- {tabnr} (integer?)
- {bufnr} (integer?)

Return:
(0|1)

hasmapto({what} [, {mode} [, {abbr}]]) hasmapto()

Checks whether a mapping exists whose rhs contains {what}.
Returns TRUE if there is such a mapping in one of the modes
indicated by {mode}.
The arguments {what} and {mode} are strings.
When {abbr} is there and it is TRUE use abbreviations
instead of mappings. Don't forget to specify Insert and/or
Command-line mode.
Both the global mappings and the mappings local to the current
buffer are checked for a match.
If no matching mapping is found FALSE is returned.
The following characters are recognized in {mode}:

n	Normal mode
v	Visual and Select mode
x	Visual mode
s	Select mode
o	Operator-pending mode
i	Insert mode
l	Language-Argument ("r", "f", "t", etc.)
c	Command-line mode

When {mode} is omitted, "nvo" is used.

This function is useful to check if a mapping already exists
to a function in a Vim script. Example:

```
if !hasmapto('\ABCdoit')
   map <Leader>d \ABCdoit
endif
```

This installs the mapping to "\ABCdoit" only if there isn't
already a mapping to "\ABCdoit".

Parameters:
- {what} (any)
- {mode} (string?)
- {abbr} (boolean?)

Return:
(0|1)

histadd({history}, {item}) histadd()

Add the String {item} to the history {history} which can be
one of: hist-names

"cmd"	or ":"	command line history
"search"	or "/"	search pattern history
"expr"	or "="	typed expression history
"input"	or "@"	input line history
"debug"	or ">"	debug command history
empty		the current or last used history

The {history} string does not need to be the whole name, one
character is sufficient.
If {item} does already exist in the history, it will be
shifted to become the newest entry.
The result is a Number: TRUE if the operation was successful,
otherwise FALSE is returned.

Example:

```
call histadd("input", strftime("%Y %b %d"))
let date=input("Enter date: ")
```

This function is not available in the sandbox.

Parameters:
- {history} (string)
- {item} (any)

Return:
(0|1)

histdel({history} [, {item}]) histdel()

Clear {history}, i.e. delete all its entries. See hist-names for the possible values of {history}.

If the parameter {item} evaluates to a String, it is used as a regular expression. All entries matching that expression will be removed from the history (if there are any). Upper/lowercase must match, unless "\c" is used /\c. If {item} evaluates to a Number, it will be interpreted as an index, see :history-indexing. The respective entry will be removed if it exists.

The result is TRUE for a successful operation, otherwise FALSE is returned.

Examples:
Clear expression register history:

```
call histdel("expr")
```

Remove all entries starting with "*" from the search history:

```
call histdel("/", '^\*')
```

The following three are equivalent:

```
call histdel("search", histnr("search"))
call histdel("search", -1)
call histdel("search", '^' .. histget("search", -1) .. '$')
```

To delete the last search pattern and use the last-but-one for the "n" command and 'hlsearch':

```
call histdel("search", -1)
let @/ = histget("search", -1)
```

Parameters:
- {history} (string)

- {item} (any?)

Return:
(0|1)

histget({history} [, {index}]) histget()

Returns an entry from the specified command-line {history}. See hist-names for the possible values of {history}, and :history-indexing for {index}. If there is no such entry, an empty String is returned. When {index} is omitted, the most recent item from the history is used.

Examples:
Redo the second last search from history.

```
execute '/' .. histget("search", -2)
```

Define an Ex command ":H {num}" that supports re-execution of the {num}th entry from the output of :history.

```
command -nargs=1 H execute histget("cmd", 0+<args>)
```

Parameters:
- {history} (string)

- {index} (integer|string?)

Return:
(string)

histnr({history}) histnr()

The result is the Number of the current entry in {history}. See hist-names for the possible values of {history}. If an error occurred, -1 is returned.

Example:

```
let inp_index = histnr("expr")
```

Parameters:
- {history} (string)

Return:
(integer)

hlID({name}) hlID()

Lua: Prefer nvim_get_hl().

Returns the numeric ID of the highlight group with name {name}. When the highlight group doesn't exist, zero is returned.
This can be used to retrieve information about the highlight group. For example, to get the background color of the "Comment" group:

```
echo synIDattr(synIDtrans(hlID("Comment")), "bg")
```

Parameters:
- {name} (string)

Return:
(integer)

hlexists({name}) hlexists()

Lua: Prefer nvim_get_hl().

Checks whether a highlight group called {name} exists. Returns TRUE if the group has been defined in some way. Not necessarily when highlighting has been defined for it, it may also have been used for a syntax item.

Parameters:
- {name} (string|number|boolean|nil)

Return:
(0|1)

hostname() hostname()

Lua: Prefer uv.os_gethostname().

Returns the hostname of the machine on which the Nvim server (not the UI client) is currently running.

Attributes:
api-fast

Return:
(string)

iconv({string}, {from}, {to}) iconv()

Lua: Prefer vim.iconv().

Converts the encoding of {string} from {from} to {to}. Returns the converted String.
When the conversion completely fails an empty string is returned. When some characters could not be converted they are replaced with "?".
The encoding names are whatever the iconv() library function can accept, see ":!man 3 iconv".
Note that Vim uses UTF-8 for all Unicode encodings, conversion from/to UCS-2 is automatically changed to use UTF-8. You cannot use UCS-2 in a string anyway, because of the NUL bytes.

Attributes:
api-fast

Parameters:
- {string} (string)
- {from} (string)
- {to} (string)

Return:
(string)

id({expr}) id()

Returns a String which is a unique identifier of the container type (List, Dict, Blob and Partial). It is guaranteed that for the mentioned types id(v1) ==# id(v2) returns true iff type(v1) == type(v2) && v1 is v2.
Note that v:_null_string, v:_null_list, v:_null_dict and v:_null_blob have the same id() with different types because they are internally represented as NULL pointers.
id() returns a hexadecimal representation of the pointers to the containers (i.e. like 0x994a40), same as printf("%p", {expr}), but it is advised against counting on the exact format of the return value.

It is not guaranteed that id(no_longer_existing_container) will not be equal to some other id(): new containers may

reuse identifiers of the garbage-collected ones.

Parameters:
- {expr} (any)

Return:
(string)

indent({lnum}) indent()

Returns the indent of line {lnum} in the current buffer.
The indent is counted in spaces, the value of 'tabstop' is
relevant. {lnum} is used just like in
getline().
When {lnum} is invalid -1 is returned.

To get or set indent of lines in a string, see vim.text.indent().

Parameters:
- {lnum} (integer|string)

Return:
(integer)

index({object}, {expr} [, {start} [, {ic}]]) index()

Lua: Prefer vim.iter() with Iter:enumerate() and
Iter:find() for lists; result is 1-based, and start, ic,
and Blob semantics differ.

Find {expr} in {object} and return its index. See
indexof() for using a lambda to select the item.

If {object} is a List return the lowest index where the item
has a value equal to {expr}. There is no automatic
conversion, so the String "4" is different from the Number 4.
And the Number 4 is different from the Float 4.0. The value
of 'ignorecase' is not used here, case matters as indicated by
the {ic} argument.

If {object} is a Blob return the lowest index where the byte
value is equal to {expr}.

If {start} is given then start looking at the item with index
{start} (may be negative for an item relative to the end).

When {ic} is given and it is TRUE, ignore case. Otherwise
case must match.

-1 is returned when {expr} is not found in {object}.
Example:

```
let idx = index(words, "the")
if index(numbers, 123) >= 0
  " ...
endif
```

Parameters:
- {object} (any)
- {expr} (any)
- {start} (integer?)
- {ic} (boolean?)

Return:
(integer)

indexof({object}, {expr} [, {opts}]) indexof()

Lua: Prefer vim.iter() with Iter:enumerate() and
Iter:find() for list predicates; result is 1-based, and
startidx and Blob semantics differ.

Returns the index of an item in {object} where {expr} is
v:true. {object} must be a List or a Blob.

If {object} is a List, evaluate {expr} for each item in the
List until the expression is v:true and return the index of
this item.

If {object} is a Blob evaluate {expr} for each byte in the
Blob until the expression is v:true and return the index of
this byte.

{expr} must be a string or Funcref.

If {expr} is a string: If {object} is a List, inside
{expr} v:key has the index of the current List item and
v:val has the value of the item. If {object} is a Blob,

inside {expr} v:key has the index of the current byte and
v:val has the byte value.

If {expr} is a Funcref it must take two arguments:
1. the key or the index of the current item.

2. the value of the current item.

The function must return TRUE if the item is found and the
search should stop.

The optional argument {opts} is a Dict and supports the
following items:
    startidx   start evaluating {expr} at the item with this
                index; may be negative for an item relative to
                the end
Returns -1 when {expr} evaluates to v:false for all the items.
Example:

```
let l = [#{n: 10}, #{n: 20}, #{n: 30}]
echo indexof(l, "v:val.n == 20")
echo indexof(l, {i, v -> v.n == 30})
echo indexof(l, "v:val.n == 20", #{startidx: 1})
```

Parameters:
- {object} (any)

- {expr} (any)

- {opts} (table?)

Return:
(integer)

input({prompt} [, {text} [, {completion}]]) input()

Lua: Prefer vim.ui.input() for callback-based input.

Parameters:
- {prompt} (string)

- {text} (string?)

- {completion} (string?)

Return:
(string)

input({opts})

Lua: Prefer vim.ui.input() for callback-based input.

Prompts the user to enter text on the command-line, and
returns the text as a String. The {prompt} argument is either
a prompt string, or a blank string (for no prompt). A '\n'
can be used in the prompt to start a new line.

In the second form it accepts a single dictionary with the
following keys, any of which may be omitted:

Key	Default	Description
prompt	""	Same as {prompt} in the first form.
default	""	Same as {text} in the first form.
completion	nothing	Same as {completion} in the first form.
cancelreturn	""	The value returned when the dialog is cancelled.
highlight	nothing	Highlight handler: Funcref.

The highlighting set with :echohl is used for the prompt.
The input is entered just like a command-line, with the same
editing commands and mappings. There is a separate history
for lines typed for input().
Example:

```
if input("Coffee or beer? ") == "beer"
  echo "Cheers!"
endif
```

If the optional {text} argument is present and not empty, this
is used for the default reply, as if the user typed this.
Example:

```
let color = input("Color? ", "white")
```

The optional {completion} argument specifies the type of
completion supported for the input. Without it completion is
not performed. The supported completion types are the same as

that can be supplied to a user-defined command using the
"-complete=" argument. Refer to :command-completion for
more information. Example:

```
let fname = input("File: ", "", "file")
```

input()-highlight E5400 E5402

The optional highlight key allows specifying function which
will be used for highlighting user input. This function
receives user input as its only argument and must return
a list of 3-tuples [hl_start_col, hl_end_col + 1, hl_group]
where
        hl_start_col is the first highlighted column,
        hl_end_col is the last highlighted column (+ 1!),
        hl_group is :hi group used for highlighting.
E5403 E5404 E5405 E5406

Both hl_start_col and hl_end_col + 1 must point to the start
of the multibyte character (highlighting must not break
multibyte characters), hl_end_col + 1 may be equal to the
input length. Start column must be in range [0, len(input)),
end column must be in range (hl_start_col, len(input)],
sections must be ordered so that next hl_start_col is greater
then or equal to previous hl_end_col.

Example (try some input with parentheses):

```
highlight RBP1 guibg=Red ctermbg=red
highlight RBP2 guibg=Yellow ctermbg=yellow
highlight RBP3 guibg=Green ctermbg=green
highlight RBP4 guibg=Blue ctermbg=blue
let g:rainbow_levels = 4
function! RainbowParens(cmdline)
  let ret = []
  let i = 0
  let lvl = 0
  while i < len(a:cmdline)
    if a:cmdline[i] is# '('
      call add(ret, [i, i + 1, 'RBP' .. ((lvl % g:rainbow_levels) + 1)])
      let lvl += 1
    elseif a:cmdline[i] is# ')'
      let lvl -= 1
      call add(ret, [i, i + 1, 'RBP' .. ((lvl % g:rainbow_levels) + 1)])
    endif
    let i += 1
  endwhile
  return ret
endfunction
call input({'prompt':'>','highlight':'RainbowParens'})
```

Highlight function is called at least once for each new
displayed input string, before command-line is redrawn. It is
expected that function is pure for the duration of one input()
call, i.e. it produces the same output for the same input, so
output may be memoized. Function is run like under :silent
modifier. If the function causes any errors, it will be
skipped for the duration of the current input() call.

Highlighting is disabled if command-line contains arabic
characters.

NOTE: This function must not be used in a startup file, for
the versions that only run in GUI mode (e.g., the Win32 GUI).
Note: When input() is called from within a mapping it will
consume remaining characters from that mapping, because a
mapping is handled like the characters were typed.
Use inputsave() before input() and inputrestore()
after input() to avoid that. Another solution is to avoid
that further characters follow in the mapping, e.g., by using
:execute or :normal.

Example with a mapping:

```
nmap \x :call GetFoo()<CR>:exe "/" .. Foo<CR>
function GetFoo()
  call inputsave()
  let g:Foo = input("enter search pattern: ")
  call inputrestore()
endfunction
```

Parameters:
- {opts} (table)

Return:
(string)

inputlist({textlist}) inputlist()

Lua: Prefer vim.ui.select() for simple selection menus;
callback, returned item, and out-of-range semantics differ.

Displays a list of strings and prompts the user to select
one by entering a number. {textlist} must be a List of

strings. Returns the number the user entered.
The user can also select an item by clicking on it with the
mouse, if the mouse is enabled in the command line ('mouse' is
"a" or includes "c"). For the first string 0 is returned.
When clicking above the first item a negative number is
returned. When clicking on the prompt one more than the
length of {textlist} is returned.
Make sure {textlist} has less than 'lines' entries, otherwise
it won't work. It's a good idea to put the entry number at
the start of the string. And put a prompt in the first item.
Example:

```
let color = inputlist(['Select color:', '1. red',
        \ '2. green', '3. blue'])
```

Parameters:
- {textlist} (string[])

Return:
(any)

inputrestore() inputrestore()

Restore typeahead that was saved with a previous inputsave().
Should be called the same number of times inputsave() is
called. Calling it more often is harmless though.
Returns TRUE when there is nothing to restore, FALSE
otherwise.

Return:
(integer)

inputsave() inputsave()

Preserve typeahead (also from mappings) and clear it, so that
a following prompt gets input from the user. Should be
followed by a matching inputrestore() after the prompt. Can
be used several times, in which case there must be just as
many inputrestore() calls.
Returns TRUE when out of memory, FALSE otherwise.

Return:
(integer)

inputsecret({prompt} [, {text}]) inputsecret()

This function acts much like the input() function with but
two exceptions:
a) the user's response will be displayed as a sequence of
asterisks ("*") thereby keeping the entry secret, and
b) the user's response will not be recorded on the input
history stack.
The result is a String, which is whatever the user actually
typed on the command-line in response to the issued prompt.
NOTE: Command-line completion is not supported.

Parameters:
- {prompt} (string)
- {text} (string?)

Return:
(string)

insert({object}, {item} [, {idx}]) insert()

Lua: Prefer table.insert() for lists; blob insertion and
negative indexes differ.

When {object} is a List or a Blob insert {item} at the start
of it.

If {idx} is specified insert {item} before the item with index
{idx}. If {idx} is zero it goes before the first item, just
like omitting {idx}. A negative {idx} is also possible, see
list-index. -1 inserts just before the last item.

Returns the resulting List or Blob. Examples:

```
let mylist = insert([2, 3, 5], 1)
call insert(mylist, 4, -1)
call insert(mylist, 6, len(mylist))
```

The last example can be done simpler with add().
Note that when {item} is a List it is inserted as a single
item. Use extend() to concatenate Lists.

Parameters:
- {object} (any)

- {item} (any)

- {idx} (integer?)

Return:
(any)

interrupt() interrupt()

Interrupt script execution. It works more or less like the user typing CTRL-C, most commands won't execute and control returns to the user. This is useful to abort execution from lower down, e.g. in an autocommand. Example:

```
function s:check_typoname(file)
   if fnamemodify(a:file, ':t') == '['
       echomsg 'Maybe typo'
       call interrupt()
   endif
endfunction
au BufWritePre * call s:check_typoname(expand('<amatch>'))
```

Return:
(any)

invert({expr}) invert()

Lua: Prefer bit.bnot().

Bitwise invert. The argument is converted to a number. A List, Dict or Float argument causes an error. Example:

```
let bits = invert(bits)
```

Parameters:
- {expr} (integer)

Return:
(integer)

isabsolutepath({path}) isabsolutepath()

Checks whether {path} is an absolute path. Returns TRUE if so, FALSE otherwise.
On Unix, a path is considered absolute when it starts with '/'.
On MS-Windows, it is considered absolute when it starts with an optional drive prefix and is followed by a '\' or '/'. UNC paths are always absolute.
Example:

```
echo isabsolutepath('/usr/share/')      " 1
echo isabsolutepath('./foobar')         " 0
echo isabsolutepath('C:\Windows')       " 1
echo isabsolutepath('foobar')           " 0
echo isabsolutepath('\\remote\file')    " 1
```

Attributes:
api-fast

Parameters:
- {path} (string)

Return:
(0|1)

isdirectory({directory}) isdirectory()

Lua: Prefer uv.fs_stat() and check type == "directory".

Returns TRUE if {directory} exists, or FALSE if it doesn't exist or isn't a directory. {directory} is any expression, which is used as a String.

Attributes:
api-fast

Parameters:
- {directory} (string)

Return:
(0|1)

isinf({expr}) isinf()

Lua: Prefer
expr == math.huge and 1 or expr == -math.huge and -1 or 0.

Return 1 if {expr} is a positive infinity, or -1 a negative
infinity, otherwise 0.

```
echo isinf(1.0 / 0.0)
```

```
1
```

```
echo isinf(-1.0 / 0.0)
```

```
-1
```

Parameters:
- {expr} (number)

Return:
(1|0|-1)

islocked({expr}) islocked() E786

Returns TRUE if {expr} is the name of a locked variable,
else FALSE.
The string argument {expr} must be the name of a variable,
List item or Dictionary entry, not the variable itself!
Example:

```
let alist = [0, ['a', 'b'], 2, 3]
lockvar 1 alist
echo islocked('alist')          " 1
echo islocked('alist[1]')       " 0
```

When {expr} is a variable that does not exist you get an error
message. Use exists() to check for existence.

Parameters:
- {expr} (any)

Return:
(0|1)

isnan({expr}) isnan()

Lua: Prefer expr ~= expr.

Return TRUE if {expr} is a float with value NaN.

```
echo isnan(0.0 / 0.0)
```

```
1
```

Parameters:
- {expr} (number)

Return:
(0|1)

items({expr}) items()

Lua: Prefer pairs() or ipairs().

Return a List with all key/index and value pairs of {expr}.
Each List item is a list with two items:
- for a Dict: the key and the value

- for a List, Blob or String: the index and the value

The returned List is in arbitrary order for a Dict,
otherwise it's in ascending order of the index.

Also see keys() and values().

Example:

```
let mydict = #{a: 'red', b: 'blue'}
for [key, value] in items(mydict)
   echo $"{key} = {value}"
endfor
echo items([1, 2, 3])
echo items("foobar")
echo items(0z0102)
```

Parameters:
- {expr} (table|string)

Return:
(any)

jobpid({job}) jobpid()

Lua: Prefer vim.system() object .pid; job-id and channel
semantics differ.

Return the PID (process id) of job-id {job}.

Parameters:

- {job} (integer)

Return:

(integer)

jobresize({job}, {width}, {height}) jobresize()

Resize the pseudo terminal window of job-id {job} to {width}
columns and {height} rows.
Fails if the job was not started with "pty":v:true.

Parameters:

- {job} (integer)
- {width} (integer)
- {height} (integer)

Return:

(any)

jobstart({cmd} [, {opts}]) jobstart()

Lua: Prefer vim.system() for simple processes; RPC,
PTY/term, streaming callbacks, and shell-string behavior
differ.

Spawns {cmd} as a job.
If {cmd} is a List it runs directly (no 'shell').
If {cmd} is a String it runs in the 'shell', like this:

```
call jobstart(split(&shell) + split(&shellcmdflag) + ['{cmd}'])
```

(See shell-unquoting for details.)

Example: start a job and handle its output:

```
call jobstart(['nvim', '-h'], {'on_stdout':{j,d,e->append(line('.'),d)}})
```

Example: start a job in a terminal connected to the current buffer:

```
call jobstart(['nvim', '-h'], {'term':v:true})
```

Returns job-id on success, 0 on invalid arguments (or job
table is full), -1 if {cmd}[0] or 'shell' is not executable.
The returned job-id is a valid channel-id representing the
job's stdio streams. Use chansend() (or rpcnotify() and
rpcrequest() if "rpc" was enabled) to send data to stdin and
chanclose() to close the streams without stopping the job.

See job-control and RPC.

NOTE: on Windows if {cmd} is a List:

- cmd[0] must be an executable (not a "built-in"). If it is

  in $PATH it can be called by name, without an extension:

  ```
  call jobstart(['ping', 'neovim.io'])
  ```

  If it is a full or partial path, extension is required:

  ```
  call jobstart(['System32\ping.exe', 'neovim.io'])
  ```

- {cmd} is collapsed to a string of quoted args as expected

  by CommandLineToArgvW https://msdn.microsoft.com/bb776391
  unless cmd[0] is some form of "cmd.exe".

jobstart-env

The job environment is initialized as follows:

$NVIM	is set to v:servername of the parent Nvim
$NVIM_LISTEN_ADDRESS	is unset
$NVIM_LOG_FILE	is unset
$VIM	is unset
$VIMRUNTIME	is unset

You can set these with the env option.

jobstart-options

{opts} is a dictionary with these keys:

clear_env: (boolean) env defines the job environment exactly, instead of merging current environment.
cwd: (string, default=|current-directory|) Working directory of the job.
detach: (boolean) Detach the job process: it will not be killed when Nvim exits. If the process exits before Nvim, on_exit will be invoked.
env: (dict) Map of environment variable name:value pairs extending (or replace with "clear_env") the current environment. jobstart-env
height: (number) Height of the pty terminal.
on_exit: (function) Callback invoked when the job exits.
on_stdout: (function) Callback invoked when the job emits stdout data.
on_stderr: (function) Callback invoked when the job emits stderr data.
overlapped: (boolean) Sets FILE_FLAG_OVERLAPPED for the stdio passed to the child process. Only on MS-Windows; ignored on other platforms.
pty: (boolean) Connect the job to a new pseudo terminal, and its streams to the master file descriptor. on_stdout receives all output, on_stderr is ignored. **Note:** if the child writes a query (DA1, OSC, …), it may hang or timeout waiting for a response! To avoid that, on_stdout should reply via nvim_chan_send() on the child's stdin. See terminal-start terminal-concepts
rpc: (boolean) Use msgpack-rpc to communicate with the job over stdio. Then on_stdout is ignored, but on_stderr can still be used.
stderr_buffered: (boolean) Collect data until EOF (stream closed) before invoking on_stderr. channel-buffered
stdout_buffered: (boolean) Collect data until EOF (stream closed) before invoking on_stdout. channel-buffered
stdin: (string) Either "pipe" (default) to connect the job's stdin to a channel or "null" to disconnect stdin.
term: (boolean) Spawns {cmd} in a new pseudo-terminal session connected to the current (unmodified) buffer. Implies "pty". Defaults "height" and "width" to the current window dimensions. Defaults $TERM to "xterm-256color".
width: (number) Width of the pty pseudo-terminal.

{opts} is passed as self dictionary to the callback; the caller may set other keys to pass application-specific data.

Returns:

- channel-id on success
- 0 on invalid arguments
- -1 if {cmd}[0] is not executable.

See also job-control, channel, msgpack-rpc.

Parameters:

- {cmd} (string|string[])
- {opts} (table?)

Return:

(integer)

jobstop({id}) jobstop()

Lua: Prefer SystemObj:kill() on a vim.system() object; job-id semantics differ.

Stop job-id {id} by sending SIGTERM to the job process. If the process does not terminate after a timeout then SIGKILL will be sent. When the job terminates its on_exit handler (if any) will be invoked.
See job-control.

Returns 1 for valid job id, 0 for invalid id, including jobs have exited or stopped.

Parameters:

- {id} (integer)

Return:

(integer)

jobwait({jobs} [, {timeout}]) jobwait()

Lua: Prefer SystemObj:wait() on a vim.system() object;
list input and status values differ.

Waits for jobs and their on_exit handlers to complete.

{jobs} is a List of job-ids to wait for.
{timeout} is the maximum waiting time in milliseconds. If
omitted or -1, wait forever.

Timeout of 0 can be used to check the status of a job:

```
let running = jobwait([{job-id}], 0)[0] == -1
```

During jobwait() callbacks for jobs not in the {jobs} list may
be invoked. The screen will not redraw unless :redraw is
invoked by a callback.

Returns a list of len({jobs}) integers, where each integer is
the status of the corresponding job:
        Exit-code, if the job exited
        -1 if the timeout was exceeded
        -2 if the job was interrupted (by CTRL-C)
        -3 if the job-id is invalid

Parameters:
- {jobs} (integer[])

- {timeout} (integer?)

Return:
  (integer[])

join({list} [, {sep}]) join()

Lua: Prefer table.concat() for string lists; non-string
values stringify differently.

Join the items in {list} together into one String.
When {sep} is specified it is put in between the items. If
{sep} is omitted a single space is used.
Note that {sep} is not added at the end. You might want to
add it there too:

```
let lines = join(mylist, "\n") .. "\n"
```

String items are used as-is. Lists and Dictionaries are
converted into a string like with string().
The opposite function is split().

Parameters:
- {list} (any[])

- {sep} (string?)

Return:
  (string)

json_decode({expr}) json_decode()

Lua: Prefer vim.json.decode().

Convert {expr} from JSON object. Accepts readfile()-style
list as the input, as well as regular string. May output any
Vim value. In the following cases it will output
msgpack-special-dict:
1. Dictionary contains duplicate key.

2. String contains NUL byte. Two special dictionaries: for

    dictionary and for string will be emitted in case string
    with NUL byte was a dictionary key.

Note: function treats its input as UTF-8 always. The JSON
standard allows only a few encodings, of which UTF-8 is
recommended and the only one required to be supported.
Non-UTF-8 characters are an error.

Parameters:
- {expr} (any)

Return:
  (any)

json_encode({expr}) json_encode()

Lua: Prefer vim.json.encode().

Convert {expr} into a JSON string. Accepts
msgpack-special-dict as the input. Will not convert

Funcrefs, mappings with non-string keys (can be created as msgpack-special-dict), values with self-referencing containers, strings which contain non-UTF-8 characters, pseudo-UTF-8 strings which contain codepoints reserved for surrogate pairs (such strings are not valid UTF-8 strings). Non-printable characters are converted into "\u1234" escapes or special escapes like "\t", other are dumped as-is. Blobs are converted to arrays of the individual bytes.

Parameters:
- {expr} (any)

Return:
(string)

keys({dict}) keys()

Lua: Prefer vim.tbl_keys().

Return a List with all the keys of {dict}. The List is in arbitrary order. Also see items() and values().

Parameters:
- {dict} (table)

Return:
(string[])

keytrans({string}) keytrans()

Turn the internal byte representation of keys into a form that can be used for :map. E.g.

```
let xx = "\<C-Home>"
echo keytrans(xx)
```

<C-Home>

Attributes:
api-fast

Parameters:
- {string} (string)

Return:
(string)

len({expr}) len() E701

Lua: Prefer Lua # operator for strings and lists or #vim.tbl_keys(expr) for dicts.

Returns the length of the argument.
When {expr} is a String or a Number the length in bytes is used, as with strlen().
When {expr} is a List the number of items in the List is returned.
When {expr} is a Blob the number of bytes is returned.
When {expr} is a Dictionary the number of entries in the Dictionary is returned.
Otherwise an error is given and returns zero.

Parameters:
- {expr} (any[])

Return:
(integer)

libcall({libname}, {funcname}, {argument}) libcall() E364 E368

Lua: Prefer package.loadlib() or ffi.load().

Call function {funcname} in the run-time library {libname} with single argument {argument}.
This is useful to call functions in a library that you especially made to be used with Vim. Since only one argument is possible, calling standard library functions is rather limited.
The result is the String returned by the function. If the function returns NULL, this will appear as an empty string "" to Vim.
If the function returns a number, use libcallnr()!
If {argument} is a number, it is passed to the function as an int; if {argument} is a string, it is passed as a null-terminated string.

libcall() allows you to write your own 'plug-in' extensions to Vim without having to recompile the program. It is NOT a means to call system functions! If you try to do so Vim will very probably crash.

For Win32, the functions you write must be placed in a DLL and use the normal C calling convention (NOT Pascal which is used in Windows System DLLs). The function must take exactly

one parameter, either a character pointer or a long integer, and must return a character pointer or NULL. The character pointer returned must point to memory that will remain valid after the function has returned (e.g. in static data in the DLL). If it points to allocated memory, that memory will leak away. Using a static buffer in the function should work, it's then freed when the DLL is unloaded.

WARNING: If the function returns a non-valid pointer, Vim may crash! This also happens if the function returns a number, because Vim thinks it's a pointer.
For Win32 systems, {libname} should be the filename of the DLL without the ".DLL" suffix. A full path is only required if the DLL is not in the usual places.
For Unix: When compiling your own plugins, remember that the object code must be compiled as position-independent ('PIC').
Examples:

```
echo libcall("libc.so", "getenv", "HOME")
```

Parameters:
- {libname} (string)
- {funcname} (string)
- {argument} (any)

Return:
(any)

libcallnr({libname}, {funcname}, {argument}) libcallnr()

Lua: Prefer package.loadlib() or ffi.load().

Just like libcall(), but used for a function that returns an int instead of a string.
Examples:

```
echo libcallnr("/usr/lib/libc.so", "getpid", "")
call libcallnr("libc.so", "printf", "Hello World!\n")
call libcallnr("libc.so", "sleep", 10)
```

Parameters:
- {libname} (string)
- {funcname} (string)
- {argument} (any)

Return:
(any)

line({expr} [, {winid}]) line()

Lua: Prefer nvim_win_get_cursor() for "." or nvim_buf_line_count() for "$"; marks, lists, and other position expressions differ.

See getpos() for accepted positions.

To get the column number use col(). To get both use getpos().

With the optional {winid} argument the values are obtained for that window instead of the current window.

Returns 0 for invalid values of {expr} and {winid}.

Examples:

```
echo line(".")                  " line number of the cursor
echo line(".", winid)           " idem, in window "winid"
echo line("'t")                 " line number of mark t
echo line("'" .. marker)        " line number of mark marker
```

To jump to the last known position when opening a file see last-position-jump.

Parameters:
- {expr} (string|integer[])
- {winid} (integer?)

Return:
(integer)

line2byte({lnum}) line2byte()

Lua: Prefer nvim_buf_get_offset() with lnum - 1;
'fileformat' and invalid-line semantics differ.

Return the byte count from the start of the buffer for line
{lnum}. This includes the end-of-line character, depending on
the 'fileformat' option for the current buffer. The first
line returns 1. UTF-8 encoding is used, 'fileencoding' is
ignored. This can also be used to get the byte count for the
line just below the last line:

```
echo line2byte(line("$") + 1)
```

This is the buffer size plus one. If 'fileencoding' is empty
it is the file size plus one. {lnum} is used like with
getline(). When {lnum} is invalid -1 is returned.
Also see byte2line(), go and :goto.

Parameters:
- {lnum} (integer|string)

Return:
(integer)

lispindent({lnum}) lispindent()

Get the amount of indent for line {lnum} according the lisp
indenting rules, as with 'lisp'.
The indent is counted in spaces, the value of 'tabstop' is
relevant. {lnum} is used just like in getline().
When {lnum} is invalid, -1 is returned.

Parameters:
- {lnum} (integer|string)

Return:
(integer)

list2blob({list}) list2blob()

Return a Blob concatenating all the number values in {list}.
Examples:

```
echo list2blob([1, 2, 3, 4])    " returns 0z01020304
echo list2blob([])              " returns 0z
```

Returns an empty Blob on error. If one of the numbers is
negative or more than 255 error E1239 is given.

blob2list() does the opposite.

Parameters:
- {list} (any[])

Return:
(string)

list2str({list} [, {utf8}]) list2str()

Converts each codepoint in {list} to a UTF-8 character and
returns the concatenated string. Examples:

```
echo list2str([32])             " returns " "
echo list2str([65, 66, 67])     " returns "ABC"
```

The same can be done (slowly) with:

```
echo join(map(list, {nr, val -> nr2char(val)}), '')
```

str2list() does the opposite.

UTF-8 encoding is always used, {utf8} option has no effect,
and exists only for backwards-compatibility.
With UTF-8 composing characters work as expected:

```
echo list2str([97, 769])        " returns "á"
```

Returns an empty string on error.

Parameters:
- {list} (any[])
- {utf8} (boolean?)

Return:
(string)

localtime() localtime()

Lua: Prefer os.time().

Return the current time, measured as seconds since 1st Jan 1970. See also strftime(), strptime() and getftime().

Return:
(integer)

log({expr}) log()

Lua: Prefer math.log().

Return the natural logarithm (base e) of {expr} as a Float. {expr} must evaluate to a Float or a Number in the range (0, inf].
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo log(10)
```

2.302585

```
echo log(exp(5))
```

5.0

Parameters:
- {expr} (number)

Return:
(number)

log10({expr}) log10()

Lua: Prefer math.log10().

Return the logarithm of Float {expr} to base 10 as a Float. {expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo log10(1000)
```

3.0

```
echo log10(0.01)
```

-2.0

Parameters:
- {expr} (number)

Return:
(number)

luaeval({expr} [, {expr}]) luaeval()

Lua: Prefer plain Lua expressions and values directly.

Evaluate Lua expression {expr} and return its result converted to Vim data structures. See lua-eval for details.

See also v:lua-call.

Parameters:
- {expr} (string)
- {expr1} (any[]?)

Return:
(any)

map({expr1}, {expr2}) map()

Lua: Prefer vim.tbl_map() for array-like tables; dict, string, blob, and in-place behavior differ.

{expr1} must be a List, String, Blob or Dictionary.
When {expr1} is a List or Dictionary, replace each item in {expr1} with the result of evaluating {expr2}.
For a Blob each byte is replaced.
For a String, each character, including composing characters, is replaced.
If the item type changes you may want to use mapnew() to create a new List or Dictionary.

{expr2} must be a String or Funcref.

If {expr2} is a String, inside {expr2} v:val has the value of the current item. For a Dictionary v:key has the key of the current item and for a List v:key has the index of the current item. For a Blob v:key has the index of the

current byte. For a String v:key has the index of the
current character.
Example:

```
call map(mylist, '"> " .. v:val .. " <"')
```

This puts "> " before and " <" after each item in "mylist".

Note that {expr2} is the result of an expression and is then
used as an expression again. Often it is good to use a
literal-string to avoid having to double backslashes. You
still have to double single (') quotes, though.

If {expr2} is a Funcref it is called with two arguments:
1. The key or the index of the current item.

2. the value of the current item.

The function must return the new value of the item. Example
that changes each value by "key-value":

```
func KeyValue(key, val)
  return a:key .. '-' .. a:val
endfunc
call map(myDict, function('KeyValue'))
```

It is shorter when using a lambda:

```
call map(myDict, {key, val -> key .. '-' .. val})
```

If you do not use "val" you can leave it out:

```
call map(myDict, {key -> 'item: ' .. key})
```

If you do not use "key" you can use a short name:

```
call map(myDict, {_, val -> 'item: ' .. val})
```

The operation is done in-place for a List and Dictionary.
If you want it to remain unmodified make a copy first:

```
let tlist = map(copy(mylist), ' v:val .. "\t"')
```

Returns {expr1}, the List or Dictionary that was filtered,
or a new Blob or String.
When an error is encountered while evaluating {expr2} no
further items in {expr1} are processed.
When {expr2} is a Funcref errors inside a function are
ignored, unless it was defined with the "abort" flag.

Parameters:

- {expr1} (string|table|any[])
- {expr2} (string|function)

Return:

(any)

maparg({name} [, {mode} [, {abbr} [, {dict}]]]) maparg()

When {dict} is omitted or zero: Return the rhs of mapping
{name} in mode {mode}. The returned String has special
characters translated like in the output of the ":map" command
listing. When {dict} is TRUE a dictionary is returned, see
below. To get a list of all mappings see maplist().

When there is no mapping for {name}, an empty String is
returned if {dict} is FALSE, otherwise returns an empty Dict.
When the mapping for {name} is empty, then "<Nop>" is
returned.

The {name} can have special key names, like in the ":map"
command.

{mode} can be one of these strings:

"n"	Normal
"v"	Visual (including Select)
"o"	Operator-pending
"i"	Insert
"c"	Cmd-line
"s"	Select
"x"	Visual
"l"	langmap language-mapping
"t"	Terminal
""	Normal, Visual and Operator-pending

When {mode} is omitted, the modes for "" are used.

When {abbr} is there and it is TRUE use abbreviations
instead of mappings.

When {dict} is TRUE, return a dictionary describing the
mapping, with these items: mapping-dict

```
  "lhs"      The {lhs} of the mapping as it would be typed
  "lhsraw"   The {lhs} of the mapping as raw bytes
  "lhsrawalt" The {lhs} of the mapping as raw bytes, alternate
              form, only present when it differs from "lhsraw"
  "rhs"      The {rhs} of the mapping as typed.
  "callback" Lua function, if RHS was defined as such.
  "silent"   1 for a :map-silent mapping, else 0.
  "noremap"  1 if the {rhs} of the mapping is not remappable.
  "script"   1 if mapping was defined with <script>.
  "expr"     1 for an expression mapping (:map-<expr>).
  "buffer"   1 for a buffer local mapping (:map-local).
  "mode"     Modes for which the mapping is defined.  In
             addition to the modes mentioned above, these
             characters will be used:
             " "     Normal, Visual and Operator-pending
             "!"     Insert and Commandline mode
                     (mapmode-ic)
  "sid"      The script local ID, used for <sid> mappings
             (<SID>).  Negative for special contexts.
  "scriptversion"  The version of the script, always 1.
  "lnum"     The line number in "sid", zero if unknown.
  "nowait"   Do not wait for other, longer mappings.
             (:map-<nowait>).
  "abbr"     True if this is an abbreviation.
  "mode_bits" Nvim's internal binary representation of "mode".
             mapset() ignores this; only "mode" is used.
             See maplist() for usage examples.  The values
             are from src/nvim/state_defs.h and may change in
             the future.
```

The dictionary can be used to restore a mapping with
mapset().

The mappings local to the current buffer are checked first,
then the global mappings.
This function can be used to map a key even when it's already
mapped, and have it do the original mapping too. Sketch:

```
exe 'nnoremap <Tab> ==' .. maparg('<Tab>', 'n')
```

Parameters:

- {name} (string)
- {mode} (string?)
- {abbr} (boolean?)
- {dict} (false?)

Return:

(string)

mapcheck({name} [, {mode} [, {abbr}]]) mapcheck()

Check if there is a mapping that matches with {name} in mode
{mode}. See maparg() for {mode} and special names in
{name}.
When {abbr} is there and it is non-zero use abbreviations
instead of mappings.
A match happens with a mapping that starts with {name} and
with a mapping which is equal to the start of {name}.

matches mapping "a"	"ab"	"abc"	
mapcheck("a")	yes	yes	yes
mapcheck("abc")	yes	yes	yes
mapcheck("ax")	yes	no	no
mapcheck("b")	no	no	no

The difference with maparg() is that mapcheck() finds a
mapping that matches with {name}, while maparg() only finds a
mapping for {name} exactly.
When there is no mapping that starts with {name}, an empty
String is returned. If there is one, the RHS of that mapping
is returned. If there are several mappings that start with
{name}, the RHS of one of them is returned. This will be
"<Nop>" if the RHS is empty.
The mappings local to the current buffer are checked first,
then the global mappings.
This function can be used to check if a mapping can be added
without being ambiguous. Example:

```
if mapcheck("_vv") == ""
   map _vv :set guifont=7x13<CR>
endif
```

This avoids adding the "_vv" mapping when there already is a mapping for "_v" or for "_vvv".

Parameters:
- {name} (string)
- {mode} (string?)
- {abbr} (boolean?)

Return:
(any)

maplist([{abbr}]) maplist()

Returns a List of all mappings. Each List item is a Dict, the same as what is returned by maparg(), see mapping-dict. When {abbr} is there and it is TRUE use abbreviations instead of mappings.

Example to show all mappings with "MultiMatch" in rhs:

```
echo maplist()->filter({_, m ->
        \ match(get(m, 'rhs', ''), 'MultiMatch') >= 0
        \ })
```

It can be tricky to find mappings for particular :map-modes. mapping-dict's "mode_bits" can simplify this. For example, the mode_bits for Normal, Insert or Command-line modes are 0x19. To find all the mappings available in those modes you can do:

```
let saved_maps = []
for m in maplist()
    if and(m.mode_bits, 0x19) != 0
        eval saved_maps->add(m)
    endif
endfor
echo saved_maps->mapnew({_, m -> m.lhs})
```

The values of the mode_bits are defined in Nvim's src/nvim/state_defs.h file and they can be discovered at runtime using :map-commands and "maplist()". Example:

```
omap xyzzy <Nop>
let op_bit = maplist()->filter(
    \ {_, m -> m.lhs == 'xyzzy'})[0].mode_bits
ounmap xyzzy
echo printf("Operator-pending mode bit: 0x%x", op_bit)
```

Parameters:
- {abbr} (0|1?)

Return:
(table[])

mapnew({expr1}, {expr2}) mapnew()

Lua: Prefer vim.tbl_map() for tables; string, blob, and v:key callback behavior differ.

Like map() but instead of replacing items in {expr1} a new List or Dictionary is created and returned. {expr1} remains unchanged. Items can still be changed by {expr2}, if you don't want that use deepcopy() first.

Parameters:
- {expr1} (any)
- {expr2} (any)

Return:
(any)

mapset({mode}, {abbr}, {dict}) mapset()

mapset({dict})

Restore a mapping from a dictionary, possibly returned by maparg() or maplist(). A buffer mapping, when dict.buffer is true, is set on the current buffer; it is up to the caller to ensure that the intended buffer is the current buffer. This feature allows copying mappings from one buffer to

another.
The dict.mode value may restore a single mapping that covers
more than one mode, like with mode values of '!', ' ', "nox",
or 'v'. E1276

In the first form, {mode} and {abbr} should be the same as
for the call to maparg(). E460
{mode} is used to define the mode in which the mapping is set,
not the "mode" entry in {dict}.
Example for saving and restoring a mapping:

```
let save_map = maparg('K', 'n', 0, 1)
nnoremap K somethingelse
" ...
call mapset('n', 0, save_map)
```

Note that if you are going to replace a map in several modes,
e.g. with :map!, you need to save/restore the mapping for
all of them, when they might differ.

In the second form, with {dict} as the only argument, mode
and abbr are taken from the dict.
Example:

```
let save_maps = maplist()->filter(
                      \ {_, m -> m.lhs == 'K'})
nnoremap K somethingelse
cnoremap K somethingelse2
" ...
unmap K
for d in save_maps
    call mapset(d)
endfor
```

Parameters:
- {dict} (table<string,any>)

Return:
(any)

match({expr}, {pat} [, {start} [, {count}]]) match()

When {expr} is a List then this returns the index of the
first item where {pat} matches. Each item is used as a
String, Lists and Dictionaries are used as echoed.

Otherwise, {expr} is used as a String. The result is a
Number, which gives the index (byte offset) in {expr} where
{pat} matches.

A match at the first character or List item returns zero.
If there is no match -1 is returned.

For getting submatches see matchlist().
Example:

```
echo match("testing", "ing")    " results in 4
echo match([1, 'x'], '\a')      " results in 1
```

See string-match for how {pat} is used.

strpbrk()

Vim doesn't have a strpbrk() function. But you can do:

```
let sepidx = match(line, '[.,;: \t]')
```

strcasestr()

Vim doesn't have a strcasestr() function. But you can add
"\c" to the pattern to ignore case:

```
let idx = match(haystack, '\cneedle')
```

If {start} is given, the search starts from byte index
{start} in a String or item {start} in a List.
The result, however, is still the index counted from the
first character/item. Example:

```
echo match("testing", "ing", 2)
```

result is again "4".

```
echo match("testing", "ing", 4)
```

result is again "4".

```
echo match("testing", "t", 2)
```

result is "3".
For a String, if {start} > 0 then it is like the string starts
{start} bytes later, thus "^" will match at {start}. Except
when {count} is given, then it's like matches before the

{start} byte are ignored (this is a bit complicated to keep it
backwards compatible).
For a String, if {start} < 0, it will be set to 0. For a list
the index is counted from the end.
If {start} is out of range ({start} > strlen({expr}) for a
String or {start} > len({expr}) for a List) -1 is returned.

When {count} is given use the {count}th match. When a match
is found in a String the search for the next one starts one
character further. Thus this example results in 1:

```
echo match("testing", "..", 0, 2)
```

In a List the search continues in the next item.
Note that when {count} is added the way {start} works changes,
see above.

match-pattern

See pattern for the patterns that are accepted.
The 'ignorecase' option is used to set the ignore-caseness of
the pattern. 'smartcase' is NOT used. The matching is always
done like 'magic' is set and 'cpoptions' is empty.
Note that a match at the start is preferred, thus when the
pattern is using "*" (any number of matches) it tends to find
zero matches at the start instead of a number of matches
further down in the text.

Parameters:

- {expr} (string|any[])
- {pat} (string)
- {start} (integer?)
- {count} (integer?)

Return:

(integer)

matchadd() E798 E799 E801 E957

matchadd({group}, {pattern} [, {priority} [, {id} [, {dict}]]])
Defines a pattern to be highlighted in the current window (a
"match"). It will be highlighted with {group}. Returns an
identification number (ID), which can be used to delete the
match using matchdelete(). The ID is bound to the window.
Matching is case sensitive and magic, unless case sensitivity
or magicness are explicitly overridden in {pattern}. The
'magic', 'smartcase' and 'ignorecase' options are not used.
The "Conceal" value is special, it causes the match to be
concealed.

The optional {priority} argument assigns a priority to the
match. A match with a high priority will have its
highlighting overrule that of a match with a lower priority.
A priority is specified as an integer (negative numbers are no
exception). If the {priority} argument is not specified, the
default priority is 10. The priority of 'hlsearch' is zero,
hence all matches with a priority greater than zero will
overrule it. Syntax highlighting (see 'syntax') is a separate
mechanism, and regardless of the chosen priority a match will
always overrule syntax highlighting.

The optional {id} argument allows the request for a specific
match ID. If a specified ID is already taken, an error
message will appear and the match will not be added. An ID
is specified as a positive integer (zero excluded). IDs 1, 2
and 3 are reserved for :match, :2match and :3match,
respectively. 3 is reserved for use by the matchparen
plugin.
If the {id} argument is not specified or -1, matchadd()
automatically chooses a free ID, which is at least 1000.

The optional {dict} argument allows for further custom
values. Currently this is used to specify a match specific
conceal character that will be shown for hl-Conceal
highlighted matches. The dict can have the following members:

conceal	Special character to show instead of the match (only for hl-Conceal highlighted matches, see :syn-cchar)
window	Use this window-number or window-ID instead of the current window.

The number of matches is not limited, as it is the case with
the :match commands.

Returns -1 on error.

Example:

```
highlight MyGroup ctermbg=green guibg=green
let m = matchadd("MyGroup", "TODO")
```

Deletion of the pattern:

```
call matchdelete(m)
```

A list of matches defined by matchadd() and :match are available from getmatches(). All matches can be deleted in one operation by clearmatches().

Parameters:

- {group} (integer|string)
- {pattern} (string)
- {priority} (integer?)
- {id} (integer?)
- {dict} (table?)

Return:

(integer)

matchaddpos({group}, {pos} [, {priority} [, {id} [, {dict}]]]) matchaddpos()

Same as matchadd(), but requires a list of positions {pos} instead of a pattern. This command is faster than matchadd() because it does not handle regular expressions and it sets buffer line boundaries to redraw screen. It is supposed to be used when fast match additions and deletions are required, for example to highlight matching parentheses.

E5030 E5031

{pos} is a list of positions. Each position can be one of these:

- A number. This whole line will be highlighted. The first line has number 1.
- A list with one number, e.g., [23]. The whole line with this number will be highlighted.
- A list with two numbers, e.g., [23, 11]. The first number is the line number, the second one is the column number (first column is 1, the value must correspond to the byte index as col() would return). The character at this position will be highlighted.
- A list with three numbers, e.g., [23, 11, 3]. As above, but the third number gives the length of the highlight in bytes.

Entries with zero and negative line numbers are silently ignored, as well as entries with negative column numbers and lengths.

Returns -1 on error.

Example:

```
highlight MyGroup ctermbg=green guibg=green
let m = matchaddpos("MyGroup", [[23, 24], 34])
```

Deletion of the pattern:

```
call matchdelete(m)
```

Matches added by matchaddpos() are returned by getmatches().

Parameters:

- {group} (integer|string)
- {pos} (any[])
- {priority} (integer?)
- {id} (integer?)

- {dict} (table?)

Return:
(integer|table)

matcharg({nr}) matcharg()

Selects the {nr} match item, as set with a :match,
:2match or :3match command.
Return a List with two elements:
The name of the highlight group used
The pattern used.
When {nr} is not 1, 2 or 3 returns an empty List.
When there is no match item set returns ['', ''].
This is useful to save and restore a :match.
Highlighting matches using the :match commands are limited
to three matches. matchadd() does not have this limitation.

Parameters:
- {nr} (integer)

Return:
(string[])

matchbufline({buf}, {pat}, {lnum}, {end}, [, {dict}]) matchbufline()

Returns the List of matches in lines from {lnum} to {end} in
buffer {buf} where {pat} matches.

{lnum} and {end} can either be a line number or the string "$"
to refer to the last line in {buf}.

The {dict} argument supports following items:
submatches include submatch information (/\()

For each match, a Dict with the following items is returned:
byteidx starting byte index of the match
lnum line number where there is a match
text matched string
Note that there can be multiple matches in a single line.

This function works only for loaded buffers. First call
bufload() if needed.

See match-pattern for information about the effect of some
option settings on the pattern.

When {buf} is not a valid buffer, the buffer is not loaded or
{lnum} or {end} is not valid then an error is given and an
empty List is returned.

Examples:

```
" Assuming line 3 in buffer 5 contains "a"
echo matchbufline(5, '\<\k\+\>', 3, 3)
```

[{'lnum': 3, 'byteidx': 0, 'text': 'a'}]

```
" Assuming line 4 in buffer 10 contains "tik tok"
echo matchbufline(10, '\<\k\+\>', 1, 4)
```

[{'lnum': 4, 'byteidx': 0, 'text': 'tik'}, {'lnum': 4, 'byteidx': 4, 'text': 'tok'}]

If {submatch} is present and is v:true, then submatches like
"\1", "\2", etc. are also returned. Example:

```
" Assuming line 2 in buffer 2 contains "acd"
echo matchbufline(2, '\(a\)\?\(b\)\?\(c\)\?\(.*\)', 2, 2
                        \ {'submatches': v:true})
```

[{'lnum': 2, 'byteidx': 0, 'text': 'acd', 'submatches': ['a', '', 'c', 'd', '', '', '', '', '']}]
The "submatches" List always contains 9 items. If a submatch
is not found, then an empty string is returned for that
submatch.

Parameters:
- {buf} (string|integer)
- {pat} (string)
- {lnum} (string|integer)
- {end} (string|integer)
- {dict} (table?)

Return:
(string[])

matchdelete({id} [, {win}]) matchdelete() E802 E803

Deletes a match with ID {id} previously defined by matchadd() or one of the :match commands. Returns 0 if successful, otherwise -1. See example for matchadd(). All matches can be deleted in one operation by clearmatches(). {win} (if given) is a window-number or window-ID.

Parameters:

- {id} (integer)
- {win} (integer?)

Return:

(any)

matchend({expr}, {pat} [, {start} [, {count}]]) matchend()

Same as match(), but return the index of first character after the match. Example:

```
echo matchend("testing", "ing")
```

results in "7".

strspn() strcspn()

Vim doesn't have a strspn() or strcspn() function, but you can do it with matchend():

```
let span = matchend(line, '[a-zA-Z]')
let span = matchend(line, '[^a-zA-Z]')
```

Except that -1 is returned when there are no matches.

The {start}, if given, has the same meaning as for match().

```
echo matchend("testing", "ing", 2)
```

results in "7".

```
echo matchend("testing", "ing", 5)
```

result is "-1".
When {expr} is a List the result is equal to match().

Parameters:

- {expr} (any)
- {pat} (string)
- {start} (integer?)
- {count} (integer?)

Return:

(integer)

matchfuzzy({list}, {str} [, {dict}]) matchfuzzy()

If {list} is a list of strings, then returns a List with all the strings in {list} that fuzzy match {str}. The strings in the returned list are sorted based on the matching score.

The optional {dict} argument always supports the following items:

matchseq	When this item is present return only matches that contain the characters in {str} in the given sequence.
limit	Maximum number of matches in {list} to be returned. Zero means no limit.

If {list} is a list of dictionaries, then the optional {dict} argument supports the following additional items:

key	Key of the item which is fuzzy matched against {str}. The value of this item should be a string.
text_cb	Funcref that will be called for every item in {list} to get the text for fuzzy matching. This should accept a dictionary item as the argument and return the text for that item to use for fuzzy matching.

{str} is treated as a literal string and regular expression matching is NOT supported. Only the first 1024 characters of {str} and of each item in {list} are used for matching; characters beyond that are ignored.

When {str} has multiple words each separated by white space, then the list of strings that have all the words is returned.

If there are no matching strings or there is an error, then an empty list is returned.

When {limit} is given, matchfuzzy() will find up to this number of matches in {list} and return them in sorted order.

Refer to fuzzy-matching for more information about fuzzy matching strings.

Example:

```
echo matchfuzzy(["clay", "crow"], "cay")
```

results in ["clay"].

```
echo getbufinfo()->map({_, v -> v.name})->matchfuzzy("ndl")
```

results in a list of buffer names fuzzy matching "ndl".

```
echo getbufinfo()->matchfuzzy("ndl", {'key' : 'name'})
```

results in a list of buffer information dicts with buffer names fuzzy matching "ndl".

```
echo getbufinfo()->matchfuzzy("spl",
                            \ {'text_cb' : {v -> v.name}})
```

results in a list of buffer information dicts with buffer names fuzzy matching "spl".

```
echo v:oldfiles->matchfuzzy("test")
```

results in a list of file names fuzzy matching "test".

```
let l = readfile("buffer.c")->matchfuzzy("str")
```

results in a list of lines in "buffer.c" fuzzy matching "str".

```
echo ['one two', 'two one']->matchfuzzy('two one')
```

results in ['two one', 'one two'] .

```
echo ['one two', 'two one']->matchfuzzy('two one',
                            \ {'matchseq': 1})
```

results in ['two one'].

Parameters:

- {list} (any[])
- {str} (string)
- {dict} (table?)

Return:

(table)

matchfuzzypos({list}, {str} [, {dict}]) matchfuzzypos()

Same as matchfuzzy(), but returns the list of matched strings, the list of character positions where characters in {str} matches and a list of matching scores. You can use byteidx() to convert a character position to a byte position.

If {str} matches multiple times in a string, then only the positions for the best match is returned.

If there are no matching strings or there is an error, then a list with three empty list items is returned.

Example:

```
echo matchfuzzypos(['testing'], 'tsg')
```

results in [["testing"], [[0, 2, 6]], [99]]

```
echo matchfuzzypos(['clay', 'lacy'], 'la')
```

results in [["lacy", "clay"], [[0, 1], [1, 2]], [153, 133]]

```
echo [{'text': 'hello', 'id' : 10}]
        \ ->matchfuzzypos('ll', {'key' : 'text'})
```

results in [[{"id": 10, "text": "hello"}], [[2, 3]], [127]]

Parameters:

- {list} (any[])

- {str} (string)

- {dict} (table?)

Return:
(table)

matchlist({expr}, {pat} [, {start} [, {count}]]) matchlist()

Same as match(), but return a List. The first item in the list is the matched string, same as what matchstr() would return. Following items are submatches, like "\1", "\2", etc. in :substitute. When an optional submatch didn't match an empty string is used. Example:

```
echo matchlist('acd', '\(a\)\?\(b\)\?\(c\)\?\(.*\)')
```

Results in: ['acd', 'a', '', 'c', 'd', '', '', '', '', ''] When there is no match an empty list is returned.

You can pass in a List, but that is not very useful.

Parameters:
- {expr} (any)

- {pat} (string)

- {start} (integer?)

- {count} (integer?)

Return:
(string[])

matchstr({expr}, {pat} [, {start} [, {count}]]) matchstr()

Same as match(), but return the matched string. Example:

```
echo matchstr("testing", "ing")
```

results in "ing". When there is no match "" is returned. The {start}, if given, has the same meaning as for match().

```
echo matchstr("testing", "ing", 2)
```

results in "ing".

```
echo matchstr("testing", "ing", 5)
```

result is "". When {expr} is a List then the matching item is returned. The type isn't changed, it's not necessarily a String.

Parameters:
- {expr} (any)

- {pat} (string)

- {start} (integer?)

- {count} (integer?)

Return:
(string)

matchstrlist({list}, {pat} [, {dict}]) matchstrlist()

Returns the List of matches in {list} where {pat} matches. {list} is a List of strings. {pat} is matched against each string in {list}.

The {dict} argument supports following items:
```
    submatches  include submatch information (/\()
```

For each match, a Dict with the following items is returned:
```
    byteidx     starting byte index of the match.
    idx         index in {list} of the match.
    text        matched string
    submatches  a List of submatches.  Present only if
                "submatches" is set to v:true in {dict}.
```

See match-pattern for information about the effect of some option settings on the pattern.

Example:

```
echo matchstrlist(['tik tok'], '\<\k\+\>')
```

```
    [{'idx': 0, 'byteidx': 0, 'text': 'tik'}, {'idx': 0, 'byteidx': 4, 'text': 'tok'}]
```

```
echo matchstrlist(['a', 'b'], '\<\k\+\>')
```

```
    [{'idx': 0, 'byteidx': 0, 'text': 'a'}, {'idx': 1, 'byteidx': 0, 'text': 'b'}]
```

If "submatches" is present and is v:true, then submatches like
"\1", "\2", etc. are also returned. Example:

```
echo matchstrlist(['acd'], '\(a\)\?\(b\)\?\(c\)\?\(.*\)',
                          \ #{submatches: v:true})
```

```
    [{'idx': 0, 'byteidx': 0, 'text': 'acd', 'submatches': ['a', '', 'c', 'd', '', '', '', '', '']}]
```

The "submatches" List always contains 9 items. If a submatch
is not found, then an empty string is returned for that
submatch.

Parameters:

- {list} (string[])
- {pat} (string)
- {dict} (table?)

Return:

(string[])

matchstrpos({expr}, {pat} [, {start} [, {count}]]) matchstrpos()

Same as matchstr(), but return the matched string, the start
position and the end position of the match. Example:

```
echo matchstrpos("testing", "ing")
```

results in ["ing", 4, 7].
When there is no match ["", -1, -1] is returned.
The {start}, if given, has the same meaning as for match().

```
echo matchstrpos("testing", "ing", 2)
```

results in ["ing", 4, 7].

```
echo matchstrpos("testing", "ing", 5)
```

result is ["", -1, -1].
When {expr} is a List then the matching item, the index
of first item where {pat} matches, the start position and the
end position of the match are returned.

```
echo matchstrpos([1, '__x'], '\a')
```

result is ["x", 1, 2, 3].
The type isn't changed, it's not necessarily a String.

Parameters:

- {expr} (any)
- {pat} (string)
- {start} (integer?)
- {count} (integer?)

Return:

(table)

max({expr}) max()

Lua: Prefer math.max() with unpack(expr) for lists; dict
values and empty inputs need custom handling.

Return the maximum value of all items in {expr}. Example:

```
echo max([apples, pears, oranges])
```

{expr} can be a List or a Dictionary. For a Dictionary,
it returns the maximum of all values in the Dictionary.
If {expr} is neither a List nor a Dictionary, or one of the
items in {expr} cannot be used as a Number this results in
an error. An empty List or Dictionary results in zero.

Parameters:

- {expr} (any)

Return:
(number)

menu_get({path} [, {modes}]) menu_get()

Returns a List of Dictionaries describing menus (defined by :menu, :amenu, …), including hidden-menus.

{path} matches a menu by name, or all menus if {path} is an empty string. Example:

```
echo menu_get('File','')
echo menu_get('')
```

{modes} is a string of zero or more modes (see maparg() or creating-menus for the list of modes). "a" means "all".

Example:

```
nnoremenu &Test.Test inormal
inoremenu Test.Test insert
vnoremenu Test.Test x
echo menu_get("")
```

returns something like this:

```
[ {
  "hidden": 0,
  "name": "Test",
  "priority": 500,
  "shortcut": 84,
  "submenus": [ {
    "hidden": 0,
    "mappings": {
      i": {
        "enabled": 1,
        "noremap": 1,
        "rhs": "insert",
        "sid": 1,
        "silent": 0
      },
      n": { ... },
      s": { ... },
      v": { ... }
    },
    "name": "Test",
    "priority": 500,
    "shortcut": 0
  } ]
} ]
```

Parameters:
- {path} (string)

- {modes} (string?)

Return:
(any)

menu_info({name} [, {mode}]) menu_info()

Return information about the specified menu {name} in mode {mode}. The menu name should be specified without the shortcut character ('&'). If {name} is "", then the top-level menu names are returned.

{mode} can be one of these strings:

"n"	Normal
"v"	Visual (including Select)
"o"	Operator-pending
"i"	Insert
"c"	Cmd-line
"s"	Select
"x"	Visual
"t"	Terminal-Job
""	Normal, Visual and Operator-pending
"!"	Insert and Cmd-line

When {mode} is omitted, the modes for "" are used.

Returns a Dictionary containing the following items:

accel	menu item accelerator text menu-text
display	display name (name without '&')
enabled	v:true if this menu item is enabled Refer to :menu-enable
icon	name of the icon file (for toolbar) toolbar-icon
iconidx	index of a built-in icon

modes modes for which the menu is defined. In addition to the modes mentioned above, these characters will be used:
" " Normal, Visual and Operator-pending
name menu item name.
noremenu v:true if the {rhs} of the menu item is not remappable else v:false.
priority menu order priority menu-priority
rhs right-hand-side of the menu item. The returned string has special characters translated like in the output of the ":menu" command listing. When the {rhs} of a menu item is empty, then "<Nop>" is returned.
script v:true if script-local remapping of {rhs} is allowed else v:false. See :menu-script.
shortcut shortcut key (character after '&' in the menu name) menu-shortcut
silent v:true if the menu item is created with <silent> argument :menu-silent
submenus List containing the names of all the submenus. Present only if the menu item has submenus.

Returns an empty dictionary if the menu item is not found.

Examples:

```
echo menu_info('Edit.Cut')
echo menu_info('File.Save', 'n')

" Display the entire menu hierarchy in a buffer
func ShowMenu(name, pfx)
  let m = menu_info(a:name)
  call append(line('$'), a:pfx .. m.display)
  for child in m->get('submenus', [])
    call ShowMenu(a:name .. '.' .. escape(child, '.'),
                               \ a:pfx .. '    ')
  endfor
endfunc
new
for topmenu in menu_info('').submenus
  call ShowMenu(topmenu, '')
endfor
```

Parameters:
- {name} (string)

- {mode} (string?)

Return:
(any)

min({expr}) min()

Lua: Prefer math.min() with unpack(expr) for lists; dict values and empty inputs need custom handling.

Return the minimum value of all items in {expr}. Example:

```
echo min([apples, pears, oranges])
```

{expr} can be a List or a Dictionary. For a Dictionary, it returns the minimum of all values in the Dictionary. If {expr} is neither a List nor a Dictionary, or one of the items in {expr} cannot be used as a Number this results in an error. An empty List or Dictionary results in zero.

Parameters:
- {expr} (any)

Return:
(number)

mkdir({name} [, {flags} [, {prot}]]) mkdir() E739

Lua: Prefer vim.fs.mkdir(); "D", "R", and return semantics differ.

Create directory {name}.

When {flags} is present it must be a string. An empty string has no effect.

{flags} can contain these character flags:
"p" intermediate directories will be created as necessary
"D" {name} will be deleted at the end of the current function, but not recursively :defer
"R" {name} will be deleted recursively at the end of the current function :defer

Note that when {name} has more than one part and "p" is used some directories may already exist. Only the first one that

is created and what it contains is scheduled to be deleted.
E.g. when using:

```
call mkdir('subdir/tmp/autoload', 'pR')
```

and "subdir" already exists then "subdir/tmp" will be
scheduled for deletion, like with:

```
defer delete('subdir/tmp', 'rf')
```

If {prot} is given it is used to set the protection bits of
the new directory. The default is 0o755 (rwxr-xr-x: r/w for
the user, readable for others). Use 0o700 to make it
unreadable for others. This is used for the newly created
directories. **Note:** umask is applied to {prot} (on Unix).
Example:

```
call mkdir($HOME .. "/tmp/foo/bar", "p", 0o700)
```

This function is not available in the sandbox.

If you try to create an existing directory with {flags} set to
"p" mkdir() will silently exit.

The function result is a Number, which is TRUE if the call was
successful or FALSE if the directory creation failed or partly
failed.

Parameters:

- {name} (string)
- {flags} (string?)
- {prot} (string?)

Return:

(integer)

mode([{expr}]) mode()

Lua: Prefer nvim_get_mode(); use the .mode field. It
always returns the full mode string, unlike mode() without a
non-zero {expr}.

Return a string that indicates the current mode.
If {expr} is supplied and it evaluates to a non-zero Number or
a non-empty String (non-zero-arg), then the full mode is
returned, otherwise only the first letter is returned.
Also see state().

```
n        Normal
no       Operator-pending
nov      Operator-pending (forced charwise o_v)
noV      Operator-pending (forced linewise o_V)
noCTRL-V Operator-pending (forced blockwise o_CTRL-V)
             CTRL-V is one character
niI      Normal using i_CTRL-O in Insert-mode
niR      Normal using i_CTRL-O in Replace-mode
niV      Normal using i_CTRL-O in Virtual-Replace-mode
nt       Normal in terminal-emulator (insert goes to
             Terminal mode)
ntT      Normal using t_CTRL-\_CTRL-O in Terminal-mode
v        Visual by character
vs       Visual by character using v_CTRL-O in Select mode
V        Visual by line
Vs       Visual by line using v_CTRL-O in Select mode
CTRL-V   Visual blockwise
CTRL-Vs  Visual blockwise using v_CTRL-O in Select mode
s        Select by character
S        Select by line
CTRL-S   Select blockwise
i        Insert
ic       Insert mode completion compl-generic
ix       Insert mode i_CTRL-X completion
R        Replace R
Rc       Replace mode completion compl-generic
Rx       Replace mode i_CTRL-X completion
Rv       Virtual Replace gR
Rvc      Virtual Replace mode completion compl-generic
Rvx      Virtual Replace mode i_CTRL-X completion
c        Command-line editing
cr       Command-line editing overstrike mode c_<Insert>
cv       Non-interactive Ex mode -es
r        Hit-enter prompt
rm       The -- more -- prompt
r?       A :confirm query of some sort
!        Shell or external command is executing
t        Terminal mode: keys go to the job
```

This is useful in the 'statusline' option or RPC calls. In
most other places it always returns "c" or "n".
Note that in the future more modes and more specific modes may
be added. It's better not to compare the whole string but
only the leading character(s).
Also see visualmode().

Parameters:
- {expr} (any?)

Return:
(any)

msgpackdump({list} [, {type}]) msgpackdump()

Lua: Prefer vim.mpack.encode(); list wrapping, return shape,
and special-dict semantics differ.

Convert a list of Vimscript objects to msgpack. Returned value is a
readfile()-style list. When {type} contains "B", a Blob is
returned instead. Example:

```
call writefile(msgpackdump([{}]), 'fname.mpack', 'b')
```

or, using a Blob:

```
call writefile(msgpackdump([{}], 'B'), 'fname.mpack')
```

This will write the single 0x80 byte to a fname.mpack file
(dictionary with zero items is represented by 0x80 byte in
messagepack).

Limitations: E5004 E5005

1. Funcrefs cannot be dumped.

2. Containers that reference themselves cannot be dumped.

3. Dictionary keys are always dumped as STR strings.

4. Other strings and Blobs are always dumped as BIN strings.

5. Points 3. and 4. do not apply to msgpack-special-dicts.

Parameters:
- {list} (any)

- {type} (any?)

Return:
(any)

msgpackparse({data}) msgpackparse()

Lua: Prefer vim.mpack.decode(); input and special-dict
semantics differ.

Convert a readfile()-style list or a Blob to a list of
Vimscript objects.
Example:

```
let fname = expand('~/.config/nvim/shada/main.shada')
let mpack = readfile(fname, 'b')
let shada_objects = msgpackparse(mpack)
```

This will read ~/.config/nvim/shada/main.shada file to
shada_objects list.

Limitations:

1. Mapping ordering is not preserved unless messagepack
   mapping is dumped using generic mapping
   (msgpack-special-map).
2. Since the parser aims to preserve all data untouched
   (except for 1.) some strings are parsed to
   msgpack-special-dict format which is not convenient to
   use.

msgpack-special-dict

Some messagepack strings may be parsed to special
dictionaries. Special dictionaries are dictionaries which

3. Contain exactly two keys: _TYPE and _VAL.

4. _TYPE key is one of the types found in v:msgpack_types

variable.
5. Value for _VAL has the following format (Key column

contains name of the key from v:msgpack_types):

Key	Value
nil	Zero, ignored when dumping. Not returned by msgpackparse() since v:null was introduced.
boolean	One or zero. When dumping it is only checked that value is a Number. Not returned by msgpackparse() since v:true and v:false were introduced.

integer	List with four numbers: sign (-1 or 1), highest two bits, number with bits from 62nd to 31st, lowest 31 bits. I.e. to get actual number one will need to use code like
	`_VAL[0] * ((_VAL[1] << 62)`
	`& (_VAL[2] << 31)`
	`& _VAL[3])`

Special dictionary with this type will appear in
msgpackparse() output under one of the following
circumstances:
1. Number is 32-bit and value is either above

INT32_MAX or below INT32_MIN.
2. Number is 64-bit and value is above INT64_MAX. It

cannot possibly be below INT64_MIN because msgpack
C parser does not support such values.

float Float. This value cannot possibly appear in
msgpackparse() output.

string String, or Blob if binary string contains zero
byte. This value cannot appear in msgpackparse()
output since blobs were introduced.

array List. This value cannot appear in msgpackparse()
output.

msgpack-special-map

map List of Lists with two items (key and value) each.
This value will appear in msgpackparse() output if
parsed mapping contains one of the following keys:
3. Any key that is not a string (including keys which

are binary strings).
4. String with NUL byte inside.

5. Duplicate key.

ext List with two values: first is a signed integer
representing extension type. Second is
readfile()-style list of strings.

Parameters:
- {data} (any)

Return:
(any)

nextnonblank({lnum}) nextnonblank()

Return the line number of the first line at or below {lnum}
that is not blank. Example:

```
if getline(nextnonblank(1)) =~ "Java" | endif
```

When {lnum} is invalid or there is no non-blank line at or
below it, zero is returned.
{lnum} is used like with getline().
See also prevnonblank().

Parameters:
- {lnum} (integer|string)

Return:
(integer)

nr2char({expr} [, {utf8}]) nr2char()

Lua: Prefer string.char(): only works with ASCII.

Gets a UTF-8 string for a single codepoint {expr}.
Examples:

```
echo nr2char(64)                " returns '@'
echo nr2char(32)                " returns ' '
echo nr2char(300)               " returns I with bow character
```

UTF-8 encoding is always used, {utf8} option has no effect,
and exists only for backwards-compatibility.
Note that a NUL character in the file is specified with
nr2char(10), because NULs are represented with newline
characters. nr2char(0) is a real NUL and terminates the
string, thus results in an empty string.

Attributes:
api-fast

Parameters:
- {expr} (integer)

- {utf8} (boolean?)

Return:
(string)

nvim_...({...}) nvim_...() E5555 eval-api

Lua: Prefer vim.api.

Call nvim api functions. The type checking of arguments will
be stricter than for most other builtins. For instance,
if Integer is expected, a Number must be passed in, a
String will not be autoconverted.
Buffer numbers, as returned by bufnr() could be used as
first argument to nvim_buf_... functions. All functions
expecting an object (buffer, window or tabpage) can
also take the numerical value 0 to indicate the current
(focused) object.

Parameters:
- {...} (any)

Return:
(any)

or({expr}, {expr}) or()

Lua: Prefer bit.bor().

Bitwise OR on the two arguments. The arguments are converted
to a number. A List, Dict or Float argument causes an error.
Also see and() and xor().
Example:

```
let bits = or(bits, 0x80)
```

Rationale: The reason this is a function and not using the "|"
character like many languages, is that Vi has always used "|"
to separate commands. In many places it would not be clear if
"|" is an operator or a command separator.

Parameters:
- {expr} (number)

- {expr1} (number)

Return:
(any)

pathshorten({path} [, {len}]) pathshorten()

Shorten directory names in the path {path} and return the
result. The tail, the file name, is kept as-is. The other
components in the path are reduced to {len} letters in length.
If {len} is omitted or smaller than 1 then 1 is used (single
letters). Leading '~' and '.' characters are kept. Examples:

```
echo pathshorten('~/.config/nvim/autoload/file1.vim')
```

~/.c/n/a/file1.vim

```
echo pathshorten('~/.config/nvim/autoload/file2.vim', 2)
```

~/.co/nv/au/file2.vim
It doesn't matter if the path exists or not.
Returns an empty string on error.

Parameters:

- {path} (string)

- {len} (integer?)

Return:
(string)

perleval({expr}) perleval()

Evaluate perl expression {expr} and return its result
converted to Vim data structures.
Numbers and strings are returned as they are (strings are
copied though).
Lists are represented as Vim List type.
Dictionaries are represented as Vim Dictionary type,
non-string keys result in error.

Note: If you want an array or hash, {expr} must return a
reference to it.
Example:

```
echo perleval('[1 .. 4]')
```

[1, 2, 3, 4]

Parameters:
- {expr} (any)

Return:
(any)

pow({x}, {y}) pow()

Lua: Prefer math.pow().

Return the power of {x} to the exponent {y} as a Float.
{x} and {y} must evaluate to a Float or a Number.
Returns 0.0 if {x} or {y} is not a Float or a Number.
Examples:

```
echo pow(3, 3)
```

27.0

```
echo pow(2, 16)
```

65536.0

```
echo pow(32, 0.20)
```

2.0

Parameters:
- {x} (number)

- {y} (number)

Return:
(number)

preinserted() preinserted()

Returns non-zero if text has been inserted after the cursor
because "preinsert" is present in 'completeopt', or because
"longest" is present in 'completeopt' while 'autocomplete'
is active. Otherwise returns zero.

Return:
(number)

prevnonblank({lnum}) prevnonblank()

Return the line number of the first line at or above {lnum}
that is not blank. Example:

```
let ind = indent(prevnonblank(v:lnum - 1))
```

When {lnum} is invalid or there is no non-blank line at or
above it, zero is returned.
{lnum} is used like with getline().
Also see nextnonblank().

Parameters:
- {lnum} (integer|string)

Return:
(integer)

printf({fmt}, {expr1} ...) printf()

Lua: Prefer string.format().

Return a String with {fmt}, where "%" items are replaced by the formatted form of their respective arguments. Example:

```
echo printf("%4d: E%d %.30s", lnum, errno, msg)
```

May result in:

```
"  99: E42 asdfasdfasdfasdfasdfasdfasdfas"
```

When used as a method the base is passed as the second argument:

```
Compute()->printf("result: %d")
```

You can use call() to pass the items as a list.

Often used items are:

```
  %s    string
  %6S   string right-aligned in 6 display cells
  %6s   string right-aligned in 6 bytes
  %.9s  string truncated to 9 bytes
  %c    single byte
  %d    decimal number
  %5d   decimal number padded with spaces to 5 characters
  %b    binary number
  %08b  binary number padded with zeros to at least 8 characters
  %B    binary number using upper case letters
  %x    hex number
  %04x  hex number padded with zeros to at least 4 characters
  %X    hex number using upper case letters
  %o    octal number
  %f    floating point number as 12.23, inf, -inf or nan
  %F    floating point number as 12.23, INF, -INF or NAN
  %e    floating point number as 1.23e3, inf, -inf or nan
  %E    floating point number as 1.23E3, INF, -INF or NAN
  %g    floating point number, as %f or %e depending on value
  %G    floating point number, as %F or %E depending on value
  %%    the % character itself
  %p    representation of the pointer to the container
```

Conversion specifications start with '%' and end with the conversion type. All other characters are copied unchanged to the result.

The "%" starts a conversion specification. The following arguments appear in sequence:

```
        % [pos-argument] [flags] [field-width] [.precision] type
```

pos-argument
: At most one positional argument specifier. These take the form {n$}, where n is >= 1.

flags
: Zero or more of the following flags:

    #
    : The value should be converted to an "alternate form". For c, d, and s conversions, this option has no effect. For o conversions, the precision of the number is increased to force the first character of the output string to a zero (except if a zero value is printed with an explicit precision of zero).
    For x and X conversions, a non-zero result has the string "0x" (or "0X" for X conversions) prepended to it.

    0 (zero)
    : Zero padding. For all conversions the converted value is padded on the left with zeros rather than blanks. If a precision is given with a numeric conversion (d, o, x, and X), the 0 flag is ignored.

    -
    : A negative field width flag; the converted value is to be left adjusted on the field boundary. The converted value is padded on the right with blanks, rather than on the left with blanks or zeros. A - overrides a 0 if both are given.

    ' ' (space)
    : A blank should be left before a positive number produced by a signed conversion (d).

    +
    : A sign must always be placed before a number produced by a signed conversion. A + overrides a space if both are used.

field-width
: An optional decimal digit string specifying a minimum field width. If the converted value has fewer bytes than the field width, it will be padded with spaces on the left (or right, if the left-adjustment flag has been given) to fill out the field width. For the S conversion the count is in cells.

.precision
        An optional precision, in the form of a period '.'
        followed by an optional digit string. If the digit
        string is omitted, the precision is taken as zero.
        This gives the minimum number of digits to appear for
        d, o, x, and X conversions, the maximum number of
        bytes to be printed from a string for s conversions,
        or the maximum number of cells to be printed from a
        string for S conversions.
        For floating point it is the number of digits after
        the decimal point.

type
        A character that specifies the type of conversion to
        be applied, see below.

A field width or precision, or both, may be indicated by an
asterisk "*" instead of a digit string. In this case, a
Number argument supplies the field width or precision. A
negative field width is treated as a left adjustment flag
followed by a positive field width; a negative precision is
treated as though it were missing. Example:

```
echo printf("%d: %.*s", nr, width, line)
```

This limits the length of the text used from "line" to
"width" bytes.

If the argument to be formatted is specified using a
positional argument specifier, and a '*' is used to indicate
that a number argument is to be used to specify the width or
precision, the argument(s) to be used must also be specified
using a {n$} positional argument specifier. See printf-$.

The conversion specifiers and their meanings are:

printf-d printf-b printf-B printf-o printf-x printf-X

dbBoxX The Number argument is converted to signed decimal (d),
        unsigned binary (b and B), unsigned octal (o), or
        unsigned hexadecimal (x and X) notation. The letters
        "abcdef" are used for x conversions; the letters
        "ABCDEF" are used for X conversions. The precision, if
        any, gives the minimum number of digits that must
        appear; if the converted value requires fewer digits, it
        is padded on the left with zeros. In no case does a
        non-existent or small field width cause truncation of a
        numeric field; if the result of a conversion is wider
        than the field width, the field is expanded to contain
        the conversion result.
        The 'h' modifier indicates the argument is 16 bits.
        The 'l' modifier indicates the argument is a long
        integer. The size will be 32 bits or 64 bits
        depending on your platform.
        The "ll" modifier indicates the argument is 64 bits.
        The b and B conversion specifiers never take a width
        modifier and always assume their argument is a 64 bit
        integer.
        Generally, these modifiers are not useful. They are
        ignored when type is known from the argument.

i   alias for d
D   alias for ld
U   alias for lu
O   alias for lo

printf-c

c   The Number argument is converted to a byte, and the
        resulting character is written.

printf-s

s   The text of the String argument is used. If a
        precision is specified, no more bytes than the number
        specified are used.
        If the argument is not a String type, it is
        automatically converted to text with the same format
        as ":echo".

printf-S

S   The text of the String argument is used. If a
        precision is specified, no more display cells than the
        number specified are used.

printf-f E807

f F   The Float argument is converted into a string of the
        form 123.456. The precision specifies the number of
        digits after the decimal point. When the precision is
        zero the decimal point is omitted. When the precision
        is not specified 6 is used. A really big number
        (out of range or dividing by zero) results in "inf"
         or "-inf" with %f (INF or -INF with %F).
         "0.0 / 0.0" results in "nan" with %f (NAN with %F).
        Example:

```
echo printf("%.2f", 12.115)
```

```
        12.12
```

Note that roundoff depends on the system libraries.
Use round() when in doubt.

printf-e printf-E

e E The Float argument is converted into a string of the form 1.234e+03 or 1.234E+03 when using 'E'. The precision specifies the number of digits after the decimal point, like with 'f'.

printf-g printf-G

g G The Float argument is converted like with 'f' if the value is between 0.001 (inclusive) and 10000000.0 (exclusive). Otherwise 'e' is used for 'g' and 'E' for 'G'. When no precision is specified superfluous zeroes and '+' signs are removed, except for the zero immediately after the decimal point. Thus 10000000.0 results in 1.0e7.

printf-%

% A '%' is written. No argument is converted. The complete conversion specification is "%%".

When a Number argument is expected a String argument is also accepted and automatically converted.
When a Float or String argument is expected a Number argument is also accepted and automatically converted.
Any other argument type results in an error message.

E766 E767

The number of {exprN} arguments must exactly match the number of "%" items. If there are not sufficient or too many arguments an error is given. Up to 18 arguments can be used.

printf-$

In certain languages, error and informative messages are more readable when the order of words is different from the corresponding message in English. To accommodate translations having a different word order, positional arguments may be used to indicate this. For instance:

```
#, c-format
msgid "%s returning %s"
msgstr "waarde %2$s komt terug van %1$s"
```

In this example, the sentence has its 2 string arguments reversed in the output.

```
echo printf(
    "In The Netherlands, vim's creator's name is: %1$s %2$s",
    "Bram", "Moolenaar")
```

```
    In The Netherlands, vim's creator's name is: Bram Moolenaar
```

```
echo printf(
    "In Belgium, vim's creator's name is: %2$s %1$s",
    "Bram", "Moolenaar")
```

```
    In Belgium, vim's creator's name is: Moolenaar Bram
```

Width (and precision) can be specified using the '*' specifier. In this case, you must specify the field width position in the argument list.

```
echo printf("%1$*2$.*3$d", 1, 2, 3)
```

```
    001
```

```
echo printf("%2$*3$.*1$d", 1, 2, 3)
```

```
      2
```

```
echo printf("%3$*1$.*2$d", 1, 2, 3)
```

```
    03
```

```
echo printf("%1$*2$.*3$g", 1.4142, 2, 3)
```

```
    1.414
```

You can mix specifying the width and/or precision directly and via positional arguments:

```
echo printf("%1$4.*2$f", 1.4142135, 6)
```

1.414214

```
echo printf("%1$*2$.4f", 1.4142135, 6)
```

1.4142

```
echo printf("%1$*2$.*3$f", 1.4142135, 6, 2)
```

1.41

You will get an overflow error E1510, when the field-width
or precision will result in a string longer than 1 MiB
(1024*1024 = 1048576) chars.

E1500

You cannot mix positional and non-positional arguments:

```
echo printf("%s%1$s", "One", "Two")
" E1500: Cannot mix positional and non-positional arguments:
" %s%1$s
```

E1501

You cannot skip a positional argument in a format string:

```
echo printf("%3$s%1$s", "One", "Two", "Three")
" E1501: format argument 2 unused in $-style format:
" %3$s%1$s
```

E1502

You can re-use a [field-width] (or [precision]) argument:

```
echo printf("%1$d at width %2$d is: %1$0*2$d", 1, 2)
" 1 at width 2 is: 01
```

However, you can't use it as a different type:

```
echo printf("%1$d at width %2$ld is: %1$0*2$d", 1, 2)
" E1502: Positional argument 2 used as field width reused as
" different type: long int/int
```

E1503

When a positional argument is used, but not the correct number
or arguments is given, an error is raised:

```
echo printf("%1$d at width %2$d is: %1$0*2$.*3$d", 1, 2)
" E1503: Positional argument 3 out of bounds: %1$d at width
" %2$d is: %1$0*2$.*3$d
```

Only the first error is reported:

```
echo printf("%1$0*2$.*3$d %4$d", 1, 2)
" E1503: Positional argument 3 out of bounds: %1$0*2$.*3$d
" %4$d
```

E1504

A positional argument can be used more than once:

```
echo printf("%1$s %2$s %1$s", "One", "Two")
" One Two One
```

However, you can't use a different type the second time:

```
echo printf("%1$s %2$s %1$d", "One", "Two")
" E1504: Positional argument 1 type used inconsistently:
" int/string
```

E1505

Various other errors that lead to a format string being
wrongly formatted lead to:

```
echo printf("%1$d at width %2$d is: %01$*2$.3$d", 1, 2)
" E1505: Invalid format specifier: %1$d at width %2$d is:
" %01$*2$.3$d
```

E1507

This internal error indicates that the logic to parse a
positional format argument ran into a problem that couldn't be
otherwise reported. Please file a bug against Vim if you run
into this, copying the exact format string and parameters that
were used.

Parameters:

- {fmt} (string)

- {expr1} (any?)

Return:
(string)

prompt_appendbuf({buf}, {text}) prompt_appendbuf()

Appends text to prompt buffer before current prompt. When {text} is a List: Append each item of the List as a text line above prompt-line in the buffer. Any type of item is accepted and converted to a String. Returns 1 for failure ({buf} not a prmopt buffer), 0 for success. When {text} is an empty list zero is returned.

Example:

```
func TextEntered(text)
  call prompt_appendbuf(bufnr(''), split('Entered: "' . a:text . '"', '\n'))
endfunc

set buftype=prompt
call prompt_setcallback(bufnr(''), function("TextEntered"))
eval bufnr("")->prompt_setprompt("cmd: ")
startinsert
```

Parameters:
- {buf} (integer|string)

- {text} (string|string[])

Return:
(0|1)

prompt_getinput({buf}) prompt_getinput()

Gets the current user-input in prompt-buffer {buf} without invoking prompt_callback. {buf} can be a buffer name or number.

If the buffer doesn't exist or isn't a prompt buffer, an empty string is returned.

Parameters:
- {buf} (integer|string)

Return:
(any)

prompt_getprompt({buf}) prompt_getprompt()

Returns the effective prompt text for buffer {buf}. {buf} can be a buffer name or number. See prompt-buffer.

If the buffer doesn't exist or isn't a prompt buffer, an empty string is returned.

Parameters:
- {buf} (integer|string)

Return:
(any)

prompt_setcallback({buf}, {expr}) prompt_setcallback()

Set prompt callback for buffer {buf} to {expr}. When {expr} is an empty string the callback is removed. This has only effect if {buf} has 'buftype' set to "prompt".

The callback is invoked when pressing Enter. The current buffer will always be the prompt buffer. A new line for a prompt is added before invoking the callback, thus the prompt for which the callback was invoked will be in the last but one line.
If the callback wants to add text to the buffer, it must insert it above the last line, since that is where the current prompt is. This can also be done asynchronously.
The callback is invoked with one argument, which is the text that was entered at the prompt. This can be an empty string if the user only typed Enter.
Example:

```
func s:TextEntered(text)
  if a:text == 'exit' || a:text == 'quit'
    stopinsert
    " Reset 'modified' to allow the buffer to be closed.
    " We assume there is nothing useful to be saved.
    set nomodified
    close
  else
    " Do something useful with "a:text".  In this example
    " we just repeat it.
    call append(line('$') - 1, 'Entered: "' .. a:text .. '"')
  endif
endfunc
call prompt_setcallback(bufnr(), function('s:TextEntered'))
```

Parameters:
- {buf} (integer|string)

- {expr} (string|function)

Return:
(any)

prompt_setinterrupt({buf}, {expr}) prompt_setinterrupt()

Set a callback for buffer {buf} to {expr}. When {expr} is an empty string the callback is removed. This has only effect if {buf} has 'buftype' set to "prompt".

This callback will be invoked when pressing CTRL-C in Insert mode. Without setting a callback Vim will exit Insert mode, as in any buffer.

Parameters:
- {buf} (integer|string)

- {expr} (string|function)

Return:
(any)

prompt_setprompt({buf}, {text}) prompt_setprompt()

Set prompt for buffer {buf} to {text}. You most likely want {text} to end in a space.
The result is only visible if {buf} has 'buftype' set to "prompt". Example:

```
call prompt_setprompt(bufnr(''), 'command: ')
```

Parameters:
- {buf} (integer|string)

- {text} (string)

Return:
(any)

pum_getpos() pum_getpos()

If the popup menu (see ins-completion-menu) is not visible, returns an empty Dictionary, otherwise, returns a Dictionary with the following keys:

height	nr of items visible
width	screen cells
row	top screen row (0 first row)
col	leftmost screen column (0 first col)
size	total nr of items
scrollbar	TRUE if scrollbar is visible

The values are the same as in v:event during CompleteChanged.

Return:
(any)

pumvisible() pumvisible()

Returns non-zero when the popup menu is visible, zero otherwise. See ins-completion-menu.
This can be used to avoid some things that would remove the popup menu.

Return:
(any)

py3eval({expr}) py3eval()

Evaluate Python expression {expr} and return its result

converted to Vim data structures.
Numbers and strings are returned as they are (strings are
copied though, Unicode strings are additionally converted to
UTF-8).
Lists are represented as Vim List type.
Dictionaries are represented as Vim Dictionary type with
keys converted to strings.

Parameters:
- {expr} (any)

Return:
(any)

pyeval({expr}) pyeval() E858 E859

Evaluate Python expression {expr} and return its result
converted to Vim data structures.
Numbers and strings are returned as they are (strings are
copied though).
Lists are represented as Vim List type.
Dictionaries are represented as Vim Dictionary type,
non-string keys result in error.

Parameters:
- {expr} (any)

Return:
(any)

pyxeval({expr}) pyxeval()

Evaluate Python expression {expr} and return its result
converted to Vim data structures.
Uses Python 2 or 3, see python x and 'pyxversion'.
See also: pyeval(), py3eval()

Parameters:
- {expr} (any)

Return:
(any)

rand([{expr}]) rand()

Lua: Prefer math.random().

Return a pseudo-random Number generated with an xoshiro128**
algorithm using seed {expr}. The returned number is 32 bits,
also on 64 bits systems, for consistency.
{expr} can be initialized by srand() and will be updated by
rand(). If {expr} is omitted, an internal seed value is used
and updated.
Returns -1 if {expr} is invalid.

Examples:

```
echo rand()
let seed = srand()
echo rand(seed)
echo rand(seed) % 16  " random number 0 - 15
```

Parameters:
- {expr} (number?)

Return:
(any)

range({expr} [, {max} [, {stride}]]) range() E726 E727

Returns a List with Numbers:
- If only {expr} is specified: [0, 1, ..., {expr} - 1]
- If {max} is specified: [{expr}, {expr} + 1, ..., {max}]
- If {stride} is specified: [{expr}, {expr} + {stride}, ...,

  {max}] (increasing {expr} with {stride} each time, not
  producing a value past {max}).
When the maximum is one before the start the result is an
empty list. When the maximum is more than one before the
start this is an error.
Examples:

```
echo range(4)           " [0, 1, 2, 3]
echo range(2, 4)        " [2, 3, 4]
echo range(2, 9, 3)     " [2, 5, 8]
echo range(2, -2, -1)   " [2, 1, 0, -1, -2]
echo range(0)           " []
echo range(2, 0)        " error!
```

Parameters:

- {expr} (any)
- {max} (integer?)
- {stride} (integer?)

Return:

(any)

readblob({fname} [, {offset} [, {size}]]) readblob()

Lua: Prefer io.open() with :read("*a") in binary mode for whole-file reads; offset, size, and Blob return differ.

Read file {fname} in binary mode and return a Blob.
If {offset} is specified, read the file from the specified offset. If it is a negative value, it is used as an offset from the end of the file. E.g., to read the last 12 bytes:

```
echo readblob('file.bin', -12)
```

If {size} is specified, only the specified size will be read. E.g. to read the first 100 bytes of a file:

```
echo readblob('file.bin', 0, 100)
```

If {size} is -1 or omitted, the whole data starting from {offset} will be read.
This can be also used to read the data from a character device on Unix when {size} is explicitly set. Only if the device supports seeking {offset} can be used. Otherwise it should be zero. E.g. to read 10 bytes from a serial console:

```
echo readblob('/dev/ttyS0', 0, 10)
```

When the file can't be opened an error message is given and the result is an empty Blob.
When the offset is beyond the end of the file the result is an empty blob.
When trying to read more bytes than are available the result is truncated.
Also see readfile() and writefile().

Parameters:

- {fname} (string)
- {offset} (integer?)
- {size} (integer?)

Return:

(any)

readdir({directory} [, {expr}]) readdir()

Lua: Prefer vim.fs.dir() as an iterator, then collect and filter results as needed.

Return a list with file and directory names in {directory}.
You can also use glob() if you don't need to do complicated things, such as limiting the number of matches.

When {expr} is omitted all entries are included.
When {expr} is given, it is evaluated to check what to do:
- If {expr} results in -1 then no further entries will be handled.
- If {expr} results in 0 then this entry will not be added to the list.
- If {expr} results in 1 then this entry will be added to the list.

Each time {expr} is evaluated v:val is set to the entry name.
When {expr} is a function the name is passed as the argument.
For example, to get a list of files ending in ".txt":

```
echo readdir(dirname, {n -> n =~ '\.txt$'})
```

To skip hidden and backup files:

```
echo readdir(dirname, {n -> n !~ '^\.\|\~$'})
```

If you want to get a directory tree:

```
function! s:tree(dir)
    return {a:dir : map(readdir(a:dir),
    \ {_, x -> isdirectory(x) ?
    \          {x : s:tree(a:dir .. '/' .. x)} : x})}
endfunction
echo s:tree(".")
```

Returns an empty List on error.

Parameters:

- {directory} (string)
- {expr} (integer|string|fun(name: string): integer?)

Return:

(any)

readfile({fname} [, {type} [, {max}]]) readfile()

Lua: Prefer io.open() with :read("*a"), then split lines as needed; {type}, {max}, and Blob return differ.

Read file {fname} and return a List, each line of the file as an item. Lines are broken at NL characters. Macintosh files separated with CR will result in a single long line (unless a NL appears somewhere).
All NUL characters are replaced with a NL character.
When {type} contains "b" binary mode is used:

- When the last line ends in a NL an extra empty list item is added.
- No CR characters are removed.

Otherwise:

- CR characters that appear before a NL are removed.
- Whether the last line ends in a NL or not does not matter.
- Any UTF-8 byte order mark is removed from the text.

When {max} is given this specifies the maximum number of lines to be read. Useful if you only want to check the first ten lines of a file:

```
for line in readfile(fname, '', 10)
  if line =~ 'Date' | echo line | endif
endfor
```

When {max} is negative -{max} lines from the end of the file are returned, or as many as there are.
When {max} is zero the result is an empty list.
Note that without {max} the whole file is read into memory.
Also note that there is no recognition of encoding. Read a file into a buffer if you need to.
Deprecated (use readblob() instead): When {type} contains "B" a Blob is returned with the binary data of the file unmodified.
When the file can't be opened an error message is given and the result is an empty list.
Also see writefile().

Parameters:

- {fname} (string)
- {type} (string?)
- {max} (integer?)

Return:

(string[])

reduce({object}, {func} [, {initial}]) reduce() E998

Lua: Prefer Iter:fold().

{func} is called for every item in {object}, which can be a String, List or a Blob. {func} is called with two

arguments: the result so far and current item. After
processing all items the result is returned. E1132

{initial} is the initial result. When omitted, the first item
in {object} is used and {func} is first called for the second
item. If {initial} is not given and {object} is empty no
result can be computed, an E998 error is given.

Examples:

```
echo reduce([1, 3, 5], { acc, val -> acc + val })
echo reduce(['x', 'y'], { acc, val -> acc .. val }, 'a')
echo reduce(0z1122, { acc, val -> 2 * acc + val })
echo reduce('xyz', { acc, val -> acc .. ',' .. val })
```

Parameters:
- {object} (any)
- {func} (fun(accumulator: T, current: any): any)
- {initial} (any?)

Return:
(T)

reg_executing() reg_executing()

Returns the single letter name of the register being executed.
Returns an empty string when no register is being executed.
See @.

Return:
(any)

reg_recorded() reg_recorded()

Returns the single letter name of the last recorded register.
Returns an empty string when nothing was recorded yet.
See q and Q.

Return:
(any)

reg_recording() reg_recording()

Returns the single letter name of the register being recorded.
Returns an empty string when not recording. See q.

Return:
(any)

reltime() reltime()

reltime({start})
reltime({start}, {end})
Lua: Prefer uv.hrtime().

Return an item that represents a time value. The item is a
list with items that depend on the system.
The item can be passed to reltimestr() to convert it to a
string or reltimefloat() to convert to a Float.

Without an argument it returns the current "relative time", an
implementation-defined value meaningful only when used as an
argument to reltime(), reltimestr() and reltimefloat().

With one argument it returns the time passed since the time
specified in the argument.
With two arguments it returns the time passed between {start}
and {end}.

The {start} and {end} arguments must be values returned by
reltime(). Returns zero on error.

Note: localtime() returns the current (non-relative) time.

Attributes:
api-fast

Parameters:
- {start} (any?)
- {end} (any?)

Return:
(any)

reltimefloat({time}) reltimefloat()

Lua: Prefer uv.hrtime() with (finish - start) / 1e9 for
elapsed seconds.

Return a Float that represents the time value of {time}.
Unit of time is seconds.

Example:
```
	let start = reltime()
	call MyFunction()
	let seconds = reltimefloat(reltime(start))
```
See the note of reltimestr() about overhead.
Also see profiling.
If there is an error an empty string is returned

Attributes:
api-fast

Parameters:
- {time} (any)

Return:
(any)

reltimestr({time}) reltimestr()

Return a String that represents the time value of {time}.
This is the number of seconds, a dot and the number of
microseconds. Example:

```
let start = reltime()
call MyFunction()
echo reltimestr(reltime(start))
```

Note that overhead for the commands will be added to the time.
Leading spaces are used to make the string align nicely. You
can use split() to remove it.

```
echo split(reltimestr(reltime(start)))[0]
```

Also see profiling.
If there is an error an empty string is returned

Attributes:
api-fast

Parameters:
- {time} (any)

Return:
(any)

remove({list}, {idx}) remove()

Lua: Prefer table.remove().

remove({list}, {idx}, {end})
Without {end}: Remove the item at {idx} from List {list} and
return the item.
With {end}: Remove items from {idx} to {end} (inclusive) and
return a List with these items. When {idx} points to the same
item as {end} a list with one item is returned. When {end}
points to an item before {idx} this is an error.
See list-index for possible values of {idx} and {end}.
Returns zero on error.
Example:

```
echo "last item: " .. remove(mylist, -1)
call remove(mylist, 0, 9)
```

Use delete() to remove a file.

Parameters:
- {list} (any[])
- {idx} (integer)
- {end} (integer?)

Return:
(any)

remove({blob}, {idx})
remove({blob}, {idx}, {end})
Without {end}: Remove the byte at {idx} from Blob {blob} and
return the byte.
With {end}: Remove bytes from {idx} to {end} (inclusive) and
return a Blob with these bytes. When {idx} points to the same
byte as {end} a Blob with one byte is returned. When {end}
points to a byte before {idx} this is an error.
Returns zero on error.
Example:

```
echo "last byte: " .. remove(myblob, -1)
call remove(mylist, 0, 9)
```

Parameters:
- {blob} (any)

- {idx} (integer)

- {end} (integer?)

Return:
(any)

remove({dict}, {key})
Lua: Prefer local value = dict[key]; dict[key] = nil for dicts; missing-key behavior differs.

Remove the entry from {dict} with key {key} and return it. Example:

```
echo "removed " .. remove(dict, "one")
```

If there is no {key} in {dict} this is an error. Returns zero on error.

Parameters:
- {dict} (any)

- {key} (string)

Return:
(any)

rename({from}, {to}) rename()

Lua: Prefer uv.fs_rename() or os.rename().

Rename the file by the name {from} to the name {to}. This should also work to move files across file systems. The result is a Number, which is 0 if the file was renamed successfully, and non-zero when the renaming failed. **NOTE:** If {to} exists it is overwritten without warning. This function is not available in the sandbox.

Parameters:
- {from} (string)

- {to} (string)

Return:
(integer)

repeat({expr}, {count}) repeat()

Lua: Prefer string.rep() for strings; lists need manual repetition.

Repeat {expr} {count} times and return the concatenated result. Example:

```
let separator = repeat('-', 80)
```

When {count} is zero or negative the result is empty. When {expr} is a List or a Blob the result is {expr} concatenated {count} times. Example:

```
let longlist = repeat(['a', 'b'], 3)
```

Results in ['a', 'b', 'a', 'b', 'a', 'b'].

Attributes:
api-fast

Parameters:
- {expr} (any)

- {count} (integer)

Return:
(any)

resolve({filename}) resolve() E655
On MS-Windows, when {filename} is a shortcut (a .lnk file), returns the path the shortcut points to in a simplified form. On Unix, repeat resolving symbolic links in all path components of {filename} and return the simplified result. To cope with link cycles, resolving of symbolic links is stopped after 100 iterations.

On other systems, return the simplified {filename}.
The simplification step is done as by simplify().
resolve() keeps a leading path component specifying the
current directory (provided the result is still a relative
path name) and also keeps a trailing path separator.

Attributes:
api-fast

Parameters:
- {filename} (string)

Return:
(string)

reverse({object}) reverse()

Lua: Prefer vim.iter(list):rev():totable() for lists;
strings, blobs, and in-place behavior differ.

Reverse the order of items in {object}. {object} can be a
List, a Blob or a String. For a List and a Blob the
items are reversed in-place and {object} is returned.
For a String a new String is returned.
Returns zero if {object} is not a List, Blob or a String.
If you want a List or Blob to remain unmodified make a copy
first:

```
let revlist = reverse(copy(mylist))
```

Parameters:
- {object} (T[])

Return:
(T[])

round({expr}) round()

Lua: Prefer
expr >= 0 and math.floor(expr + 0.5) or math.ceil(expr - 0.5)
for half-away-from-zero rounding.

Round off {expr} to the nearest integral value and return it
as a Float. If {expr} lies halfway between two integral
values, then use the larger one (away from zero).
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo round(0.456)
```

```
0.0
```

```
echo round(4.5)
```

```
5.0
```

```
echo round(-4.5)
```

```
-5.0
```

Parameters:
- {expr} (number)

Return:
(number)

rpcnotify({channel}, {event} [, {args}...]) rpcnotify()

Lua: Prefer vim.rpcnotify().

Sends {event} to {channel} via RPC and returns immediately.
If {channel} is 0, the event is broadcast to all channels.
Example:

```
au VimLeave call rpcnotify(0, "leaving")
```

Parameters:
- {channel} (integer)
- {event} (string)
- {...} (any)

Return:
(integer)

rpcrequest({channel}, {method} [, {args}...]) rpcrequest()

Lua: Prefer vim.rpcrequest().

Sends a request to {channel} to invoke {method} via
RPC and blocks until a response is received.
Example:

```
let result = rpcrequest(rpc_chan, "func", 1, 2, 3)
```

Parameters:
- {channel} (integer)
- {method} (string)
- {...} (any)

Return:
(any)

rubyeval({expr}) rubyeval()

Evaluate Ruby expression {expr} and return its result
converted to Vim data structures.
Numbers, floats and strings are returned as they are (strings
are copied though).
Arrays are represented as Vim List type.
Hashes are represented as Vim Dictionary type.
Other objects are represented as strings resulted from their
"Object#to_s" method.

Parameters:
- {expr} (any)

Return:
(any)

screenattr({row}, {col}) screenattr()

Like screenchar(), but return the attribute. This is a rather
arbitrary number that can only be used to compare to the
attribute at other positions.
Returns -1 when row or col is out of range.

Parameters:
- {row} (integer)
- {col} (integer)

Return:
(integer)

screenchar({row}, {col}) screenchar()

Returns the character at screen position [row, col] as a
Number. This works for every possible screen position, also
status lines, window separators and the command line. The
top left position is row one, column one. The character
excludes composing characters. For double-byte
encodings it may only be the first byte.
This is mainly to be used for testing.
Returns -1 when row or col is out of range.

Parameters:
- {row} (integer)
- {col} (integer)

Return:
(integer)

screenchars({row}, {col}) screenchars()

Returns the character and any composing characters at screen
position [row, col] as a List of Numbers. The first number
is the same as what screenchar() returns; further numbers
are composing characters on top of the base character.
This is mainly to be used for testing.
Returns an empty List when row or col is out of range.

Parameters:
- {row} (integer)

- {col} (integer)

Return:
(integer[])

screencol() screencol()

Returns the current screen column of the cursor. The
leftmost column has number 1.
This function is mainly used for testing.

Note: Always returns the current screen column, thus if used
in a command (e.g. ":echo screencol()") it will return the
column inside the command line, which is 1 when the command is
executed. To get the cursor position in the file use one of
the following mappings:

```
nnoremap <expr> GG ":echom " .. screencol() .. "\n"
nnoremap <silent> GG :echom screencol()<CR>
noremap GG <Cmd>echom screencol()<CR>
```

Return:
(integer)

screenpos({winid}, {lnum}, {col}) screenpos()

Returns the screen position of the text character in window
{winid} at buffer line {lnum} and column {col} as a Dict.
{col} is a one-based byte index.
The Dict has these members:
row screen row
col first screen column
endcol last screen column
curscol cursor screen column
If the specified position is not visible, all values are zero.
The "endcol" value differs from "col" when the character
occupies more than one screen cell. E.g. for a Tab "col" can
be 1 and "endcol" can be 8.
The "curscol" value is where the cursor would be placed. For
a Tab it would be the same as "endcol", while for a double
width character it would be the same as "col".
The conceal feature is ignored here, the column numbers are
as if 'conceallevel' is zero. You can set the cursor to the
right position and use screencol() to get the value with
conceal taken into account.
If the position is in a closed fold the screen position of the
first character is returned, {col} is not used.
Returns an empty Dict if {winid} is invalid.

Parameters:
- {winid} (integer)

- {lnum} (integer)

- {col} (integer)

Return:
({ col: integer, curscol: integer, endcol: integer, row: integer })

screenrow() screenrow()

Returns the current screen row of the cursor. The top line
has number one.
This function is mainly used for testing.
Alternatively you can use winline().

Note: Same restrictions as with screencol().

Return:
(integer)

screenstring({row}, {col}) screenstring()

Returns the base character and any composing characters at
screen position [row, col] as a String. This is like
screenchars() but returning a String with the characters.
This is mainly to be used for testing.
Returns an empty String when row or col is out of range.

Parameters:
- {row} (integer)

- {col} (integer)

Return:
(string)

search({pattern} [, {flags} [, {stopline} [, {timeout} [, {skip}]]]]) search()
Search for regexp pattern {pattern}. The search starts at the cursor position (you can use cursor() to set it).

When a match has been found its line number is returned. If there is no match a 0 is returned and the cursor doesn't move. No error message is given. To get the matched string, use matchbufline().

{flags} is a String, which can contain these character flags:
'b' search Backward instead of forward
'c' accept a match at the Cursor position
'e' move to the End of the match
'n' do Not move the cursor
'p' return number of matching sub-Pattern (see below)
's' Set the ' mark at the previous location of the cursor
'w' Wrap around the end of the file
'W' don't Wrap around the end of the file
'z' start searching at the cursor column instead of Zero
If neither 'w' or 'W' is given, the 'wrapscan' option applies.

If the 's' flag is supplied, the ' mark is set, only if the cursor is moved. The 's' flag cannot be combined with the 'n' flag.

'ignorecase', 'smartcase' and 'magic' are used.

When the 'z' flag is not given, forward searching always starts in column zero and then matches before the cursor are skipped. When the 'c' flag is present in 'cpo' the next search starts after the match. Without the 'c' flag the next search starts one column after the start of the match. This matters for overlapping matches. See cpo-c. You can also insert "\ze" to change where the match ends, see /\ze.

When searching backwards and the 'z' flag is given then the search starts in column zero, thus no match in the current line will be found (unless wrapping around the end of the file).

When the {stopline} argument is given then the search stops after searching this line. This is useful to restrict the search to a range of lines. Examples:

```
let match = search('(', 'b', line("w0"))
let end = search('END', '', line("w$"))
```

When {stopline} is used and it is not zero this also implies that the search does not wrap around the end of the file. A zero value is equal to not giving the argument.

When the {timeout} argument is given the search stops when more than this many milliseconds have passed. Thus when {timeout} is 500 the search stops after half a second. The value must not be negative. A zero value is like not giving the argument.

Note: the timeout is only considered when searching, not while evaluating the {skip} expression.

If the {skip} expression is given it is evaluated with the cursor positioned on the start of a match. If it evaluates to non-zero this match is skipped. This can be used, for example, to skip a match in a comment or a string. {skip} can be a string, which is evaluated as an expression, a function reference or a lambda. When {skip} is omitted or empty, every match is accepted. When evaluating {skip} causes an error the search is aborted and -1 returned.

search()-sub-match

With the 'p' flag the returned value is one more than the first sub-match in \(\). One if none of them matched but the whole pattern did match. To get the column number too use searchpos().

The cursor will be positioned at the match, unless the 'n' flag is used.

Example (goes over all files in the argument list):

```
let n = 1
while n <= argc()           " loop over all files in arglist
  exe "argument " .. n
  " start at the last char in the file and wrap for the
  " first search to find match at start of file
  normal G$
  let flags = "w"
  while search("foo", flags) > 0
    s/foo/bar/g
    let flags = "W"
  endwhile
  update                    " write the file if modified
  let n = n + 1
endwhile
```

Example for using some flags:

```
echo search('\<if\|\(else\)\|\(endif\)', 'ncpe')
```

This will search for the keywords "if", "else", and "endif"
under or after the cursor. Because of the 'p' flag, it
returns 1, 2, or 3 depending on which keyword is found, or 0
if the search fails. With the cursor on the first word of the
line:

```
if (foo == 0) | let foo = foo + 1 | endif
```

the function returns 1. Without the 'c' flag, the function
finds the "endif" and returns 3. The same thing happens
without the 'e' flag if the cursor is on the "f" of "if".
The 'n' flag tells the function not to move the cursor.

Parameters:

- {pattern} (string)
- {flags} (string?)
- {stopline} (integer?)
- {timeout} (integer?)
- {skip} (string|function?)

Return:

(integer)

searchcount([{options}]) searchcount()

Get or update the last search count, like what is displayed
without the "S" flag in 'shortmess'. This works even if
'shortmess' does contain the "S" flag.

This returns a Dictionary. The dictionary is empty if the
previous pattern was not set and "pattern" was not specified.

key	type	meaning
current	Number	current position of match; 0 if the cursor position is before the first match
exact_match	Boolean	1 if "current" is matched on "pos", otherwise 0
total	Number	total count of matches found
incomplete	Number	0: search was fully completed 1: recomputing was timed out 2: max count exceeded

For {options} see further down.

To get the last search count when n or N was pressed, call
this function with recompute: 0 . This sometimes returns
wrong information because of 'maxsearchcount'.
If the count exceeded 'maxsearchcount', the result must be
'maxsearchcount' + 1. If you want to get correct information,
specify recompute: 1:

```
" result == 'maxsearchcount' + 1 when many matches
let result = searchcount(#{recompute: 0})

" Below returns correct result (recompute defaults
" to 1)
let result = searchcount()
```

The function is useful to add the count to 'statusline':

```
function! LastSearchCount() abort
  let result = searchcount(#{recompute: 0})
  if empty(result)
    return ''
  endif
  if result.incomplete ==# 1     " timed out
    return printf(' /%s [?/??]', @/)
  elseif result.incomplete ==# 2 " max count exceeded
    if result.total > result.maxcount &&
    \  result.current > result.maxcount
      return printf(' /%s [>%d/>%d]', @/,
      \             result.current, result.total)
    elseif result.total > result.maxcount
      return printf(' /%s [%d/>%d]', @/,
      \             result.current, result.total)
    endif
  endif
  return printf(' /%s [%d/%d]', @/,
  \             result.current, result.total)
endfunction
let &statusline ..= '%{LastSearchCount()}'

" Or if you want to show the count only when
" 'hlsearch' was on
" let &statusline ..=
" \   '%{v:hlsearch ? LastSearchCount() : ""}'
```

You can also update the search count, which can be useful in a CursorMoved or CursorMovedI autocommand:

```
autocmd CursorMoved,CursorMovedI *
  \ let s:searchcount_timer = timer_start(
  \   200, function('s:update_searchcount'))
function! s:update_searchcount(timer) abort
  if a:timer ==# s:searchcount_timer
    call searchcount(#{
    \ recompute: 1, maxcount: 0, timeout: 100})
    redrawstatus
  endif
endfunction
```

This can also be used to count matched texts with specified pattern in the current buffer using "pattern":

```
" Count '\<foo\>' in this buffer
" (Note that it also updates search count)
let result = searchcount(#{pattern: '\<foo\>'})

" To restore old search count by old pattern,
" search again
call searchcount()
```

{options} must be a Dictionary. It can contain:

key	type	meaning
recompute	Boolean	if TRUE, recompute the count like n or N was executed. otherwise returns the last computed result (when n or N was used when "S" is not in 'shortmess', or this function was called). (default: TRUE)
pattern	String	recompute if this was given and different with @/. this works as same as the below command is executed before calling this function

```
let @/ = pattern
```

		(default: @/)
timeout	Number	0 or negative number is no timeout. timeout milliseconds for recomputing the result (default: 0)
maxcount	Number	0 or negative number is no limit. max count of matched text while recomputing the result. if search exceeded total count, "total" value becomes maxcount + 1 (default: 'maxsearchcount')
pos	List	[lnum, col, off] value when recomputing the result. this changes "current" result value. see cursor(), getpos() (default: cursor's position)

Parameters:
- {options} (table?)

Return:
(any)

searchdecl({name} [, {global} [, {thisblock}]]) searchdecl()

Search for the declaration of {name}.

With a non-zero {global} argument it works like gD, find first match in the file. Otherwise it works like gd, find first match in the function.

With a non-zero {thisblock} argument matches in a {} block that ends before the cursor position are ignored. Avoids finding variable declarations only valid in another scope.

Moves the cursor to the found match.
Returns zero for success, non-zero for failure.
Example:

```
if searchdecl('myvar') == 0
   echo getline('.')
endif
```

Parameters:
- {name} (string)
- {global} (boolean?)
- {thisblock} (boolean?)

Return:
(any)

searchpair()

searchpair({start}, {middle}, {end} [, {flags} [, {skip} [, {stopline} [, {timeout}]]]])
Search for the match of a nested start-end pair. This can be used to find the "endif" that matches an "if", while other if/endif pairs in between are ignored.
The search starts at the cursor. The default is to search forward, include 'b' in {flags} to search backward.
If a match is found, the cursor is positioned at it and the line number is returned. If no match is found 0 or -1 is returned and the cursor doesn't move. No error message is given.

{start}, {middle} and {end} are patterns, see pattern. They must not contain \(\) pairs. Use of \%(\) is allowed. When {middle} is not empty, it is found when searching from either direction, but only when not in a nested start-end pair. A typical use is:

```
echo searchpair('\<if\>', '\<else\>', '\<endif\>')
```

By leaving {middle} empty the "else" is skipped.

{flags} 'b', 'c', 'n', 's', 'w' and 'W' are used like with search(). Additionally:
'r' Repeat until no more matches found; will find the outer pair. Implies the 'W' flag.
'm' Return number of matches instead of line number with the match; will be > 1 when 'r' is used.
Note: it's nearly always a good idea to use the 'W' flag, to avoid wrapping around the end of the file.

When a match for {start}, {middle} or {end} is found, the {skip} expression is evaluated with the cursor positioned on the start of the match. It should return non-zero if this match is to be skipped. E.g., because it is inside a comment or a string.
When {skip} is omitted or empty, every match is accepted.
When evaluating {skip} causes an error the search is aborted and -1 returned.
{skip} can be a string, a lambda, a funcref or a partial.
Anything else makes the function fail.

For {stopline} and {timeout} see search().

The value of 'ignorecase' is used. 'magic' is ignored, the patterns are used like it's on.

The search starts exactly at the cursor. A match with {start}, {middle} or {end} at the next character, in the direction of searching, is the first one found. Example:

```
if 1
  if 2
  endif 2
endif 1
```

When starting at the "if 2", with the cursor on the "i", and searching forwards, the "endif 2" is found. When starting on the character just before the "if 2", the "endif 1" will be found. That's because the "if 2" will be found first, and then this is considered to be a nested if/endif from "if 2" to "endif 2".
When searching backwards and {end} is more than one character, it may be useful to put "\zs" at the end of the pattern, so that when the cursor is inside a match with the end it finds the matching start.

Example, to find the "endif" command in a Vim script:

```
echo searchpair('\<if\>', '\<el\%[seif]\>', '\<en\%[dif]\>', 'W',
\ 'getline(".") =~ "^\\s*\""')
```

The cursor must be at or after the "if" for which a match is to be found. Note that single-quote strings are used to avoid having to double the backslashes. The skip expression only catches comments at the start of a line, not after a command. Also, a word "en" or "if" halfway through a line is considered a match.
Another example, to search for the matching "{" of a "}":

```
echo searchpair('{', '', '}', 'bW')
```

This works when the cursor is at or before the "}" for which a match is to be found. To reject matches that syntax highlighting recognized as strings:

```
echo searchpair('{', '', '}', 'bW',
     \ 'synIDattr(synID(line("."), col("."), 0), "name") =~? "string"')
```

Parameters:

- {start} (string)
- {middle} (string)
- {end} (string)
- {flags} (string?)
- {skip} (string|function?)
- {stopline} (integer?)
- {timeout} (integer?)

Return:
(integer)

searchpairpos()

searchpairpos({start}, {middle}, {end} [, {flags} [, {skip} [, {stopline} [, {timeout}]]]])
Same as searchpair(), but returns a List with the line and column position of the match. The first element of the List is the line number and the second element is the byte index of the column position of the match. If no match is found, returns [0, 0].

```
let [lnum,col] = searchpairpos('{', '', '}', 'n')
```

See match-parens for a bigger and more useful example.

Parameters:

- {start} (string)
- {middle} (string)
- {end} (string)

- {flags} (string?)
- {skip} (string|function?)
- {stopline} (integer?)
- {timeout} (integer?)

Return:
([integer, integer])

searchpos()

searchpos({pattern} [, {flags} [, {stopline} [, {timeout} [, {skip}]]]])
Same as search(), but returns a List with the line and column position of the match. The first element of the List is the line number and the second element is the byte index of the column position of the match. If no match is found, returns [0, 0].
Example:

```
let [lnum, col] = searchpos('mypattern', 'n')
```

When the 'p' flag is given then there is an extra item with the sub-pattern match number search()-sub-match. Example:

```
let [lnum, col, submatch] = searchpos('\(\l\)\|\(\u\)', 'np')
```

In this example "submatch" is 2 when a lowercase letter is found /\l, 3 when an uppercase letter is found /\u.

Parameters:
- {pattern} (string)
- {flags} (string?)
- {stopline} (integer?)
- {timeout} (integer?)
- {skip} (string|function?)

Return:
({ [1]: integer, [2]: integer, [3]: integer? })

serverlist([{opts}])

serverlist()

Returns a list of server addresses, or empty if all servers were stopped. serverstart() serverstop()

The optional argument {opts} is a Dict and supports the following items:

peer : If TRUE, servers not started by serverstart() will also be returned. (default: FALSE)
Not supported on Windows yet.

info : If TRUE, return a list of Dicts with detailed info instead of addresses. Implies peer=true. Each Dict has the following items:

addr	(string)	Server address.
pid	(number)	PID of the Nvim process.
own	(bool)	Whether this server belongs to the current Nvim instance.
active	(number)	v:useractive of the server.

(default: FALSE)

Example:

```
echo serverlist()
echo serverlist(#{info: v:true})
```

Parameters:
- {opts} (table?)

Return:
(string[]|vim.ServerInfo[])

serverstart([{address}])

serverstart()

Opens a socket or named pipe at {address} and listens for RPC messages. Clients can send API commands to the returned address to control Nvim.

Returns the address string (which may differ from the
{address} argument, see below).

- If {address} has a colon (":") it is a TCP/IPv4/IPv6 address

  where the last ":" separates host and port (empty or zero
  assigns a random port).
- Else {address} is the path to a named pipe (except on Windows).

  - If {address} has no slashes ("/") it is treated as the

    "name" part of a generated path in this format:

    ```
    stdpath("run")."/{name}.{pid}.{counter}"
    ```

  - If {address} is omitted the name is "nvim".

    ```
    echo serverstart()
    ```

    ```
    => /tmp/nvim.bram/oknANW/nvim.15430.5
    ```

Example bash command to list all Nvim servers:

```
ls ${XDG_RUNTIME_DIR:-${TMPDIR}nvim.${USER}}/*/nvim.*.0
```

Example named pipe:

```
if has('win32')
  echo serverstart('//./pipe/nvim-pipe-1234')
else
  echo serverstart('nvim.sock')
endif
```

Example TCP/IP address:

```
echo serverstart('::1:12345')
```

Parameters:
- {address} (string?)

Return:
(string)

serverstop({address}) serverstop()

Closes the pipe or socket at {address}.
Returns TRUE if {address} is valid, else FALSE.
If v:servername is stopped it is set to the next available
address in serverlist().

Parameters:
- {address} (string)

Return:
(integer)

setbufline({buf}, {lnum}, {text}) setbufline()

Lua: Prefer nvim_buf_set_lines().

Set line {lnum} to {text} in buffer {buf}. This works like
setline() for the specified buffer.

This function works only for loaded buffers. First call
bufload() if needed.

To insert lines use appendbufline().

{text} can be a string to set one line, or a List of strings
to set multiple lines. If the List extends below the last
line then those lines are added. If the List is empty then
nothing is changed and zero is returned.

For the use of {buf}, see bufname() above.

{lnum} is used like with setline().
Use "$" to refer to the last line in buffer {buf}.
When {lnum} is just below the last line the {text} will be
added below the last line.
On success 0 is returned, on failure 1 is returned.

If {buf} is not a valid buffer or {lnum} is not valid, an
error message is given.

Parameters:
- {buf} (integer|string)

- {lnum} (integer)

- {text} (string|string[])

Return:
(integer)

setbufvar({buf}, {varname}, {val}) setbufvar()

Lua: Prefer nvim_buf_set_var() or vim.b after resolving {buf} to a bufnr; option names use nvim_set_option_value().

Set option or local variable {varname} (string, without "b:") in buffer {buf} to {val}. Also works for a global or window-local option (not variable). A window-local option is set in a window of the current tabpage that displays {buf}, and the global value is unchanged. When no window in the current tabpage displays {buf} the option is not set and no error is given; use setwinvar() or win_execute() for that.

For the use of {buf}, see bufname() above.

Examples:

```
call setbufvar(1, "&mod", 1)
call setbufvar("todo", "myvar", "foobar")
```

This function is not available in the sandbox.

Parameters:
- {buf} (integer|string)

- {varname} (string)

- {val} (any)

Return:
(any)

setcellwidths({list}) setcellwidths()

Specify overrides for cell widths of character ranges. This tells Vim how wide characters are when displayed in the terminal, counted in screen cells. The values override 'ambiwidth'. Example:

```
call setcellwidths([
            \ [0x111, 0x111, 1],
            \ [0x2194, 0x2199, 2],
            \ ])
```

The {list} argument is a List of Lists with each three numbers: [{low}, {high}, {width}]. E1109 E1110
{low} and {high} can be the same, in which case this refers to one character. Otherwise it is the range of characters from {low} to {high} (inclusive). E1111 E1114
Only characters with value 0x80 and higher can be used.

{width} must be either 1 or 2, indicating the character width in screen cells. E1112

An error is given if the argument is invalid, also when a range overlaps with another. E1113

If the new value causes 'fillchars' or 'listchars' to become invalid it is rejected and an error is given.

To clear the overrides pass an empty {list}:

```
call setcellwidths([])
```

You can use the script $VIMRUNTIME/scripts/emoji_list.lua to see the effect for known emoji characters. Move the cursor through the text to check if the cell widths of your terminal match with what Vim knows about each emoji. If it doesn't look right you need to adjust the {list} argument.

getcellwidths() can be used to get the overrides later.

Parameters:
- {list} (any[])

Return:
(any)

setcharpos({expr}, {list}) setcharpos()

Lua: Prefer nvim_win_set_cursor() or nvim_buf_set_mark()

with vim.str_byteindex(); special positions, off, and
curswant differ.

Same as setpos() but uses the specified column number as the
character index instead of the byte index in the line.

Example:
With the text "□□□□" in line 8:

```
call setcharpos('.', [0, 8, 4, 0])
```

positions the cursor on the fourth character '□'.

```
call setpos('.', [0, 8, 4, 0])
```

positions the cursor on the second character '□'.

Parameters:
- {expr} (string)

- {list} (integer[])

Return:
(any)

setcharsearch({dict}) setcharsearch()

Set the current character search information to {dict},
which contains one or more of the following entries:

char	character which will be used for a subsequent , or ; command; an empty string clears the character search
forward	direction of character search; 1 for forward, 0 for backward
until	type of character search; 1 for a t or T character search, 0 for an f or F character search

This can be useful to save/restore a user's character search
from a script:

```
let prevsearch = getcharsearch()
" Perform a command which clobbers user's search
call setcharsearch(prevsearch)
```

Also see getcharsearch().

Parameters:
- {dict} ({ char?: string, forward?: 1|0, until?: 1|0 })

Return:
(any)

setcmdline({str} [, {pos}]) setcmdline()

Set the command line to {str} and set the cursor position to
{pos}.
If {pos} is omitted, the cursor is positioned after the text.
Returns 0 when successful, 1 when not editing the command
line.

Parameters:
- {str} (string)

- {pos} (integer?)

Return:
(integer)

setcmdpos({pos}) setcmdpos()

Set the cursor position in the command line to byte position
{pos}. The first position is 1.
Use getcmdpos() to obtain the current position.
Only works while editing the command line, thus you must use
c_CTRL-_e, c_CTRL-R_= or c_CTRL-R_CTRL-R with '='. For
c_CTRL-_e and c_CTRL-R_CTRL-R with '=' the position is
set after the command line is set to the expression. For
c_CTRL-R_= it is set after evaluating the expression but
before inserting the resulting text.
When the number is too big the cursor is put at the end of the
line. A number smaller than one has undefined results.
Returns 0 when successful, 1 when not editing the command
line.

Parameters:
- {pos} (integer)

Return:
(any)

setcursorcharpos({lnum}, {col} [, {off}]) setcursorcharpos()

Lua: Prefer nvim_win_set_cursor() with vim.str_byteindex(); off, return values, and special line forms differ.

setcursorcharpos({list})
Lua: Prefer nvim_win_set_cursor() with vim.str_byteindex(); list shape, off, and return values differ.

Same as cursor() but uses the specified column number as the character index instead of the byte index in the line.

Example:
With the text "□□□□" in line 4:

```
call setcursorcharpos(4, 3)
```

positions the cursor on the third character '□'.

```
call cursor(4, 3)
```

positions the cursor on the first character '□'.

Returns 0 when the position could be set, -1 otherwise.

Parameters:
- {list} (integer[])

Return:
(any)

setenv({name}, {val}) setenv()

Lua: Prefer vim.env.

Set environment variable {name} to {val}. Example:

```
call setenv('HOME', '/home/myhome')
```

When {val} is v:null the environment variable is deleted.
See also expr-env.

Parameters:
- {name} (string)
- {val} (string)

Return:
(any)

setfperm({fname}, {mode}) setfperm() chmod
Lua: Prefer uv.fs_chmod().

Set the file permissions for {fname} to {mode}.
{mode} must be a string with 9 characters. It is of the form "rwxrwxrwx", where each group of "rwx" flags represent, in turn, the permissions of the owner of the file, the group the file belongs to, and other users. A '-' character means the permission is off, any other character means on. Multi-byte characters are not supported.

For example "rw-r-----" means read-write for the user, readable by the group, not accessible by others. "xx-x-----" would do the same thing.

Returns non-zero for success, zero for failure.

To read permissions see getfperm().

Parameters:
- {fname} (string)
- {mode} (string)

Return:
(any)

setline({lnum}, {text}) setline()

Lua: Prefer nvim_set_current_line() or nvim_buf_set_lines().

Set line {lnum} of the current buffer to {text}. To insert lines use append(). To set lines in another buffer use setbufline().

{lnum} is used like with getline().
When {lnum} is just below the last line the {text} will be added below the last line.

{text} can be any type or a List of any type, each item is converted to a String. When {text} is an empty List then nothing is changed and FALSE is returned.

If this succeeds, FALSE is returned. If this fails (most likely because {lnum} is invalid) TRUE is returned.

Example:

```
call setline(5, strftime("%c"))
```

When {text} is a List then line {lnum} and following lines will be set to the items in the list. Example:

```
call setline(5, ['aaa', 'bbb', 'ccc'])
```

This is equivalent to:

```
for [n, l] in [[5, 'aaa'], [6, 'bbb'], [7, 'ccc']]
  call setline(n, l)
endfor
```

Note: The '[and '] marks are not set.

Parameters:

- {lnum} (integer|string)
- {text} (any)

Return:

(any)

setloclist({nr}, {list} [, {action} [, {what}]]) setloclist()

Create or replace or add to the location list for window {nr} (window-number or window-ID).
When {nr} is zero the current window is used.

For a location list window, the displayed location list is modified. For an invalid {nr}, -1 is returned.
Otherwise, same as setqflist().
Also see location-list.

For {action} see setqflist-action.

If the optional {what} dictionary argument is supplied, then only the items listed in {what} are set. Refer to setqflist() for the list of supported keys in {what}.

Parameters:

- {nr} (integer)
- {list} (vim.quickfix.entry[])
- {action} (string?)
- {what} (vim.fn.setqflist.what?)

Return:

(any)

setmatches({list} [, {win}]) setmatches()

Restores a list of matches saved by getmatches() for the current window. Returns 0 if successful, otherwise -1. All current matches are cleared before the list is restored. See example for getmatches().
{win} (if given) is a window-number or window-ID.

Parameters:

- {list} (vim.fn.getmatches.ret.item[])
- {win} (integer?)

Return:

(any)

setpos({expr}, {list}) setpos()

Lua: Prefer nvim_win_set_cursor() for "." or nvim_buf_set_mark() for marks; special positions, off, and curswant differ.

Set the position for String {expr}. Possible values:

```
.       the cursor
'x      mark x
```

{list} must be a List with four or five numbers:
    [bufnum, lnum, col, off]
    [bufnum, lnum, col, off, curswant]

"bufnum" is the buffer number. Zero can be used for the current buffer. When setting an uppercase mark "bufnum" is used for the mark position. For other marks it specifies the buffer to set the mark in. You can use the bufnr() function to turn a file name into a buffer number.
For setting the cursor and the ' mark "bufnum" is ignored, since these are associated with a window, not a buffer.
Does not change the jumplist.

"lnum" and "col" are the position in the buffer. The first column is 1. Use a zero "lnum" to delete a mark. If "col" is smaller than 1 then 1 is used. To use the character count instead of the byte count, use setcharpos().

The "off" number is only used when 'virtualedit' is set. Then it is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character.

The "curswant" number is only used when setting the cursor position. It sets the preferred column for when moving the cursor vertically. When the "curswant" number is missing the preferred column is not set. When it is present and setting a mark position it is not used.

Note that for '< and '> changing the line number may result in the marks to be effectively swapped, so that '< is always before '>.

The visual marks '< and '> refer to the beginning and end of the visual selection relative to the cursor position.
Note that this differs from getpos(), where they are relative to the buffer.

Returns 0 when the position could be set, -1 otherwise.
An error message is given if {expr} is invalid.

Also see setcharpos(), getpos() and getcurpos().

This does not restore the preferred column for moving vertically; if you set the cursor position with this, j and k motions will jump to previous columns! Use cursor() to also set the preferred column. Also see the "curswant" key in winrestview().

Parameters:

- {expr} (string)
- {list} (integer[])

Return:

(any)

setqflist({list} [, {action} [, {what}]]) setqflist()

Create or replace or add to the quickfix list.

If the optional {what} dictionary argument is supplied, then only the items listed in {what} are set. The first {list} argument is ignored. See below for the supported items in {what}.

setqflist-what

When {what} is not present, the items in {list} are used. Each item must be a dictionary. Non-dictionary items in {list} are ignored. Each dictionary item can contain the following entries:

bufnr	buffer number; must be the number of a valid buffer
filename	name of a file; only used when "bufnr" is not present or it is invalid.
module	name of a module; if given it will be used in quickfix error window instead of the filename.
lnum	line number in the file
end_lnum	end of lines, if the item spans multiple lines
pattern	search pattern used to locate the error
col	column number
vcol	when non-zero: "col" is visual column when zero: "col" is byte index
end_col	end column, if the item spans multiple columns
nr	error number
text	description of the error
type	single-character error type, 'E', 'W', etc.
valid	recognized error message
user_data	custom data associated with the item, can be any type.

The "col", "vcol", "nr", "type" and "text" entries are optional. Either "lnum" or "pattern" entry can be used to

locate a matching error line.
If the "filename" and "bufnr" entries are not present or
neither the "lnum" or "pattern" entries are present, then the
item will not be handled as an error line.
If both "pattern" and "lnum" are present then "pattern" will
be used.
If the "valid" entry is not supplied, then the valid flag is
set when "bufnr" is a valid buffer or "filename" exists.
If you supply an empty {list}, the quickfix list will be
cleared.
Note that the list is not exactly the same as what
getqflist() returns.

{action} values: setqflist-action E927

'a' The items from {list} are added to the existing quickfix list. If there is no existing list, then a new list is created.

'r' The items from the current quickfix list are replaced with the items from {list}. This can also be used to clear the list:

```
call setqflist([], 'r')
```

'u' Like 'r', but tries to preserve the current selection in the quickfix list. The entry nearest to the previously selected one becomes the current entry. Proximity is determined by comparing the file, then the line number and then the column number.

'f' All the quickfix lists in the quickfix stack are freed.

If {action} is not present or is set to ' ', then a new list is created. The new quickfix list is added after the current quickfix list in the stack and all the following lists are freed. To add a new quickfix list at the end of the stack, set "nr" in {what} to "$".

The following items can be specified in dictionary {what}:

- context: quickfix list context. See quickfix-context
- efm: errorformat to use when parsing text from "lines". If this is not present, then the 'errorformat' option value is used. See quickfix-parse
- id: quickfix list identifier quickfix-ID
- idx: index of the current entry in the quickfix list specified by "id" or "nr". If set to '$', then the last entry in the list is set as the current entry. See quickfix-index
- items: list of quickfix entries. Same as the {list} argument.
- lines: use 'errorformat' to parse a list of lines and add the resulting entries to the quickfix list {nr} or {id}. Only a List value is supported. See quickfix-parse
- nr: list number in the quickfix stack; zero means the current quickfix list and "$" means the last quickfix list.
- quickfixtextfunc: function to get the text to display in the quickfix window. The value can be the name of a function or a funcref or a lambda. Refer to quickfix-window-function for an explanation of how to write the function and an example.
- title: quickfix list title text. See quickfix-title

Unsupported keys in {what} are ignored.
If the "nr" item is not present, then the current quickfix list is modified. When creating a new quickfix list, "nr" can be set to a value one greater than the quickfix stack size.
When modifying a quickfix list, to guarantee that the correct list is modified, "id" should be used instead of "nr" to specify the list.

Examples (See also setqflist-examples):

```
call setqflist([], 'r', {'title': 'My search'})
call setqflist([], 'r', {'nr': 2, 'title': 'Errors'})
call setqflist([], 'a', {'id':qfid, 'lines':["F1:10:L10"]})
```

Returns zero for success, -1 for failure.

This function can be used to create a quickfix list independent of the 'errorformat' setting. Use a command like :cc 1 to jump to the first position.

Parameters:

- {list} (vim.quickfix.entry[])
- {action} (string?)
- {what} (vim.fn.setqflist.what?)

Return:
(integer)

setreg({regname}, {value} [, {options}]) setreg()

Set the register {regname} to {value}.
If {regname} is "" or "@", the unnamed register '"' is used.
The {regname} argument is a string.

{value} may be any value returned by getreg() or
getreginfo(), including a List or Dict.
If {options} contains "a" or {regname} is upper case,
then the value is appended.

{options} can also contain a register type specification:
    "c" or "v"   charwise mode
    "l" or "V"   linewise mode
    "b" or "<CTRL-V>" blockwise-visual mode
If a number immediately follows "b" or "<CTRL-V>" then this is
used as the width of the selection - if it is not specified
then the width of the block is set to the number of characters
in the longest line (counting a <Tab> as 1 character).
If {options} contains "u" or '"', then the unnamed register is
set to point to register {regname}.

If {options} contains no register settings, then the default
is to use character mode unless {value} ends in a <NL> for
string {value} and linewise mode for list {value}. Blockwise
mode is never selected automatically.
Returns zero for success, non-zero for failure.

E883

Note: you may not use List containing more than one item to
set search and expression registers. Lists containing
no items act like empty strings.

Examples:

```
call setreg(v:register, @*)
call setreg('*', @%, 'ac')
call setreg('a', "1\n2\n3", 'b5')
call setreg('"', { 'points_to': 'a'})
```

This example shows using the functions to save and restore a
register:

```
let var_a = getreginfo()
call setreg('a', var_a)
```

or:

```
let var_a = getreg('a', 1, 1)
let var_amode = getregtype('a')
" ....
call setreg('a', var_a, var_amode)
```

Note: you may not reliably restore register value
without using the third argument to getreg() as without it
newlines are represented as newlines AND Nul bytes are
represented as newlines as well, see NL-used-for-Nul.

You can also change the type of a register by appending
nothing:

```
call setreg('a', '', 'al')
```

Parameters:
- {regname} (string)
- {value} (any)
- {options} (string?)

Return:
(any)

settabvar({tabnr}, {varname}, {val}) settabvar()

Lua: Prefer nvim_tabpage_set_var() or vim.t.

Set tab-local variable {varname} to {val} in tabpage {tabnr}.
t:var
The {varname} argument is a string.
Note that the variable name without "t:" must be used.
Tabs are numbered starting with one.
This function is not available in the sandbox.

Parameters:
- {tabnr} (integer)

- {varname} (string)

- {val} (any)

Return:
(any)

settabwinvar({tabnr}, {winnr}, {varname}, {val}) settabwinvar()

Lua: Prefer nvim_win_set_var() or vim.w after resolving {tabnr} and {winnr} to a winid; option names use nvim_set_option_value().

Set option or local variable {varname} in window {winnr} to {val}.
Tabs are numbered starting with one. For the current tabpage use setwinvar().
{winnr} is a window-number or window-ID.
When {winnr} is zero the current window is used.
This also works for a global or local buffer option, but it doesn't work for a global or local buffer variable.
For a local buffer option the global value is unchanged.
Note that the variable name without "w:" must be used.
Examples:

```
call settabwinvar(1, 1, "&list", 0)
call settabwinvar(3, 2, "myvar", "foobar")
```

This function is not available in the sandbox.

Parameters:
- {tabnr} (integer)

- {winnr} (integer)

- {varname} (string)

- {val} (any)

Return:
(any)

settagstack({nr}, {dict} [, {action}]) settagstack()

Modify the tag stack of the window {nr} (window-number or window-ID) using {dict}.

For a list of supported items in {dict}, refer to gettagstack(). "curidx" takes effect before changing the tag stack.

E962

How the tag stack is modified depends on the {action} argument:
- If {action} is not present or is set to 'r', then the tag stack is replaced.
- If {action} is set to 'a', then new entries from {dict} are pushed (added) onto the tag stack.
- If {action} is set to 't', then all the entries from the current entry in the tag stack or "curidx" in {dict} are removed and then new entries are pushed to the stack.

The current index is set to one after the length of the tag stack after the modification.

Returns zero for success, -1 for failure.

Examples (for more examples see tagstack-examples):
Empty the tag stack of window 3:

```
call settagstack(3, {'items' : []})
```

Save and restore the tag stack:

```
let stack = gettagstack(1003)
" do something else
call settagstack(1003, stack)
unlet stack
```

Parameters:

- {nr} (integer)
- {dict} (any)
- {action} (string?)

Return:
(any)

setwinvar({nr}, {varname}, {val}) setwinvar()

Lua: Prefer nvim_win_set_var() or vim.w after resolving
{nr} to a winid; option names use nvim_set_option_value().

Like settabwinvar() for the current tabpage.
Examples:

```
call setwinvar(1, "&list", 0)
call setwinvar(2, "myvar", "foobar")
```

Parameters:
- {nr} (integer)
- {varname} (string)
- {val} (any)

Return:
(any)

sha256({expr}) sha256()

Returns a String with 64 hex characters, which is the SHA256
checksum of {expr}.
{expr} is a String or a Blob.

Parameters:
- {expr} (string)

Return:
(string)

shellescape({string} [, {special}]) shellescape()

Lua: Prefer vim.system() with list args to avoid shell
escaping; :! and {special} semantics differ.

Escape {string} for use as a shell command argument.

On Windows when 'shellslash' is not set, encloses {string} in
double-quotes and doubles all double-quotes within {string}.
Otherwise encloses {string} in single-quotes and replaces all
"'" with "'\''".

The {special} argument adds additional escaping of keywords
used in Vim commands. If it is a non-zero-arg:
- Special items such as "!", "%", "#" and "<cword>" (as listed
  in expand()) will be preceded by a backslash.
  The backslash will be removed again by the :! command.
- The <NL> character is escaped.

If 'shell' contains "csh" in the tail:
- The "!" character will be escaped. This is because csh and
  tcsh use "!" for history replacement even in single-quotes.
- The <NL> character is escaped (twice if {special} is
  a non-zero-arg).

If 'shell' contains "fish" in the tail, the "\" character will
be escaped because in fish it is used as an escape character
inside single quotes.

Example of use with a :! command:

```
exe '!dir ' .. shellescape(expand('<cfile>'), 1)
```

This results in a directory listing for the file under the
cursor. Example of use with system():

```
call system("chmod +w -- " .. shellescape(expand("%")))
```

See also ::S.

Parameters:

- {string} (string)

- {special} (boolean?)

Return:

(string)

shiftwidth([{col}]) shiftwidth()

Lua: Prefer vim.bo for simple cases:
vim.bo.shiftwidth > 0 and vim.bo.shiftwidth or vim.bo.tabstop;
{col} and 'vartabstop' semantics differ.

Returns the effective value of 'shiftwidth'. This is the
'shiftwidth' value unless it is zero, in which case it is the
'tabstop' value. To be backwards compatible in indent
plugins, use this:

```
if exists('*shiftwidth')
  func s:sw()
    return shiftwidth()
  endfunc
else
  func s:sw()
    return &sw
  endfunc
endif
```

And then use s:sw() instead of &sw.

for which to return the 'shiftwidth' value. This matters for
the 'vartabstop' feature. If the 'vartabstop' setting is
enabled and no {col} argument is given, column 1 will be
assumed.

Parameters:

- {col} (integer?)

Return:

(integer)

sign_define({name} [, {dict}]) sign_define()

sign_define({list})

Define a new sign named {name} or modify the attributes of an
existing sign. This is similar to the :sign-define command.

Prefix {name} with a unique text to avoid name collisions.
There is no {group} like with placing signs.

The {name} can be a String or a Number. The optional {dict}
argument specifies the sign attributes. The following values
are supported:

icon	full path to the bitmap file for the sign.
linehl	highlight group used for the whole line the sign is placed in.
priority	default priority value of the sign
numhl	highlight group used for the line number where the sign is placed.
text	text that is displayed when there is no icon or the GUI is not being used.
texthl	highlight group used for the text item
culhl	highlight group used for the text item when the cursor is on the same line as the sign and 'cursorline' is enabled.

If the sign named {name} already exists, then the attributes
of the sign are updated.

The one argument {list} can be used to define a list of signs.
Each list item is a dictionary with the above items in {dict}
and a "name" item for the sign name.

Returns 0 on success and -1 on failure. When the one argument
{list} is used, then returns a List of values one for each
defined sign.

Examples:

```
call sign_define("mySign", {
        \ "text" : "=>",
        \ "texthl" : "Error",
        \ "linehl" : "Search"})
call sign_define([
        \ {'name' : 'sign1',
        \  'text' : '=>'},
        \ {'name' : 'sign2',
        \  'text' : '!!'}
        \ ])
```

Parameters:
- {list} (vim.fn.sign_define.dict[])

Return:
((0|-1)[])

sign_getdefined([{name}]) sign_getdefined()

Get a list of defined signs and their attributes.
This is similar to the :sign-list command.

If the {name} is not supplied, then a list of all the defined signs is returned. Otherwise the attribute of the specified sign is returned.

Each list item in the returned value is a dictionary with the following entries:

icon	full path to the bitmap file of the sign
linehl	highlight group used for the whole line the sign is placed in; not present if not set.
name	name of the sign
priority	default priority value of the sign
numhl	highlight group used for the line number where the sign is placed; not present if not set.
text	text that is displayed when there is no icon or the GUI is not being used.
texthl	highlight group used for the text item; not present if not set.
culhl	highlight group used for the text item when the cursor is on the same line as the sign and 'cursorline' is enabled; not present if not set.

Returns an empty List if there are no signs and when {name} is not found.

Examples:

```
" Get a list of all the defined signs
echo sign_getdefined()

" Get the attribute of the sign named mySign
echo sign_getdefined("mySign")
```

Parameters:
- {name} (string?)

Return:
(vim.fn.sign_getdefined.ret.item[])

sign_getplaced([{buf} [, {dict}]]) sign_getplaced()

Return a list of signs placed in a buffer or all the buffers.
This is similar to the :sign-place-list command.

If the optional buffer name {buf} is specified, then only the list of signs placed in that buffer is returned. For the use of {buf}, see bufname(). The optional {dict} can contain the following entries:

group	select only signs in this group
id	select sign with this identifier
lnum	select signs placed in this line. For the use of {lnum}, see line().

If {group} is "*", then signs in all the groups including the global group are returned. If {group} is not supplied or is an empty string, then only signs in the global group are returned. If no arguments are supplied, then signs in the global group placed in all the buffers are returned.
See sign-group.

Each list item in the returned value is a dictionary with the following entries:

bufnr	number of the buffer with the sign
signs	list of signs placed in {bufnr}. Each list item is a dictionary with the below listed entries

The dictionary for each sign contains the following entries:

group	sign group. Set to '' for the global group.
id	identifier of the sign
lnum	line number where the sign is placed
name	name of the defined sign
priority	sign priority

The returned signs in a buffer are ordered by their line number and priority.

Returns an empty list on failure or if there are no placed signs.

Examples:

```
" Get a List of signs placed in eval.c in the
" global group
echo sign_getplaced("eval.c")

" Get a List of signs in group 'g1' placed in eval.c
echo sign_getplaced("eval.c", {'group' : 'g1'})

" Get a List of signs placed at line 10 in eval.c
echo sign_getplaced("eval.c", {'lnum' : 10})

" Get sign with identifier 10 placed in a.py
echo sign_getplaced("a.py", {'id' : 10})

" Get sign with id 20 in group 'g1' placed in a.py
echo sign_getplaced("a.py", {'group' : 'g1',
                             \  'id' : 20})

" Get a List of all the placed signs
echo sign_getplaced()
```

Parameters:

- {buf} (integer|string?)
- {dict} (vim.fn.sign_getplaced.dict?)

Return:

(vim.fn.sign_getplaced.ret.item[])

sign_jump({id}, {group}, {buf}) sign_jump()

Open the buffer {buf} or jump to the window that contains {buf} and position the cursor at sign {id} in group {group}. This is similar to the :sign-jump command.

If {group} is an empty string, then the global group is used. For the use of {buf}, see bufname().

Returns the line number of the sign. Returns -1 if the arguments are invalid.

Example:

```
" Jump to sign 10 in the current buffer
call sign_jump(10, '', '')
```

Parameters:

- {id} (integer)
- {group} (string)
- {buf} (integer|string)

Return:

(integer)

sign_place({id}, {group}, {name}, {buf} [, {dict}]) sign_place()

Place the sign defined as {name} at line {lnum} in file or buffer {buf} and assign {id} and {group} to sign. This is similar to the :sign-place command.

If the sign identifier {id} is zero, then a new identifier is allocated. Otherwise the specified number is used. {group} is the sign group name. To use the global sign group, use an empty string. {group} functions as a namespace for {id}, thus two groups can use the same IDs. Refer to sign-identifier and sign-group for more information.

{name} refers to a defined sign.
{buf} refers to a buffer name or number. For the accepted values, see bufname().

The optional {dict} argument supports the following entries:

lnum	line number in the file or buffer {buf} where the sign is to be placed. For the accepted values, see line().
priority	priority of the sign. See sign-priority for more information.

If the optional {dict} is not specified, then it modifies the placed sign {id} in group {group} to use the defined sign {name}.

Returns the sign identifier on success and -1 on failure.

Examples:

```
" Place a sign named sign1 with id 5 at line 20 in
" buffer json.c
call sign_place(5, '', 'sign1', 'json.c',
                               \ {'lnum' : 20})

" Updates sign 5 in buffer json.c to use sign2
call sign_place(5, '', 'sign2', 'json.c')

" Place a sign named sign3 at line 30 in
" buffer json.c with a new identifier
let id = sign_place(0, '', 'sign3', 'json.c',
                               \ {'lnum' : 30})

" Place a sign named sign4 with id 10 in group 'g3'
" at line 40 in buffer json.c with priority 90
call sign_place(10, 'g3', 'sign4', 'json.c',
                \ {'lnum' : 40, 'priority' : 90})
```

Parameters:

- {id} (integer)
- {group} (string)
- {name} (string)
- {buf} (integer|string)
- {dict} (vim.fn.sign_place.dict?)

Return:

(integer)

sign_placelist({list}) sign_placelist()

Place one or more signs. This is similar to the sign_place() function. The {list} argument specifies the List of signs to place. Each list item is a dict with the following sign attributes:

buffer	Buffer name or number. For the accepted values, see bufname().
group	Sign group. {group} functions as a namespace for {id}, thus two groups can use the same IDs. If not specified or set to an empty string, then the global group is used. See sign-group for more information.
id	Sign identifier. If not specified or zero, then a new unique identifier is allocated. Otherwise the specified number is used. See sign-identifier for more information.
lnum	Line number in the buffer where the sign is to be placed. For the accepted values, see line().
name	Name of the sign to place. See sign_define() for more information.
priority	Priority of the sign. When multiple signs are placed on a line, the sign with the highest priority is used. If not specified, the default value of 10 is used, unless specified otherwise by the sign definition. See sign-priority for more information.

If {id} refers to an existing sign, then the existing sign is modified to use the specified {name} and/or {priority}.

Returns a List of sign identifiers. If failed to place a sign, the corresponding list item is set to -1.

Examples:

```
" Place sign s1 with id 5 at line 20 and id 10 at line
" 30 in buffer a.c
let [n1, n2] = sign_placelist([
        \ {'id' : 5,
        \  'name' : 's1',
        \  'buffer' : 'a.c',
        \  'lnum' : 20},
        \ {'id' : 10,
        \  'name' : 's1',
        \  'buffer' : 'a.c',
        \  'lnum' : 30}
        \ ])

" Place sign s1 in buffer a.c at line 40 and 50
" with auto-generated identifiers
let [n1, n2] = sign_placelist([
        \ {'name' : 's1',
        \  'buffer' : 'a.c',
        \  'lnum' : 40},
        \ {'name' : 's1',
        \  'buffer' : 'a.c',
        \  'lnum' : 50}
        \ ])
```

Parameters:
- {list} (vim.fn.sign_placelist.list.item[])

Return:
(integer[])

sign_undefine([{name}]) sign_undefine()

sign_undefine({list})
Deletes a previously defined sign {name}. This is similar to the :sign-undefine command. If {name} is not supplied, then deletes all the defined signs.

The one argument {list} can be used to undefine a list of signs. Each list item is the name of a sign.

Returns 0 on success and -1 on failure. For the one argument {list} call, returns a list of values one for each undefined sign.

Examples:

```
" Delete a sign named mySign
call sign_undefine("mySign")

" Delete signs 'sign1' and 'sign2'
call sign_undefine(["sign1", "sign2"])

" Delete all the signs
call sign_undefine()
```

Parameters:
- {list} (string[]?)

Return:
(integer[])

sign_unplace({group} [, {dict}]) sign_unplace()

Remove a previously placed sign in one or more buffers. This is similar to the :sign-unplace command.

{group} is the sign group name. To use the global sign group, use an empty string. If {group} is set to "*", then all the groups including the global group are used.
The signs in {group} are selected based on the entries in {dict}. The following optional entries in {dict} are supported:
        buffer buffer name or number. See bufname().
        id   sign identifier
If {dict} is not supplied, then all the signs in {group} are removed.

Returns 0 on success and -1 on failure.

Examples:

```
" Remove sign 10 from buffer a.vim
call sign_unplace('', {'buffer' : "a.vim", 'id' : 10})

" Remove sign 20 in group 'g1' from buffer 3
call sign_unplace('g1', {'buffer' : 3, 'id' : 20})

" Remove all the signs in group 'g2' from buffer 10
call sign_unplace('g2', {'buffer' : 10})

" Remove sign 30 in group 'g3' from all the buffers
call sign_unplace('g3', {'id' : 30})

" Remove all the signs placed in buffer 5
call sign_unplace('*', {'buffer' : 5})

" Remove the signs in group 'g4' from all the buffers
call sign_unplace('g4')

" Remove sign 40 from all the buffers
call sign_unplace('*', {'id' : 40})

" Remove all the placed signs from all the buffers
call sign_unplace('*')
```

Parameters:
- {group} (string)

- {dict} (vim.fn.sign_unplace.dict?)

Return:
(0|-1)

sign_unplacelist({list}) sign_unplacelist()

Remove previously placed signs from one or more buffers. This is similar to the sign_unplace() function.

The {list} argument specifies the List of signs to remove. Each list item is a dict with the following sign attributes:

buffer	buffer name or number. For the accepted values, see bufname(). If not specified, then the specified sign is removed from all the buffers.
group	sign group name. If not specified or set to an empty string, then the global sign group is used. If set to "*", then all the groups including the global group are used.
id	sign identifier. If not specified, then all the signs in the specified group are removed.

Returns a List where an entry is set to 0 if the corresponding sign was successfully removed or -1 on failure.

Example:

```
" Remove sign with id 10 from buffer a.vim and sign
" with id 20 from buffer b.vim
call sign_unplacelist([
        \ {'id' : 10, 'buffer' : "a.vim"},
        \ {'id' : 20, 'buffer' : 'b.vim'},
        \ ])
```

Parameters:
- {list} (vim.fn.sign_unplacelist.list.item)

Return:
((0|-1)[])

simplify({filename}) simplify()

Lua: Prefer vim.fs.normalize(); ~/$VAR expansion and leading ./ or trailing / handling differ.

Simplify the file name as much as possible without changing the meaning. Shortcuts (on MS-Windows) or symbolic links (on Unix) are not resolved. If the first path component in {filename} designates the current directory, this will be valid for the result as well. A trailing path separator is not removed either. On Unix "//path" is unchanged, but "///path" is simplified to "/path" (this follows the Posix standard).
Example:

```
simplify("./dir/.././/file/") == "./file/"
```

Note: The combination "dir/.." is only removed if "dir" is a searchable directory or does not exist. On Unix, it is also removed when "dir" is a symbolic link within the same

directory. In order to resolve all the involved symbolic
links before simplifying the path name, use resolve().

Parameters:
- {filename} (string)

Return:
(string)

sin({expr}) sin()

Lua: Prefer math.sin().

Return the sine of {expr}, measured in radians, as a Float.
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo sin(100)
```

-0.506366

```
echo sin(-4.01)
```

0.763301

Parameters:
- {expr} (number)

Return:
(number)

sinh({expr}) sinh()

Lua: Prefer math.sinh().

Return the hyperbolic sine of {expr} as a Float in the range
[-inf, inf].
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo sinh(0.5)
```

0.521095

```
echo sinh(-0.9)
```

-1.026517

Parameters:
- {expr} (number)

Return:
(any)

slice({expr}, {start} [, {end}]) slice()

Similar to using a slice "expr[start : end]", but "end" is
used exclusive. And for a string the indexes are used as
character indexes instead of byte indexes.
Also, composing characters are treated as a part of the
preceding base character.
When {end} is omitted the slice continues to the last item.
When {end} is -1 the last item is omitted.
Returns an empty value if {start} or {end} are invalid.

Parameters:
- {expr} (any)
- {start} (integer)
- {end} (integer?)

Return:
(any)

sockconnect({mode}, {address} [, {opts}]) sockconnect()

Connect a socket to an address. If {mode} is "pipe" then
{address} should be the path of a local domain socket (on
unix) or named pipe (on Windows). If {mode} is "tcp" then
{address} should be of the form "host:port" where the host
should be an ip address or host name, and port the port
number.

For "pipe" mode, see luv-pipe-handle. For "tcp" mode, see
luv-tcp-handle.

Returns a channel ID. Close the socket with chanclose(). Use chansend() to send data over a bytes socket, and rpcrequest() and rpcnotify() to communicate with a RPC socket.

{opts} is an optional dictionary with these keys:
  on_data : callback invoked when data was read from socket
  data_buffered : read socket data in channel-buffered mode.
  rpc   : If set, msgpack-rpc will be used to communicate
            over the socket.

Returns:

- The channel ID on success (greater than zero)
- 0 on invalid arguments or connection failure.

Parameters:

- {mode} (string)
- {address} (string)
- {opts} (table?)

Return:

(any)

sort({list} [, {how} [, {dict}]]) sort() E702

Lua: Prefer table.sort() with a custom comparator; it is not stable and Vim's i/`l`/`n`/`N`/`f` modes differ.

Sort the items in {list} in-place. Returns {list}.

If you want a list to remain unmodified make a copy first:

```
let sortedlist = sort(copy(mylist))
```

When {how} is omitted or is a string, then sort() uses the string representation of each item to sort on. Numbers sort after Strings, Lists after Numbers. For sorting text in the current buffer use :sort.

When {how} is given and it is 'i' then case is ignored. For backwards compatibility, the value one can be used to ignore case. Zero means to not ignore case.

When {how} is given and it is 'l' then the current collation locale is used for ordering. Implementation details: strcoll() is used to compare strings. See :language to check or set the collation locale. v:collate can also be used to check the current locale. Sorting using the locale typically ignores case. Example:

```
" ö is sorted similarly to o with English locale.
language collate en_US.UTF8
echo sort(['n', 'o', 'O', 'ö', 'p', 'z'], 'l')
```

['n', 'o', 'O', 'ö', 'p', 'z']

```
" ö is sorted after z with Swedish locale.
language collate sv_SE.UTF8
echo sort(['n', 'o', 'O', 'ö', 'p', 'z'], 'l')
```

['n', 'o', 'O', 'p', 'z', 'ö']

This does not work properly on Mac.

When {how} is given and it is 'n' then all items will be sorted numerical (Implementation detail: this uses the strtod() function to parse numbers, Strings, Lists, Dicts and Funcrefs will be considered as being 0).

When {how} is given and it is 'N' then all items will be sorted numerical. This is like 'n' but a string containing digits will be used as the number they represent.

When {how} is given and it is 'f' then all items will be sorted numerical. All values must be a Number or a Float.

When {how} is a Funcref or a function name, this function is called to compare items. The function is invoked with two items as argument and must return zero if they are equal, 1 or bigger if the first one sorts after the second one, -1 or smaller if the first one sorts before the second one.

{dict} is for functions with the "dict" attribute. It will be used to set the local variable "self". Dictionary-function

The sort is stable, items which compare equal (as number or as string) will keep their relative position. E.g., when sorting on numbers, text strings will sort next to each other, in the same order as they were originally.

Example:

```
func MyCompare(i1, i2)
   return a:i1 == a:i2 ? 0 : a:i1 > a:i2 ? 1 : -1
endfunc
eval mylist->sort("MyCompare")
```

A shorter compare version for this specific simple case, which ignores overflow:

```
func MyCompare(i1, i2)
   return a:i1 - a:i2
endfunc
```

For a simple expression you can use a lambda:

```
eval mylist->sort({i1, i2 -> i1 - i2})
```

Parameters:

- {list} (T[])
- {how} (string|function?)
- {dict} (any?)

Return:

(T[])

soundfold({word}) soundfold()

Return the sound-folded equivalent of {word}. Uses the first language in 'spelllang' for the current window that supports soundfolding. 'spell' must be set. When no sound folding is possible the {word} is returned unmodified.
This can be used for making spelling suggestions. Note that the method can be quite slow.

Parameters:

- {word} (string)

Return:

(string)

spellbadword([{sentence}]) spellbadword()

Lua: Prefer vim.spell.check() for string input; it returns all matches with positions, not just the first one or cursor-moving behavior.

Without argument: The result is the badly spelled word under or after the cursor. The cursor is moved to the start of the bad word. When no bad word is found in the cursor line the result is an empty string and the cursor doesn't move.

With argument: The result is the first word in {sentence} that is badly spelled. If there are no spelling mistakes the result is an empty string.

The return value is a list with two items:

- The badly spelled word or an empty string.
- The type of the spelling error:

```
"bad"           spelling mistake
"rare"          rare word
"local"         word only valid in another region
"caps"          word should start with Capital
```

Example:

```
echo spellbadword("the quik brown fox")
" ['quik', 'bad']
```

The spelling information for the current window and the value of 'spelllang' are used.

Parameters:

- {sentence} (string?)

Return:

(any)

spellsuggest({word} [, {max} [, {capital}]]) spellsuggest()

Return a List with spelling suggestions to replace {word}. When {max} is given up to this number of suggestions are returned. Otherwise up to 25 suggestions are returned.

When the {capital} argument is given and it's non-zero only suggestions with a leading capital will be given. Use this after a match with 'spellcapcheck'.

{word} can be a badly spelled word followed by other text. This allows for joining two words that were split. The suggestions also include the following text, thus you can replace a line.

{word} may also be a good word. Similar words will then be returned. {word} itself is not included in the suggestions, although it may appear capitalized.

The spelling information for the current window is used. The values of 'spelllang' and 'spellsuggest' are used.

Parameters:

- {word} (string)
- {max} (integer?)
- {capital} (boolean?)

Return:

(string[])

split({string} [, {pattern} [, {keepempty}]]) split()

Lua: Prefer vim.split().

Make a List out of {string}. When {pattern} is omitted or empty each white space separated sequence of characters becomes an item.
Otherwise the string is split where {pattern} matches, removing the matched characters. 'ignorecase' is not used here, add \c to ignore case. /\c
When the first or last item is empty it is omitted, unless the {keepempty} argument is given and it's non-zero.
Other empty items are kept when {pattern} matches at least one character or when {keepempty} is non-zero.
Example:

```
let words = split(getline('.'), '\W\+')
```

To split a string in individual characters:

```
for c in split(mystring, '\zs') | endfor
```

If you want to keep the separator you can also use '\zs' at the end of the pattern:

```
echo split('abc:def:ghi', ':\zs')
```

```
['abc:', 'def:', 'ghi']
```

Splitting a table where the first element can be empty:

```
let items = split(line, ':', 1)
```

The opposite function is join().

Parameters:

- {string} (string)
- {pattern} (string?)
- {keepempty} (boolean?)

Return:

(string[])

sqrt({expr}) sqrt()

Lua: Prefer math.sqrt().

Return the non-negative square root of Float {expr} as a Float.
{expr} must evaluate to a Float or a Number. When {expr} is negative the result is NaN (Not a Number). Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo sqrt(100)
```

```
10.0
```

```
echo sqrt(-4.01)
```

str2float("nan")
NaN may be different, it depends on system libraries.

Parameters:
- {expr} (number)

Return:
(any)

srand([{expr}]) srand()

Lua: Prefer math.randomseed().

Initialize seed used by rand():
- If {expr} is not given, seed values are initialized by

reading from /dev/urandom, if possible, or using time(NULL)
a.k.a. epoch time otherwise; this only has second accuracy.
- If {expr} is given it must be a Number. It is used to

initialize the seed values. This is useful for testing or
when a predictable sequence is intended.

Examples:

```
let seed = srand()
let seed = srand(userinput)
echo rand(seed)
```

Parameters:
- {expr} (number?)

Return:
(any)

state([{what}]) state()

Return a string which contains characters indicating the
current state. Mostly useful in callbacks that want to do
work that may not always be safe. Roughly this works like:
- callback uses state() to check if work is safe to do.

Yes: then do it right away.
No: add to work queue and add a SafeState autocommand.
- When SafeState is triggered and executes your autocommand,

check with state() if the work can be done now, and if yes
remove it from the queue and execute.
Remove the autocommand if the queue is now empty.
Also see mode().

When {what} is given only characters in this string will be
added. E.g, this checks if the screen has scrolled:

```
if state('s') == ''
   " screen has not scrolled
```

These characters indicate the state, generally indicating that
something is busy:
m halfway a mapping, :normal command, feedkeys() or
stuffed command
o operator pending, e.g. after d
a Insert mode autocomplete active
x executing an autocommand
S not triggering SafeState, e.g. after f or a count
c callback invoked, including timer (repeats for
recursiveness up to "ccc")
s screen has scrolled for messages

Attributes:
api-fast

Parameters:
- {what} (string?)

Return:
(any)

stdioopen({opts}) stdioopen()

With --headless this opens stdin and stdout as a channel.
May be called only once. See channel-stdio. stderr is not
handled by this function, see v:stderr.

Close the stdio handles with chanclose(). Use chansend()
to send data to stdout, and rpcrequest() and rpcnotify()
to communicate over RPC.

{opts} is a dictionary with these keys:
on_stdin : callback invoked when stdin is written to.
on_print : callback invoked when Nvim needs to print a
message, with the message (whose type is string)
as sole argument.
stdin_buffered : read stdin in channel-buffered mode.
rpc : If set, msgpack-rpc will be used to communicate
over stdio
Returns:

- channel-id on success (value is always 1)
- 0 on invalid arguments

Parameters:

- {opts} (table)

Return:

(any)

stdpath({what}) stdpath() E6100

Returns standard-path locations of various default files and directories. The locations are driven by base-directories which you can configure via $NVIM_APPNAME or the $XDG_… environment variables.

{what}	Type	Description
cache	String	Cache directory: arbitrary temporary storage for plugins, etc.
config	String	User configuration directory. init.vim is stored here.
config_dirs	List	Other configuration directories.
data	String	User data directory.
data_dirs	List	Other data directories.
log	String	Logs directory (for use by plugins too).
run	String	Run directory: temporary, local storage for sockets, named pipes, etc.
state	String	Session state: storage for backupdir, file drafts, shada, swap, undo, 'viewdir'.

Example:

```
echo stdpath("config")
```

Attributes:

api-fast

Parameters:

- {what}

('cache'|'config'|'config_dirs'|'data'|'data_dirs'|'log'|'run'|'state')

Return:

(string|string[])

str2float({string} [, {quoted}]) str2float()

Lua: Prefer tonumber() for simple numbers; quoted digits, hex forms, and trailing text differ.

Convert String {string} to a Float. This mostly works the same as when using a floating point number in an expression, see floating-point-format. But it's a bit more permissive. E.g., "1e40" is accepted, while in an expression you need to write "1.0e40". The hexadecimal form "0x123" is also accepted, but not others, like binary or octal.
When {quoted} is present and non-zero then embedded single quotes before the dot are ignored, thus "1'000.0" is a thousand.
Text after the number is silently ignored.
The decimal point is always '.', no matter what the locale is set to. A comma ends the number: "12,345.67" is converted to 12.0. You can strip out thousands separators with substitute():

```
let f = str2float(substitute(text, ',', '', 'g'))
```

Returns 0.0 if the conversion fails.

Parameters:

- {string} (string)
- {quoted} (boolean?)

Return:

(any)

str2list({string} [, {utf8}]) str2list()

Return a list containing the number values which represent
each character in String {string}. Examples:

```
echo str2list(" ")              " returns [32]
echo str2list("ABC")            " returns [65, 66, 67]
```

list2str() does the opposite.

UTF-8 encoding is always used, {utf8} option has no effect,
and exists only for backwards-compatibility.
With UTF-8 composing characters are handled properly:

```
echo str2list("á")              " returns [97, 769]
```

Attributes:
api-fast

Parameters:
- {string} (string)

- {utf8} (boolean?)

Return:
(any)

str2nr({string} [, {base}]) str2nr()

Lua: Prefer tonumber() for simple numbers; quoted digits,
base prefixes, and trailing text differ.

Convert string {string} to a number.
{base} is the conversion base, it can be 2, 8, 10 or 16.
When {quoted} is present and non-zero then embedded single
quotes are ignored, thus "1'000'000" is a million.

When {base} is omitted base 10 is used. This also means that
a leading zero doesn't cause octal conversion to be used, as
with the default String to Number conversion. Example:

```
let nr = str2nr('0123')
```

When {base} is 16 a leading "0x" or "0X" is ignored. With a
different base the result will be zero. Similarly, when
{base} is 8 a leading "0", "0o" or "0O" is ignored, and when
{base} is 2 a leading "0b" or "0B" is ignored.
Text after the number is silently ignored.

Returns 0 if {string} is empty or on error.

Parameters:
- {string} (string)

- {base} (integer?)

Return:
(any)

strcharlen({string}) strcharlen()

Returns the number of characters in String {string}, ignoring
composing characters. Returns 0 on error or empty {string}.

strchars() can count the number of characters, counting
composing characters separately.

Also see strlen(), strdisplaywidth() and strwidth().

Attributes:
api-fast

Parameters:
- {string} (string)

Return:
(integer)

strcharpart({src}, {start} [, {len} [, {skipcc}]]) strcharpart()

Like strpart() but using character index and length instead
of byte index and length.
When {skipcc} is omitted or zero, composing characters are
counted separately.
When {skipcc} set to 1, composing characters are treated as a
part of the preceding base character, similar to slice().
When a character index is used where a character does not
exist it is omitted and counted as one character. For
example:

```
echo strcharpart('abc', -1, 2)
```

results in 'a'.

Returns an empty string on error.

Attributes:

api-fast

Parameters:

- {src} (string)
- {start} (integer)
- {len} (integer?)
- {skipcc} (0|1|boolean?)

Return:

(string)

strchars({string} [, {skipcc}]) strchars()

Lua: Prefer vim.str_utfindex() for codepoint counts;
skipcc handling differs.

Returns the number of characters in String {string}.
When {skipcc} is omitted or zero, composing characters are
counted separately.
When {skipcc} set to 1, composing characters are ignored.
strcharlen() always does this.

Returns zero on error.

Also see strlen(), strdisplaywidth() and strwidth().

{skipcc} is only available after 7.4.755. For backward
compatibility, you can define a wrapper function:

```
if has("patch-7.4.755")
  function s:strchars(str, skipcc)
    return strchars(a:str, a:skipcc)
  endfunction
else
  function s:strchars(str, skipcc)
    if a:skipcc
      return strlen(substitute(a:str, ".", "x", "g"))
    else
      return strchars(a:str)
    endif
  endfunction
endif
```

Attributes:

api-fast

Parameters:

- {string} (string)
- {skipcc} (0|1|boolean?)

Return:

(integer)

strdisplaywidth({string} [, {col}]) strdisplaywidth()

Lua: Prefer nvim_strwidth() when {col} is 0; Tab expansion
and window-option semantics differ.

Returns the number of display cells String {string} occupies
on the screen when it starts at {col} (first column is zero).
Returns zero on error.

When {col} is omitted zero is used. Otherwise it is the screen
column where to start. This matters for Tab characters.
The option settings of the current window are used. This
matters for anything that's displayed differently, such as
'tabstop' and 'display'.

When {string} contains characters with East Asian Width Class
Ambiguous, this function's return value depends on
'ambiwidth'.

Also see strlen(), strwidth() and strchars().

Attributes:

api-fast

Parameters:

- {string} (string)
- {col} (integer?)

Return:
(integer)

strftime({format} [, {time}]) strftime()

Lua: Prefer os.date().

Formats a date and time String specified by {format}. The
given {time} is used, or the current time if no time is given.
The {format} depends on your system, this is not portable!
See the manual page of the C function strftime() for the
format. The maximum length of the result is 80 characters.
See also localtime(), getftime() and strptime().
The language can be changed with the :language command.
Examples:

```
echo strftime("%c")                " Sun Apr 27 11:49:23 1997
echo strftime("%Y %b %d %X")       " 1997 Apr 27 11:53:25
echo strftime("%y%m%d %T")         " 970427 11:53:55
echo strftime("%H:%M")             " 11:55
echo strftime("%c", getftime("file.c"))
                                 " Show mod time of file.c.
```

Parameters:
- {format} (string)

- {time} (number?)

Return:
(string)

strgetchar({str}, {index}) strgetchar()

Get a Number corresponding to the character at {index} in
{str}. This uses a zero-based character index, not a byte
index. Composing characters are considered separate
characters here. Use nr2char() to convert the Number to a
String.
Returns -1 if {index} is invalid.
Also see strcharpart() and strchars().

Attributes:
api-fast

Parameters:
- {str} (string)

- {index} (integer)

Return:
(integer)

stridx({haystack}, {needle} [, {start}]) stridx()

Lua: Prefer string.find() with plain = true and
start + 1, then subtract 1; missing matches return nil
instead of -1.

Returns the byte index of the first occurrence of {needle}
in {haystack}.
If {start} is specified, the search starts at index {start}.
This can be used to find a second match:

```
let colon1 = stridx(line, ":")
let colon2 = stridx(line, ":", colon1 + 1)
```

The search is done case-sensitive.
For pattern searches use match().
-1 is returned if the {needle} does not occur in {haystack}.
See also strridx().
Examples:

```
echo stridx("An Example", "Example")     " 3
echo stridx("Starting point", "Start")   " 0
echo stridx("Starting point", "start")   " -1
```

strstr() strchr()
stridx() works similar to the C function strstr(). When used
with a single character it works similar to strchr().

Attributes:
api-fast

Parameters:
- {haystack} (string)

- {needle} (string)

- {start} (integer?)

Return:
(integer)

`string({expr})` string()

Lua: Prefer vim.inspect() for tables, or tostring() for scalars.

Converts {expr} to a String. If {expr} is a Number, Float, String, Blob or a composition of them, the result can be parsed back with eval().

{expr} type	result
String	'string'
Number	123
Float	123.123456 or 1.123456e8 or str2float('inf')
Funcref	function('name')
Blob	0z00112233.44556677.8899
List	[item, item]
Dictionary	{key: value, key: value}

Note: in String values the ' character is doubled.
Also see strtrans().

Note: Output format is mostly compatible with YAML, except for infinite and NaN floating-point values representations which use str2float(). Strings are also dumped literally, only single quote is escaped, which does not allow using YAML for parsing back binary strings. eval() should always work for strings and floats though, and this is the only official method. Use msgpackdump() or json_encode() if you need to share data with other applications.

Parameters:
- {expr} (any)

Return:
(string)

`strlen({string})` strlen()

Lua: Prefer string.len().

Returns the length of String {string} in bytes.
If the argument is a Number it is first converted to a String.
For other types an error is given and zero is returned.
If you want to count the number of multibyte characters use strchars().
Also see len(), strdisplaywidth() and strwidth().

Attributes:
api-fast

Parameters:
- {string} (string)

Return:
(integer)

`strpart({src}, {start} [, {len} [, {chars}]])` strpart()

Lua: Prefer string.sub() for byte slices; negative start and the chars flag differ.

Gets a substring from {src}, starting from byte {start}, with byte length {len}. Returns empty string on error.

When {chars} is present and TRUE then {len} is the number of characters positions (composing characters are not counted separately, thus "1" means one base character and any following composing characters).

To count {start} as characters instead of bytes use strcharpart().

When bytes are selected which do not exist, this doesn't result in an error, the bytes are simply omitted.
If {len} is missing, the copy continues from {start} till the end of the {src}.

```
echo strpart("abcdefg", 3, 2)    " returns 'de'
echo strpart("abcdefg", -2, 4)   " returns 'ab'
echo strpart("abcdefg", 5, 4)    " returns 'fg'
echo strpart("abcdefg", 3)       " returns 'defg'
```

Note: To get the first character, {start} must be 0. For example, to get the character under the cursor:

```
strpart(getline("."), col(".") - 1, 1, v:true)
```

Attributes:
api-fast

Parameters:
- {src} (string)
- {start} (integer)
- {len} (integer?)
- {chars} (0|1?)

Return:
(string)

strptime({format}, {timestring}) strptime()

Parses a date/time string and returns a unix timestamp.
{timestring} must match the format specified in {format}.

The {format} depends on your system, this is not portable!
See the strptime() manpage for the format. Especially avoid
"%c". The value of $TZ also matters.

If the {timestring} cannot be parsed with {format} zero is
returned. If you do not know the format of {timestring} you
can try different {format} values until you get a non-zero
result.

See also strftime().
Examples:

```
echo strptime("%Y %b %d %X", "1997 Apr 27 11:49:23")
```

862156163

```
echo strftime("%c", strptime("%y%m%d %T", "970427 11:53:55"))
```

Sun Apr 27 11:53:55 1997

```
echo strftime("%c", strptime("%Y%m%d%H%M%S", "19970427115355") + 3600)
```

Sun Apr 27 12:53:55 1997

Parameters:
- {format} (string)
- {timestring} (string)

Return:
(integer)

strridx({haystack}, {needle} [, {start}]) strridx()

Lua: Prefer string.find() in a loop with plain = true,
then subtract 1; empty-needle and missing-match semantics
differ.

Returns the byte index of the last occurrence of {needle}
in {haystack}.
When {start} is specified, matches beyond this index are
ignored. This can be used to find a match before a previous
match:

```
let lastcomma = strridx(line, ",")
let comma2 = strridx(line, ",", lastcomma - 1)
```

The search is done case-sensitive.
For pattern searches use match().
-1 is returned if the {needle} does not occur in {haystack}.
If the {needle} is empty the length of {haystack} is returned.
See also stridx(). Examples:

```
echo strridx("an angry armadillo", "an")            3
```

strrchr()

When used with a single character it works similar to the C
function strrchr().

Parameters:
- {haystack} (string)
- {needle} (string)

- {start} (integer?)

Return:
(integer)

strtrans({string}) strtrans()

Translates all unprintable characters in {string} into
printable characters, like they are shown in a
window. Example:

```
echo strtrans(@a)
```

This displays a newline in register a as "^@" instead of
starting a new line.

Returns an empty string on error.

Attributes:
api-fast

Parameters:
- {string} (string)

Return:
(string)

strutf16len({string} [, {countcc}]) strutf16len()

Lua: Prefer vim.str_utfindex() with "utf-16";
countcc = false semantics differ.

Returns the number of UTF-16 code units in String {string}
(after converting it to UTF-16).

When {countcc} is TRUE, composing characters are counted
separately.
When {countcc} is omitted or FALSE, composing characters are
ignored.

Returns zero on error.

Also see strlen() and strcharlen().
Examples:

```
echo strutf16len('a')           " returns 1
echo strutf16len('©')           " returns 1
echo strutf16len('😊')          " returns 2
echo strutf16len('á')           " returns 1
echo strutf16len('á', v:true)   " returns 3
```

Parameters:
- {string} (string)

- {countcc} (0|1?)

Return:
(integer)

strwidth({string}) strwidth()

Lua: Prefer nvim_strwidth().

Returns the number of display cells String {string} occupies.
A Tab character is counted as one cell, alternatively use
strdisplaywidth().
When {string} contains characters with East Asian Width Class
Ambiguous, this function's return value depends on
'ambiwidth'.
Returns zero on error.
Also see strlen(), strdisplaywidth() and strchars().

Attributes:
api-fast

Parameters:
- {string} (string)

Return:
(integer)

submatch({nr} [, {list}]) submatch() E935
Only for an expression in a :substitute command or
substitute() function.
Returns the {nr}th submatch of the matched text. When {nr}
is 0 the whole matched text is returned.
Note that a NL in the string can stand for a line break of a
multi-line match or a NUL character in the text.
Also see sub-replace-expression.

If {list} is present and non-zero then submatch() returns
a list of strings, similar to getline() with two arguments.
NL characters in the text represent NUL characters in the
text.
Only returns more than one item for :substitute, inside
substitute() this list will always contain one or zero
items, since there are no real line breaks.

When substitute() is used recursively only the submatches in
the current (deepest) call can be obtained.

Returns an empty string or list on error.

Examples:

```
s/\d\+/\=submatch(0) + 1/
echo substitute(text, '\d\+', '\=submatch(0) + 1', '')
```

This finds the first number in the line and adds one to it.
A line break is included as a newline character.

Parameters:

- {nr} (integer)

- {list} (nil?)

Return:

(string)

substitute({string}, {pat}, {sub}, {flags}) substitute()

Lua: Prefer string.gsub() for common substitutions; Vim
patterns, flags, and replacement semantics differ.

Performs string substitution. Returns a copy of {string}
in which the first match of {pat} is replaced with {sub}.
When {flags} is "g", all matches of {pat} in {string} are
replaced. Otherwise {flags} should be "".

This works like the ":substitute" command (without any flags).
But the matching with {pat} is always done like the 'magic'
option is set and 'cpoptions' is empty (to make scripts
portable). 'ignorecase' is still relevant, use /\c or /\C
if you want to ignore or match case and ignore 'ignorecase'.
'smartcase' is not used. See string-match for how {pat} is
used.

A "~" in {sub} is not replaced with the previous {sub}.
Note that some codes in {sub} have a special meaning
sub-replace-special. For example, to replace something with
"\n" (two characters), use "\\\n" or '\\n'.

When {pat} does not match in {string}, {string} is returned
unmodified.

Example:

```
let &path = substitute(&path, ",\\=[^,]*$", "", "")
```

This removes the last component of the 'path' option.

```
echo substitute("testing", ".*", "\\U\\0", "")
```

results in "TESTING".

When {sub} starts with "\=", the remainder is interpreted as
an expression. See sub-replace-expression. Example:

```
echo substitute(s, '%\(\x\x\)',
   \ '\=nr2char("0x" .. submatch(1))', 'g')
```

When {sub} is a Funcref that function is called, with one
optional argument. Example:

```
echo substitute(s, '%\(\x\x\)', SubNr, 'g')
```

The optional argument is a list which contains the whole
matched string and up to nine submatches, like what
submatch() returns. Example:

```
echo substitute(s, '%\(\x\x\)', {m -> '0x' .. m[1]}, 'g')
```

Returns an empty string on error.

Parameters:

- {string} (string)

- {pat} (string)

- {sub} (string)

- {flags} (string)

Return:
(string)

swapfilelist() swapfilelist()

Returns a list of swap file names, like what "vim -r" shows.
See the -r command argument. The 'directory' option is used
for the directories to inspect. If you only want to get a
list of swap files in the current directory then temporarily
set 'directory' to a dot:

```
let save_dir = &directory
let &directory = '.'
let swapfiles = swapfilelist()
let &directory = save_dir
```

Return:
(string[])

swapinfo({fname}) swapinfo()

Returns information about the swapfile {fname} as a
dictionary. The available fields are:
version Vim version
user user name
host host name
fname original file name
pid PID of the Nvim process that created the swap
file, or zero if not running.
mtime last modification time in seconds
inode Optional: INODE number of the file
dirty 1 if file was modified, 0 if not
In case of failure an "error" item is added with the reason:
Cannot open file: file not found or in accessible
Cannot read file: cannot read first block
Not a swap file: does not contain correct block ID
Magic number mismatch: Info in first block is invalid

Parameters:
- {fname} (string)

Return:
(any)

swapname({buf}) swapname()

The result is the swap file path of the buffer {buf}.
For the use of {buf}, see bufname() above.
If buffer {buf} is the current buffer, the result is equal to
:swapname (unless there is no swap file).
If buffer {buf} has no swap file, returns an empty string.

Parameters:
- {buf} (integer|string)

Return:
(string)

synID({lnum}, {col}, {trans}) synID()

Returns the syntax ID at position {lnum} and {col} in the
current window. The syntax ID can be used with synIDattr()
and synIDtrans() to obtain syntax information about text.

{col} is 1 for the leftmost column, {lnum} is 1 for the first
line. 'synmaxcol' applies, in a longer line zero is returned.
Note that when the position is after the last character,
that's where the cursor can be in Insert mode, synID() returns
zero. {lnum} is used like with getline().

When {trans} is TRUE, transparent items are reduced to the
item that they reveal. This is useful when wanting to know
the effective color. When {trans} is FALSE, the transparent
item is returned. This is useful when wanting to know which
syntax item is effective (e.g. inside parens).
Warning: This function can be very slow. Best speed is
obtained by going through the file in forward direction.

Returns zero on error.

Example (echoes the name of the syntax item under the cursor):

```
echo synIDattr(synID(line("."), col("."), 1), "name")
```

Parameters:
- {lnum} (integer|string)

- {col} (integer)

- {trans} (0|1)

Return:
(integer)

synIDattr({synID}, {what} [, {mode}]) synIDattr()

Returns the {what} attribute of syntax ID {synID} as a
String. This can be used to obtain information about a
syntax item.
{mode} can be "gui" or "cterm", to get the attributes
for that mode. When {mode} is omitted, or an invalid value is
used, the attributes for the currently active highlighting are
used (GUI or cterm).
Use synIDtrans() to follow linked highlight groups.

{what}	result
"name"	the name of the syntax item
"fg"	foreground color (GUI: color name used to set the color, cterm: color number as a string, term: empty string)
"bg"	background color (as with "fg")
"font"	font name (only available in the GUI) highlight-font
"sp"	special color (as with "fg") guisp
"fg#"	like "fg", but for the GUI and the GUI is running the name in "#RRGGBB" form
"bg#"	like "fg#" for "bg"
"sp#"	like "fg#" for "sp"
"bold"	"1" if bold
"italic"	"1" if italic
"reverse"	"1" if reverse
"inverse"	"1" if inverse (= reverse)
"standout"	"1" if standout
"underline"	"1" if underlined
"undercurl"	"1" if undercurled
"underdouble"	"1" if double underlined
"underdotted"	"1" if dotted underlined
"underdashed"	"1" if dashed underlined
"strikethrough"	"1" if struckthrough
"altfont"	"1" if alternative font
"nocombine"	"1" if nocombine
"dim"	"1" if half-bright/dimmed
"blink"	"1" if blinking
"conceal"	"1" if concealed
"overline"	"1" if overlined

Returns an empty string on error.

Example (echoes the color of the syntax item under the
cursor):

```
echo synIDattr(synIDtrans(synID(line("."), col("."), 1)), "fg")
```

Can also be used as a method:

```
echo synID(line("."), col("."), 1)->synIDtrans()->synIDattr("fg")
```

Parameters:
- {synID} (integer)

- {what} (string)

- {mode} (string?)

Return:
(string)

synIDtrans({synID}) synIDtrans()

Returns the translated syntax ID of {synID}, following
highlight links. This is the syntax group ID of what is
being used to highlight the character. Highlight links given with
":highlight link" are followed.

Returns zero on error.

Parameters:
- {synID} (integer)

Return:
(integer)

synconcealed({lnum}, {col}) synconcealed()

Returns conceal information for the character at position {lnum} and {col} as a List with three items:

1. The first item in the list is 0 if the character is not part of a concealable region, 1 if it is. {lnum} is used like with getline().
2. The second item in the list is a string. If the first item is 1, the second item contains the text which will be displayed in place of the concealed text, depending on the current setting of 'conceallevel' and 'listchars'.
3. The third and final item in the list is a number representing the specific syntax region matched in the line. When the character is not concealed the value is zero. This allows detection of the beginning of a new concealable region if there are two consecutive regions with the same replacement character. For an example, if the text is "123456" and both "23" and "45" are concealed and replaced by the character "X", then:

call	returns ~
synconcealed(lnum, 1)	[0, '', 0]
synconcealed(lnum, 2)	[1, 'X', 1]
synconcealed(lnum, 3)	[1, 'X', 1]
synconcealed(lnum, 4)	[1, 'X', 2]
synconcealed(lnum, 5)	[1, 'X', 2]
synconcealed(lnum, 6)	[0, '', 0]

Note: Doesn't consider matchadd() highlighting items, since syntax and matching highlighting are two different mechanisms syntax-vs-match.

Parameters:

- {lnum} (integer|string)
- {col} (integer)

Return:

([integer, string, integer])

synstack({lnum}, {col}) synstack()

Return a List, which is the stack of syntax items at the position {lnum} and {col} in the current window. {lnum} is used like with getline(). Each item in the List is an ID like what synID() returns.
The first item in the List is the outer region, following are items contained in that one. The last one is what synID() returns, unless not the whole item is highlighted or it is a transparent item.
This function is useful for debugging a syntax file.
Example that shows the syntax stack under the cursor:

```
for id in synstack(line("."), col("."))
   echo synIDattr(id, "name")
endfor
```

When the position specified with {lnum} and {col} is invalid an empty list is returned. The position just after the last character in a line and the first column in an empty line are valid positions.

Parameters:

- {lnum} (integer|string)
- {col} (integer)

Return:

(integer[])

system({cmd} [, {input}]) system() E677

Lua: Prefer vim.system(...):wait().stdout for string output; string commands use the shell in Vimscript, not by default in Lua.

Gets the output of {cmd} as a string (systemlist() returns a List) and sets v:shell_error to the error code.
{cmd} is treated as in jobstart():
If {cmd} is a List it runs directly (no 'shell').
If {cmd} is a String it runs in the 'shell', like this:

```
call jobstart(split(&shell) + split(&shellcmdflag) + ['{cmd}'])
```

Not to be used for interactive commands.

Result is a String, filtered to avoid platform-specific quirks:

- <CR><NL> is replaced with <NL>

- NUL characters are replaced with SOH (0x01)

Example:

```
echo system(['ls', expand('%:h')])
```

If {input} is a string it is written to a pipe and passed as stdin to the command. The string is written as-is, line separators are not changed.
If {input} is a List it is written to the pipe as writefile() does with {binary} set to "b" (i.e. with a newline between each list item, and newlines inside list items converted to NULs).
When {input} is given and is a valid buffer id, the content of the buffer is written to the file line by line, each line terminated by NL (and NUL where the text has NL).

E5677

Note: system() cannot write to or read from backgrounded ("&") shell commands, e.g.:

```
echo system("cat - &", "foo")
```

which is equivalent to:

```
$ echo foo | bash -c 'cat - &'
```

The pipes are disconnected (unless overridden by shell redirection syntax) before input can reach it. Use jobstart() instead.

Note: Use shellescape() or ::S with expand() or fnamemodify() to escape special characters in a command argument. 'shellquote' and 'shellxquote' must be properly configured. Example:

```
echo system('ls '..shellescape(expand('%:h')))
echo system('ls '..expand('%:h:S'))
```

Unlike ":!cmd" there is no automatic check for changed files. Use :checktime to force a check.

Parameters:
- {cmd} (string|string[])

- {input} (string|string[]|integer?)

Return:
(string)

systemlist({cmd} [, {input} [, {keepempty}]]) systemlist()

Lua: Prefer vim.system(...):wait().stdout split into lines; string commands use the shell in Vimscript, not by default in Lua.

Same as system(), but returns a List with lines (parts of output separated by NL) with NULs transformed into NLs. Output is the same as readfile() will output with {binary} argument set to "b", except that a final newline is not preserved, unless {keepempty} is non-zero.
Note that on MS-Windows you may get trailing CR characters.

To see the difference between "echo hello" and "echo -n hello" use system() and split():

```
echo split(system('echo hello'), '\n', 1)
```

Returns an empty string on error.

Parameters:
- {cmd} (string|string[])

- {input} (string|string[]|integer?)

- {keepempty} (integer?)

Return:
(string[])

tabpagebuflist([{arg}]) tabpagebuflist()

Lua: Prefer nvim_tabpage_list_wins() with

nvim_win_get_buf(); invalid tabpages error instead of
returning 0.

Returns a List of buffer numbers, one for each window in
the specified tabpage.
{arg} specifies the number of the tabpage to be used. When
omitted the current tabpage is used.
When {arg} is invalid the number zero is returned.
To get a list of all buffers in all tabs use this:

```
let buflist = []
for i in range(tabpagenr('$'))
   call extend(buflist, tabpagebuflist(i + 1))
endfor
```

Note that a buffer may appear in more than one window.

Parameters:
- {arg} (integer?)

Return:
(any)

tabpagenr([{arg}]) tabpagenr()

Lua: Prefer nvim_tabpage_get_number() with
nvim_get_current_tabpage() for the current tab, or
#vim.api.nvim_list_tabpages() for "$"; "#" differs.

Returns the current tabpage-number.

The optional argument {arg} supports the following values:
  $ the last tabpage-number (the tabpage count).
  #   the last-accessed tabpage-number (where g<Tab>
        goes to), or 0 if there is no previous tabpage.
The number can be used with the :tab command.

Returns zero on error.

Parameters:
- {arg} ('$'|'#'?)

Return:
(integer)

tabpagewinnr({tabarg} [, {arg}]) tabpagewinnr()

Lua: Prefer nvim_win_get_number() with
nvim_tabpage_get_win() for the current window, or the length
of nvim_tabpage_list_wins() for "$"; "#" and invalid-tab
behavior differ.

Like winnr() but for tabpage {tabarg}.
{tabarg} specifies the tabpage-number to be used.
{arg} is used like with winnr():
- When omitted the current window number is returned. This is
  the window which will be used when going to this tabpage.
- When "$" the number of windows is returned.
- When "#" the previous window nr is returned.

Useful examples:

```
tabpagewinnr(1)     " current window of tabpage 1
tabpagewinnr(4, '$')    " number of windows in tabpage 4
```

When {tabarg} is invalid zero is returned.

Parameters:
- {tabarg} (integer)
- {arg} ('$'|'#'?)

Return:
(integer)

tagfiles() tagfiles()

Returns a List with the file names used to search for tags
for the current buffer. This is the 'tags' option expanded.

Return:
(string[])

taglist({expr} [, {filename}]) taglist()

Returns a List of tags matching the regular expression {expr}.

If {filename} is passed it is used to prioritize the results in the same way that :tselect does. See tag-priority. {filename} should be the full path of the file.

Each list item is a dictionary with at least the following entries:

name	Name of the tag.
filename	Name of the file where the tag is defined. It is either relative to the current directory or a full path.
cmd	Ex command used to locate the tag in the file.
kind	Type of the tag. The value for this entry depends on the language specific kind values. Only available when using a tags file generated by Universal/Exuberant ctags or hdrtag.
static	A file specific tag. Refer to static-tag for more information.

More entries may be present, depending on the content of the tags file: access, implementation, inherits and signature. Refer to the ctags documentation for information about these fields. For C code the fields "struct", "class" and "enum" may appear, they give the name of the entity the tag is contained in.

The ex-command "cmd" can be either an ex search pattern, a line number or a line number followed by a byte number.

If there are no matching tags, then an empty list is returned.

To get an exact tag match, the anchors '^' and '$' should be used in {expr}. This also make the function work faster. Refer to tag-regexp for more information about the tag search regular expression pattern.

Refer to 'tags' for information about how the tags file is located by Vim. Refer to tags-file-format for the format of the tags file generated by the different ctags tools.

Parameters:

- {expr} (any)
- {filename} (string?)

Return:

(any)

tan({expr}) tan()

Lua: Prefer math.tan().

Return the tangent of {expr}, measured in radians, as a Float in the range [-inf, inf].
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo tan(10)
```

```
0.648361
```

```
echo tan(-4.01)
```

```
-1.181502
```

Parameters:

- {expr} (number)

Return:

(number)

tanh({expr}) tanh()

Lua: Prefer math.tanh().

Return the hyperbolic tangent of {expr} as a Float in the range [-1, 1].
{expr} must evaluate to a Float or a Number.
Returns 0.0 if {expr} is not a Float or a Number.
Examples:

```
echo tanh(0.5)
```

```
0.462117
```

```
echo tanh(-1)
```

```
-0.761594
```

Parameters:

- {expr} (number)

Return:
(number)

tempname() tempname()

Lua: Prefer os.tmpname() for a temporary name; Nvim's tempdir and nonexistence are not guaranteed.

Generates a (non-existent) filename located in the Nvim root tempdir. Scripts can use the filename as a temporary file. Example:

```
let tmpfile = tempname()
exe "redir > " .. tmpfile
```

Return:
(string)

test_garbagecollect_now() test_garbagecollect_now()

Like garbagecollect(), but executed right away. This must only be called directly to avoid any structure to exist internally, and v:testing must have been set before calling any function. E1142

Return:
(any)

timer_info([{id}]) timer_info()

Return a list with information about timers.
When {id} is given only information about this timer is returned. When timer {id} does not exist an empty list is returned.
When {id} is omitted information about all timers is returned.

For each timer the information is stored in a Dictionary with these items:

"id"	the timer ID
"time"	time the timer was started with
"repeat"	number of times the timer will still fire; -1 means forever
"callback"	the callback

Parameters:
- {id} (integer?)

Return:
(any)

timer_pause({timer}, {paused}) timer_pause()

Pause or unpause a timer. A paused timer does not invoke its callback when its time expires. Unpausing a timer may cause the callback to be invoked almost immediately if enough time has passed.

Pausing a timer is useful to avoid the callback to be called for a short time.

If {paused} evaluates to a non-zero Number or a non-empty String, then the timer is paused, otherwise it is unpaused. See non-zero-arg.

Parameters:
- {timer} (integer)
- {paused} (boolean)

Return:
(any)

timer_start({time}, {callback} [, {options}]) timer_start() timer

Lua: Prefer vim.defer_fn() for one-shot timers, or uv.new_timer() for repeating timers; callback and handle semantics differ.

Create a timer and return the timer ID.

{time} is the waiting time in milliseconds. This is the minimum time before invoking the callback. When the system is busy or Vim is not waiting for input the time will be longer. Zero can be used to execute the callback when Vim is back in the main loop.

{callback} is the function to call. It can be the name of a function or a Funcref. It is called with one argument, which is the timer ID. The callback is only invoked when Vim is waiting for input.

{options} is a dictionary. Supported entries:

"repeat"	Number of times to repeat the callback. -1 means forever. Default is 1.

If the timer causes an error three times in a row the repeat is cancelled.

Returns -1 on error.

Example:

```
func MyHandler(timer)
  echo 'Handler called'
endfunc
let timer = timer_start(500, 'MyHandler',
        \ {'repeat': 3})
```

This invokes MyHandler() three times at 500 msec intervals.

Parameters:
- {time} (number)
- {callback} (string|function)
- {options} (table?)

Return:
(any)

timer_stop({timer}) timer_stop()

Lua: Prefer uv.timer_stop() and uv.close() on a stored uv.new_timer() handle; timer IDs differ.

Stop a timer. The timer callback will no longer be invoked. {timer} is an ID returned by timer_start(), thus it must be a Number. If {timer} does not exist there is no error.

Parameters:
- {timer} (integer)

Return:
(any)

timer_stopall() timer_stopall()

Stop all timers. The timer callbacks will no longer be invoked. Useful if some timers is misbehaving. If there are no timers there is no error.

Return:
(any)

tolower({expr}) tolower()

Lua: Prefer string.lower().

Converts a String to lowercase (like applying gu). Returns empty string on error.

Attributes:
api-fast

Parameters:
- {expr} (string)

Return:
(string)

toupper({expr}) toupper()

Lua: Prefer string.upper().

Converts a String to uppercase (like applying gU). Returns empty string on error.

Attributes:
api-fast

Parameters:
- {expr} (string)

Return:
(string)

tr({src}, {fromstr}, {tostr}) tr()

Translates characters in {src}, replacing each character that appears in {fromstr} with the corresponding character in {tostr}. Exactly like the unix "tr" command.
This code also deals with multibyte characters properly.

Returns an empty string on error.

Examples:

```
echo tr("hello there", "ht", "HT")
```

returns "Hello THere"

```
echo tr("<blob>", "<>", "{}")
```

returns "{blob}"

Attributes:
api-fast

Parameters:
- {src} (string)
- {fromstr} (string)
- {tostr} (string)

Return:
(string)

trim({text} [, {mask} [, {dir}]]) trim()

Lua: Prefer vim.trim().

Return {text} as a String where any character in {mask} is removed from the beginning and/or end of {text}.

If {mask} is not given, or is an empty string, {mask} is all characters up to 0x20, which includes Tab, space, NL and CR, plus the non-breaking space character 0xa0.

The optional {dir} argument specifies where to remove the characters:
0 remove from the beginning and end of {text}
1 remove only at the beginning of {text}
2 remove only at the end of {text}
When omitted both ends are trimmed.

This function deals with multibyte characters properly. Returns an empty string on error.

Examples:

```
echo trim("   some text ")
```

returns "some text"

```
echo trim("  \r\t\t\r RESERVE \t\n\x0B\xA0") .. "_TAIL"
```

returns "RESERVE_TAIL"

```
echo trim("rm<Xrm<>X>rrm", "rm<>")
```

returns "Xrm<>X" (characters in the middle are not removed)

```
echo trim("  vim  ", " ", 2)
```

returns " vim"

Attributes:
api-fast

Parameters:
- {text} (string)
- {mask} (string?)
- {dir} (0|1|2?)

Return:
(string)

trunc({expr}) trunc()

Lua: Prefer math.modf() (first return value).

Return the largest integral value with magnitude less than or equal to {expr} as a Float (truncate towards zero). {expr} must evaluate to a Float or a Number. Returns 0.0 if {expr} is not a Float or a Number. Examples:

```
echo trunc(1.456)
```

1.0

```
echo trunc(-5.456)
```

-5.0

```
echo trunc(4.0)

                    4.0
```

Parameters:
- {expr} (number)

Return:
(integer)

type({expr}) type()

Lua: Prefer lua-type() for most Lua type checks; Vim type IDs differ.

Returns the type of {expr} as a Number.
Instead of using the number directly, it is better to use the v:t_ variable that has the value:

Number:	0	v:t_number
String:	1	v:t_string
Funcref:	2	v:t_func
List:	3	v:t_list
Dictionary:	4	v:t_dict
Float:	5	v:t_float
Boolean:	6	v:t_bool (v:false and v:true)
Null:	7	(v:null)
Blob:	10	v:t_blob

For backward compatibility, this method can be used:

```
if type(myvar) == type(0) | endif
if type(myvar) == type("") | endif
if type(myvar) == type(function("tr")) | endif
if type(myvar) == type([]) | endif
if type(myvar) == type({}) | endif
if type(myvar) == type(0.0) | endif
if type(myvar) == type(v:true) | endif
```

In place of checking for v:null type it is better to check for v:null directly as it is the only value of this type:

```
if myvar is v:null | endif
```

To check if the v:t_ variables exist use this:

```
if exists('v:t_number') | endif
```

Attributes:
api-fast

Parameters:
- {expr} (any)

Return:
(integer)

undofile({name}) undofile()

Return the name of the undo file that would be used for a file with name {name} when writing. This uses the 'undodir' option, finding directories that exist. It does not check if the undo file exists.
{name} is always expanded to the full path, since that is what is used internally.
If {name} is empty undofile() returns an empty string, since a buffer without a file name will not write an undo file.
Useful in combination with :wundo and :rundo.

Parameters:
- {name} (string)

Return:
(string)

undotree([{buf}]) undotree()

Return the current state of the undo tree for the current buffer, or for a specific buffer if {buf} is given. The result is a dictionary with the following items:

"seq_last"	The highest undo sequence number used.
"seq_cur"	The sequence number of the current position in the undo tree. This differs from "seq_last" when some changes were undone.
"time_cur"	Time last used for :earlier and related commands. Use strftime() to convert to something readable.
"save_last"	Number of the last file write. Zero when no write yet.
"save_cur"	Number of the current position in the undo tree.

"synced" Non-zero when the last undo block was synced. This happens when waiting from input from the user. See undo-blocks.
"entries" A list of dictionaries with information about undo blocks.

The first item in the "entries" list is the oldest undo item. Each List item is a Dictionary with these items:
"seq" Undo sequence number. Same as what appears in :undolist.
"time" Timestamp when the change happened. Use strftime() to convert to something readable.
"newhead" Only appears in the item that is the last one that was added. This marks the last change and where further changes will be added.
"curhead" Only appears in the item that is the last one that was undone. This marks the current position in the undo tree, the block that will be used by a redo command. When nothing was undone after the last change this item will not appear anywhere.
"save" Only appears on the last block before a file write. The number is the write count. The first write has number 1, the last one the "save_last" mentioned above.
"alt" Alternate entry. This is again a List of undo blocks. Each item may again have an "alt" item.

Parameters:
- {buf} (integer|string?)

Return:
(vim.fn.undotree.ret)

uniq({list} [, {func} [, {dict}]]) uniq() E882

Lua: Prefer vim.list.unique().

Remove second and succeeding copies of repeated adjacent {list} items in-place. Returns {list}. If you want a list to remain unmodified make a copy first:

```
let newlist = uniq(copy(mylist))
```

The default compare function uses the string representation of each item. For the use of {func} and {dict} see sort(). For deduplicating text in the current buffer see :uniq.

Returns zero if {list} is not a List.

Parameters:
- {list} (any)
- {func} (any?)
- {dict} (any?)

Return:
(any[]|0)

utf16idx({string}, {idx} [, {countcc} [, {charidx}]]) utf16idx()

Lua: Prefer vim.str_utfindex() with "utf-16" and strict_indexing = false; countcc and charidx semantics differ.

Same as charidx() but returns the UTF-16 code unit index of the byte at {idx} in {string} (after converting it to UTF-16).

When {charidx} is present and TRUE, {idx} is used as the character index in the String {string} instead of as the byte index.
An {idx} in the middle of a UTF-8 sequence is rounded downwards to the beginning of that sequence.

Returns -1 if the arguments are invalid or if there are less than {idx} bytes in {string}. If there are exactly {idx} bytes, the length of the string in UTF-16 code units is returned.

See byteidx() and byteidxcomp() for getting the byte index from the UTF-16 index and charidx() for getting the character index from the UTF-16 index.
Refer to string-offset-encoding for more information.
Examples:

```
echo utf16idx('a😊😊', 3)       " returns 2
echo utf16idx('a😊😊', 7)       " returns 4
echo utf16idx('a😊😊', 1, 0, 1) " returns 2
echo utf16idx('a😊😊', 2, 0, 1) " returns 4
echo utf16idx('aą́c', 6)         " returns 2
echo utf16idx('aą́c', 6, 1)      " returns 4
echo utf16idx('a😊😊', 9)       " returns -1
```

Attributes:
api-fast

Parameters:
- {string} (string)
- {idx} (integer)
- {countcc} (boolean?)
- {charidx} (boolean?)

Return:
(integer)

values({dict}) values()

Lua: Prefer vim.tbl_values().

Return a List with all the values of {dict}. The List is in arbitrary order. Also see items() and keys(). Returns zero if {dict} is not a Dict.

Parameters:
- {dict} (any)

Return:
(any)

virtcol({expr} [, {list} [, {winid}]]) virtcol()

Returns the virtual (screen) column of the file position given with {expr}. That is, the total number of screen cells occupied by the part of the line until the end of the character at that position. When there is a <Tab> at the position, the returned Number will be the column at the end of the <Tab>. For example, for a <Tab> in column 1, with 'ts' set to 8, it returns 8. conceal is ignored. For the byte position use col().

For the use of {expr} see getpos() and col(). When {expr} is "$", it means the end of the cursor line, so the result is the number of cells in the cursor line plus one.

When 'virtualedit' is used {expr} can be [lnum, col, off], where "off" is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character. When "off" is omitted zero is used. When Virtual editing is active in the current mode, a position beyond the end of the line can be returned. Also see 'virtualedit'

If {list} is present and non-zero then virtcol() returns a List with the first and last screen position occupied by the character.

With the optional {winid} argument the values are obtained for that window instead of the current window.

Note that only marks in the current file can be used. Examples:

```
" With text "foo^Lbar" and cursor on the "^L":

echo virtcol(".")       " returns 5
echo virtcol(".", 1)    " returns [4, 5]
echo virtcol("$")       " returns 9

" With text "     there", with 't at 'h':

echo virtcol("'t")      " returns 6
```

The first column is 1. 0 or [0, 0] is returned for an error.

A more advanced example that echoes the maximum length of all lines:

```
echo max(map(range(1, line('$')), "virtcol([v:val, '$'])"))
```

Parameters:
- {expr} (string|any[])

- {list} (boolean?)

- {winid} (integer?)

Return:
(integer|[integer, integer])

virtcol2col({winid}, {lnum}, {col}) virtcol2col()

Converts a virtual column to a byte index. Returns the byte index of the character in window {winid} at buffer line {lnum} and virtual column {col}.

If buffer line {lnum} is an empty line, 0 is returned.

If {col} is greater than the last virtual column in line {lnum}, then the byte index of the character at the last virtual column is returned.

For a multi-byte character, the column number of the first byte in the character is returned.

{winid} is a window-number or window-ID. If zero, the current window is used.

Returns -1 if the window {winid} doesn't exist or the buffer line {lnum} or virtual column {col} is invalid.

See also screenpos(), virtcol() and col().

Parameters:
- {winid} (integer)

- {lnum} (integer)

- {col} (integer)

Return:
(integer)

visualmode([{expr}]) visualmode()

Returns a String describing the last Visual mode used in the current buffer. Initially it returns an empty string, but once Visual mode has been used, it returns "v", "V", or "<CTRL-V>" (a single CTRL-V character) for character-wise, line-wise, or block-wise Visual mode respectively.
Example:

```
exe "normal " .. visualmode()
```

This enters the same Visual mode as before. It is also useful in scripts if you wish to act differently depending on the Visual mode that was used.
If Visual mode is active, use mode() to get the Visual mode (e.g., in a :vmap).
If {expr} is supplied and it evaluates to a non-zero Number or a non-empty String, then the Visual mode will be cleared and the old value is returned. See non-zero-arg.

Parameters:
- {expr} (boolean?)

Return:
(string)

wait({timeout}, {condition} [, {interval}]) wait()

Lua: Prefer vim.wait().

Waits until {condition} evaluates to TRUE, where {condition} is a Funcref or string containing an expression.

{timeout} is the maximum waiting time in milliseconds, -1 means forever.

Condition is evaluated on user events, internal events, and every {interval} milliseconds (default: 200).

Returns a status integer:
	0 if the condition was satisfied before timeout
	-1 if the timeout was exceeded
	-2 if the function was interrupted (by CTRL-C)
	-3 if an error occurred

Parameters:
- {timeout} (integer)

- {condition} (any)

- {interval} (number?)

Return:
(any)

wildmenumode() wildmenumode()

Returns TRUE when the wildmenu is active and FALSE
otherwise. See 'wildmenu' and 'wildmode'.
This can be used in mappings to handle the 'wildcharm' option
gracefully. (Makes only sense with mapmode-c mappings).

For example to make <c-j> work like <down> in wildmode, use:

```
cnoremap <expr> <C-j> wildmenumode() ? "\<Down>\<Tab>" : "\<c-j>"
```

(**Note:** this needs the 'wildcharm' option set appropriately).

Return:
(any)

wildtrigger() wildtrigger()

Start wildcard expansion in the command-line, using the
behavior defined by the 'wildmode' and 'wildoptions' settings.

This function also enables completion in search patterns such
as /, ?, :s, :g, :v and :vimgrep.

Unlike pressing 'wildchar' manually, this function does not
produce a beep when no matches are found and generally
operates more quietly. This makes it suitable for triggering
completion automatically.

Note: After navigating command-line history, the first call to
wildtrigger() is a no-op; a second call is needed to start
expansion. This is to support history navigation in
command-line autocompletion.

See cmdline-autocompletion.

Return value is always 0.

Return:
(number)

win_execute({id}, {command} [, {silent}]) win_execute()

Lua: Prefer nvim_win_call().

Like execute() but in the context of window {id}.
The window will temporarily be made the current window,
without triggering autocommands or changing directory. When
executing {command} autocommands will be triggered, this may
have unexpected side effects. Use :noautocmd if needed.
Example:

```
call win_execute(winid, 'syntax enable')
```

Doing the same with setwinvar() would not trigger
autocommands and not actually show syntax highlighting.

When window {id} does not exist then no error is given and
an empty string is returned.

Parameters:
- {id} (integer)

- {command} (string)

- {silent} (boolean?)

Return:
(any)

win_findbuf({bufnr}) win_findbuf()

Lua: Prefer nvim_list_wins() with nvim_win_get_buf().

Returns a List with window-IDs for windows that contain
buffer {bufnr}. When there is none the list is empty.

Parameters:
- {bufnr} (integer)

Return:
(integer[])

win_getid([{win} [, {tab}]]) win_getid()

Lua: Prefer nvim_get_current_win() when omitted, or

nvim_tabpage_list_wins() with nvim_win_get_number() after
resolving {tab}; invalid windows return 0 in Vimscript.

Get the window-ID for the specified window.
When {win} is missing use the current window.
With {win} this is the window-number.
Without {tab} use the current tab, otherwise the
tabpage-number given by {tab}.
Return zero if the window cannot be found.

Parameters:
- {win} (integer?)

- {tab} (integer?)

Return:
(integer)

win_gettype([{nr}]) win_gettype()

Gets the type of the given window, or current window if {nr}
is omitted:
- (empty) Normal window

- "autocmd" Internal "context-switch" window.

- "command" Command-line window cmdwin

- "loclist" location-list-window

- "popup" Floating window api-floatwin

- "preview" Preview window preview-window

- "quickfix" quickfix-window

- "unknown" Window {nr} not found

See also the 'buftype' option.

Parameters:
- {nr} (integer?)

Return:
('autocmd'|'command'|''|'loclist'|'popup'|'preview'|'quickfix'|'unknown')

win_gotoid({expr}) win_gotoid()

Lua: Prefer nvim_set_current_win(); invalid IDs error
instead of returning FALSE.

Go to window-ID {expr}. May change the current tabpage.
Return TRUE if successful, FALSE if the window cannot be
found.

Parameters:
- {expr} (integer)

Return:
(0|1)

win_id2tabwin({expr}) win_id2tabwin()

Lua: Prefer nvim_win_get_tabpage() and
nvim_win_get_number() for valid windows; invalid IDs error
instead of returning [0, 0].

Return [tabnr, winnr] for window with window-ID {expr}, where
tabnr is the tabpage-number and winnr is the window-number.
Return [0, 0] if the window cannot be found.

Parameters:
- {expr} (integer)

Return:
(any)

win_id2win({expr}) win_id2win()

Lua: Prefer nvim_win_get_number() for valid windows; windows
outside the current tabpage and invalid IDs differ.

Return the window-number of for the given window-ID {expr}.
Return 0 if the window cannot be found in the current tabpage.

Parameters:
- {expr} (integer)

Return:
(integer)

win_move_separator({nr}, {offset}) win_move_separator()

Move window {nr}'s vertical separator (i.e., the right border) by {offset} columns, as if being dragged by the mouse. {nr} is a window-number or window-ID. A positive {offset} moves right and a negative {offset} moves left. Moving a window's vertical separator will change the width of the window and the width of other windows adjacent to the vertical separator. The magnitude of movement may be smaller than specified (e.g., as a consequence of maintaining 'winminwidth'). Returns TRUE if the window can be found and FALSE otherwise.
This will fail for the rightmost window and a full-width window, since it has no separator on the right.
Only works for the current tabpage. E1308

Parameters:
- {nr} (integer)
- {offset} (integer)

Return:
(any)

win_move_statusline({nr}, {offset}) win_move_statusline()

Move window {nr}'s status line (i.e., the bottom border) by {offset} rows, as if being dragged by the mouse. {nr} is a window-number or window-ID. A positive {offset} moves down and a negative {offset} moves up. Moving a window's status line will change the height of the window and the height of other windows adjacent to the status line. The magnitude of movement may be smaller than specified (e.g., as a consequence of maintaining 'winminheight'). Returns TRUE if the window can be found and FALSE otherwise.
Only works for the current tabpage.

Parameters:
- {nr} (integer)
- {offset} (integer)

Return:
(any)

win_screenpos({nr}) win_screenpos()

Lua: Prefer nvim_win_get_position() and add 1 to row and col; invalid-window semantics differ.

Return the screen position of window {nr} as a list with two numbers: [row, col]. The first window always has position [1, 1], unless there is a tabline, then it is [2, 1].
{nr} is a window-number or window-ID. Use zero for the current window.
Returns [0, 0] if the window cannot be found.

Parameters:
- {nr} (integer)

Return:
(any)

win_splitmove({nr}, {target} [, {options}]) win_splitmove()

Temporarily switch to window {target}, then move window {nr} to a new split adjacent to {target}.
Unlike commands such as :split, no new windows are created (the window-ID of window {nr} is unchanged after the move).

Both {nr} and {target} are a window-number or window-ID.
Both must be in the current tabpage.

Returns zero for success, non-zero for failure.

{options} is a Dictionary with the following optional entries:
- "vertical" When TRUE, the split is created vertically, like with :vsplit.
- "rightbelow" When TRUE, the split is made below or to the right (if vertical). When FALSE, it is done

above or to the left (if vertical). When not present, the values of 'splitbelow' and 'splitright' are used.

Parameters:
- {nr} (integer)
- {target} (integer)
- {options} (table?)

Return:
(any)

winbufnr({nr}) winbufnr()

Lua: Prefer nvim_win_get_buf().

Returns the buffer number associated with window {nr} (window-number or window-ID).
When {nr} is zero, the number of the buffer in the current window is returned.
When window {nr} doesn't exist, -1 is returned.
Example:

```
echo "The file in the current window is " .. bufname(winbufnr(0))
```

Parameters:
- {nr} (integer)

Return:
(integer)

wincol() wincol()

Returns the virtual column of the cursor in the window. This is counting screen cells from the left side of the window. The leftmost column is one.

Return:
(integer)

windowsversion() windowsversion()

Returns the Windows OS version as a String. E.g, Windows 10 is "10.0", Windows 8 is "6.2", Windows XP is "5.1". For non-MS-Windows systems the result is an empty string.

Lua: see uv.os_uname().

Attributes:
api-fast

Return:
(string)

winheight({nr}) winheight()

Gets the height of window-ID {nr} (zero for "current window"), excluding any 'winbar' and 'statusline'. Returns -1 if window {nr} doesn't exist. An existing window always has a height of zero or more.

Examples:

```
echo "Current window has " .. winheight(0) .. " lines."
```

Parameters:
- {nr} (integer)

Return:
(integer)

winlayout([{tabnr}]) winlayout()

Returns the layout of windows in a tabpage as a nested List.

Without {tabnr} use the current tabpage, otherwise the tabpage with number {tabnr}. If the tabpage {tabnr} is not found, returns an empty list.

For a leaf window, it returns:

```
["leaf", {winid}]
```

For horizontally split windows, which form a column, it returns:

```
["col", [{nested list of windows}]]
```

For vertically split windows, which form a row, it returns:

```
["row", [{nested list of windows}]]
```

Example:

```
" Only one window in the tabpage
echo winlayout()
```

```
['leaf', 1000]
```

```
" Two horizontally split windows
echo winlayout()
```

```
['col', [['leaf', 1000], ['leaf', 1001]]]
```

```
" The second tabpage, with three horizontally split
" windows, with two vertically split windows in the
" middle window
echo winlayout(2)
```

```
['col', [['leaf', 1002], ['row', [['leaf', 1003],
                    ['leaf', 1001]]], ['leaf', 1000]]]
```

Parameters:
- {tabnr} (integer?)

Return:
(vim.fn.winlayout.ret)

winline() winline()

Returns the screen line of the cursor in the window. This is counting screen lines from the top of the window. The first line is one.
If the cursor was moved the view on the file will be updated first, this may cause a scroll.

Return:
(integer)

winnr([{arg}]) winnr()

Lua: Prefer nvim_win_get_number() with nvim_get_current_win() for the current window, or nvim_tabpage_list_wins() with nvim_get_current_tabpage() for "$"; "#", motion args, and hidden windows differ.

Returns the number of the current window. The top window has number 1. Returns zero for a hidden or non focusable window, unless it is the current window.

The optional argument {arg} supports the following values:

$	the number of the last window (the window count).
#	the number of the last accessed window (where CTRL-W_p goes to). If there is no previous window or it is in another tabpage, 0 is returned. May refer to the current window in some cases (e.g. when evaluating 'statusline' expressions).
{N}j	the number of the Nth window below the current window (where CTRL-W_j goes to).
{N}k	the number of the Nth window above the current window (where CTRL-W_k goes to).
{N}h	the number of the Nth window left of the current window (where CTRL-W_h goes to).
{N}l	the number of the Nth window right of the current window (where CTRL-W_l goes to).

The number can be used with CTRL-W_w and ":wincmd w" :wincmd.
When {arg} is invalid an error is given and zero is returned.
Also see tabpagewinnr() and win_getid().
Examples:

```
let window_count = winnr('$')
let prev_window = winnr('#')
let wnum = winnr('3k')
```

Parameters:
- {arg} (string|integer?)

Return:
(integer)

winrestcmd() winrestcmd()

Returns a sequence of :resize commands that should restore the current window sizes. Only works properly when no windows are opened or closed and the current window and tabpage is

unchanged.
Example:

```
let cmd = winrestcmd()
call MessWithWindowSizes()
exe cmd
```

Return:
(string)

winrestview({dict}) winrestview()

Uses the Dictionary returned by winsaveview() to restore the view of the current window.
Note: The {dict} does not have to contain all values, that are returned by winsaveview(). If values are missing, those settings won't be restored. So you can use:

```
call winrestview({'curswant': 4})
```

This will only set the curswant value (the column the cursor wants to move on vertical movements) of the cursor to column 5 (yes, that is 5), while all other settings will remain the same. This is useful, if you set the cursor position manually.

If you have changed the values the result is unpredictable. If the window size changed the result won't be the same.

Parameters:
- {dict} (vim.fn.winrestview.dict)

Return:
(any)

winsaveview() winsaveview()

Returns a Dictionary that contains information to restore the view of the current window. Use winrestview() to restore the view.
This is useful if you have a mapping that jumps around in the buffer and you want to go back to the original view.
This does not save fold information. Use the 'foldenable' option to temporarily switch off folding, so that folds are not opened when moving around. This may have side effects.
The return value includes:

lnum	cursor line number
col	cursor column (**Note:** the first column zero, as opposed to what getcurpos() returns)
coladd	cursor column offset for 'virtualedit'
curswant	column for vertical movement (**Note:** the first column is zero, as opposed to what getcurpos() returns). After $ command it will be a very large number equal to v:maxcol.
topline	first line in the window
topfill	filler lines, only in diff mode
leftcol	first column displayed; only used when 'wrap' is off
skipcol	columns skipped

Note that no option values are saved.

Return:
(vim.fn.winsaveview.ret)

winwidth({nr}) winwidth()

Gets the width of window-ID {nr} (zero for "current window"), including columns (sign-column, 'statuscolumn', etc.). Returns -1 if window {nr} doesn't exist. An existing window always has a width of zero or more.

Example:

```
echo "Current window has " .. winwidth(0) .. " columns."
if winwidth(0) <= 50
  50 wincmd |
endif
```

To get the buffer "viewport", use getwininfo():

```
:echo getwininfo(win_getid())[0].width - getwininfo(win_getid())[0].textoff
```

To get the Nvim screen size, see the 'columns' option.

Parameters:
- {nr} (integer)

Return:
(integer)

wordcount() wordcount()

Returns a dictionary of byte/chars/word statistics for the current buffer. This is the same info provided by g_CTRL-G. The return value includes:

bytes	Number of bytes in the buffer
chars	Number of chars in the buffer
words	Number of words in the buffer
cursor_bytes	Number of bytes before cursor position (not in Visual mode)
cursor_chars	Number of chars before cursor position (not in Visual mode)
cursor_words	Number of words before cursor position (not in Visual mode)
visual_bytes	Number of bytes visually selected (only in Visual mode)
visual_chars	Number of chars visually selected (only in Visual mode)
visual_words	Number of words visually selected (only in Visual mode)

Return:
(any)

writefile({data}, {fname} [, {flags}]) writefile()

Writes {data} to file {fname}.

- When {data} is a Blob its bytes are written unmodified (even if binary mode "b" is not specified).
- When {data} is a Lua string, it is treated as a blob.
- When {data} is a List, each list item is treated as a text line (terminated with a newline). Each list item must be a String or Number.
  - Any NL (newline) chars in the line are treated as a NUL character. (This is a workaround to allow Vimscript to write binary data, and is irrelevant for Lua, which should just pass a string instead.)

{flags} must be a String. These characters are recognized:

'b' Binary mode is used: There will not be a NL after the last list item. An empty item at the end does cause the last line in the file to end in a NL.

'a' Append mode is used, lines are appended to the file:

```
call writefile(["foo"], "event.log", "a")
call writefile(["bar"], "event.log", "a")
```

'D' Delete the file when the current function ends. This works like:

```
defer delete({fname})
```

Fails when not in a function. Also see :defer.

's' fsync() is called after writing the file. This flushes the file to disk, if possible. This takes more time but avoids losing the file if the system crashes.

'S' fsync() is not called, even when 'fsync' is set.

When {flags} does not contain "S" or "s" then fsync() is called if the 'fsync' option is set.

An existing file is overwritten, if possible.

When the write fails -1 is returned, otherwise 0. There is an error message if the file can't be created or when writing fails.

Also see readfile().
To copy a file byte for byte:

```
let fl = readfile("foo", "b")
call writefile(fl, "foocopy", "b")
```

Parameters:
- {data} (any)
- {fname} (string)
- {flags} (string?)

Return:
(any)

xor({expr}, {expr}) xor()

Lua: Prefer bit.bxor().

Bitwise XOR on the two arguments. The arguments are converted to a number. A List, Dict or Float argument causes an error. Also see and() and or(). Example:

```
let bits = xor(bits, 0x80)
```

Parameters:
- {expr} (integer)

- {expr1} (integer)

Return:
(integer)

2. Matching a pattern in a String string-match

This is common between several functions. A regexp pattern as explained at pattern is normally used to find a match in the buffer lines. When a pattern is used to find a match in a String, almost everything works in the same way. The difference is that a String is handled like it is one line. When it contains a "\n" character, this is not seen as a line break for the pattern. It can be matched with a "\n" in the pattern, or with ".". Example:

```
let a = "aaaa\nxxxx"
echo matchstr(a, "..\n..")
" aa
" xx
echo matchstr(a, "a.x")
" a
" x
```

Don't forget that "^" will only match at the first character of the String and "$" at the last character of the string. They don't match after or before a "\n".

Vimscript and debugging

This reference describes commands for running and debugging Vimscript.
For details on authoring Vimscript, see: expression vimscript-functions

Using Vimscript using-scripts

For writing a Vim script, see chapter 41 of the user manual usr_41.txt.

:so :source

:so[urce] {file} Runs Ex-commands or Lua code (".lua" files) from {file}. Triggers the SourcePre autocommand.

:[range]so[urce] Read Ex commands or Lua code from the [range] of lines in the current buffer. When [range] is omitted read all lines. The buffer is treated as Lua code if its 'filetype' is "lua" or its filename ends with ".lua".

When sourcing commands or Lua code from the current buffer, the same script-ID <SID> is used even if the buffer is sourced multiple times. If a buffer is sourced more than once, then the functions in the buffer are defined again.

Implementation detail: When sourcing a [range] of lines that falls inside a folded region, the range will be adjusted to the start and end of the fold, but only if a two line specifiers range was used.

:source!

:so[urce]! {file} Runs Normal-mode commands from {file}. When used after :global, :argdo, :windo, :bufdo, in a loop or when another command follows the display won't be updated while executing the commands.

:ru :runtime

:ru[ntime][!] [where] {file} ..
Sources Ex commands or Lua code (".lua" files) read from {file} (a relative path) in each directory given by 'runtimepath' and/or 'packpath'.
Ignores non-existing files.

Example:

```
:runtime syntax/c.vim
:runtime syntax/c.lua
```

There can be multiple space-separated {file} arguments. Each {file} is searched for in the first directory from 'runtimepath', then in the second directory, etc.

When [!] is included, all found files are sourced. Else only the first found file is sourced.

When [where] is omitted only 'runtimepath' is used. Other values:

START	search only under "start" in 'packpath'
OPT	search only under "opt" in 'packpath'
PACK	search under "start" and "opt" in 'packpath'
ALL	first use 'runtimepath', then search under "start" and "opt" in 'packpath'

When {file} contains wildcards it is expanded to all matching files. Example:

```
:runtime! plugin/**/*.{vim,lua}
```

This is what Nvim uses to load the plugin files when starting up. This similar command:

```
:runtime plugin/**/*.{vim,lua}
```

would source the first file only.

For each {file} pattern, if two .vim and .lua file names match and differ only in extension, the .vim file is sourced first.

When 'verbose' is one or higher, there is a message when no file could be found.
When 'verbose' is two or higher, there is a message about each searched file.

:pa :packadd E919

:pa[ckadd][!] {name} pack-add Search for an optional plugin directory in 'packpath', source any plugin files found, and add it to 'runtimepath'. The directory must match:

```
pack/*/opt/{name}
```

If the directory pack/*/opt/{name}/after exists it is added at the end of 'runtimepath'.

Note: Use vim.pack.add() to install from a URL.

If loading packages from "pack/*/start" was skipped,
then this directory is searched first:

```
pack/*/start/{name}
```

Note that {name} is the directory name, not the name
of the .vim file. All files matching the patterns

```
pack/*/opt/{name}/plugin/**/*.vim
pack/*/opt/{name}/plugin/**/*.lua
```

will be sourced. This allows for using subdirectories
below "plugin", just like with plugins in
'runtimepath'.

If the filetype detection was already enabled (this
is usually done with a syntax enable or filetype on
command in your vimrc, or automatically during
initialization), and the package was found in
"pack/*/opt/{name}", this command will also look
for "{name}/ftdetect/*.vim" files.

When the optional "!" is given, no plugin/ files or
ftdetect/ scripts are loaded, only the matching
directories are added to 'runtimepath'. This is
useful in your init.vim. The plugins will then be
loaded during the load-plugins initialization step
(note that the loading order will be reversed because
each directory is inserted before others), after
loading the ftdetect scripts.

To programmatically decide if ! is needed during
startup, check v:vim_did_init: use ! if 0 (to not
duplicate load-plugins step), no ! otherwise (to
force load plugin files as otherwise they won't be
loaded automatically).

:packl :packloadall

:packl[oadall][!] Load all packages in the "start" directory under each
entry in 'packpath'.

First all the directories found are added to
'runtimepath', then the plugins found in the
directories are sourced. This allows for a plugin to
depend on something of another plugin, e.g. an
"autoload" directory. See packload-two-steps for
how this can be useful.

This is normally done automatically during startup,
after loading your vimrc file. With this command it
can be done earlier.

Packages will be loaded only once. Using
:packloadall a second time will have no effect.
When the optional ! is added this command will load
packages even when done before.

Note that when using :packloadall in the vimrc
file, the 'runtimepath' option is updated, and later
all plugins in 'runtimepath' will be loaded, which
means they are loaded again. Plugins are expected to
handle that.

An error only causes sourcing the script where it
happens to be aborted, further plugins will be loaded.
See packages.

:scripte[ncoding] [encoding] :scripte :scriptencoding E167
Specify the character encoding used in the script.
The following lines will be converted from [encoding]
to the value of the 'encoding' option, if they are
different. Examples:

```
scriptencoding iso-8859-5
scriptencoding cp932
```

When [encoding] is empty, no conversion is done. This
can be used to restrict conversion to a sequence of
lines:

```
scriptencoding euc-jp
... lines to be converted ...
scriptencoding
... not converted ...
```

When conversion isn't supported by the system, there
is no error message and no conversion is done. When a
line can't be converted there is no error and the
original line is kept.

Don't use "ucs-2" or "ucs-4", scripts cannot be in
these encodings (they would contain NUL bytes).
When a sourced script starts with a BOM (Byte Order
Mark) in utf-8 format Vim will recognize it, no need
to use ":scriptencoding utf-8" then.

:scr :scriptnames

:scr[iptnames] List all sourced script names, in the order they were first sourced. The number is used for the script ID <SID>.
Also see getscriptinfo().

:scr[iptnames][!] {scriptId} :script

Edit script {scriptId}. Although ":scriptnames name" works, using ":script name" is recommended.
When the current buffer can't be abandoned and the ! is not present, the command fails.

:fini :finish E168

:fini[sh] Stop sourcing a script. Can only be used in a Vim script file. This is a quick way to skip the rest of the file. If it is used after a :try but before the matching :finally (if present), the commands following the ":finally" up to the matching :endtry are executed first. This process applies to all nested ":try"s in the script. The outermost ":endtry" then stops sourcing the script.

All commands and command sequences can be repeated by putting them in a named register and then executing it. There are two ways to get the commands in the register:

- Use the record command "q". You type the commands once, and while they are being executed they are stored in a register. Easy, because you can see what you are doing. If you make a mistake, "p"ut the register into the file, edit the command sequence, and then delete it into the register again. You can continue recording by appending to the register (use an uppercase letter).
- Delete or yank the command sequence into the register.

Often used command sequences can be put under a function key with the ':map' command.

An alternative is to put the commands in a file, and execute them with the ':source!' command. Useful for long command sequences. Can be combined with the ':map' command to put complicated commands under a function key.

The ':source' command reads Ex commands from a file or a buffer line by line. You will have to type any needed keyboard input. The ':source!' command reads from a script file character by character, interpreting each character as if you typed it.

Example: When you give the ":!ls" command you get the hit-enter prompt. If you ':source' a file with the line "!ls" in it, you will have to type the <Enter> yourself. But if you ':source!' a file with the line ":!ls" in it, the next characters from that file are read until a <CR> is found. You will not have to type <CR> yourself, unless ":!ls" was the last line in the file.

It is possible to put ':source[!]' commands in the script file, so you can make a top-down hierarchy of script files. The ':source' command can be nested as deep as the number of files that can be opened at one time (about 15). The ':source!' command can be nested up to 15 levels deep.

You can use the "<script>" string (literally, this is not a special key) inside of the sourced file, in places where a file name is expected. It will be replaced by the file name of the sourced file. For example, if you have a "other.vimrc" file in the same directory as your init.vim file, you can source it from your init.vim file with this command:

```
:source <script>:h/other.vimrc
```

In script files terminal-dependent key codes are represented by terminal-independent two character codes. This means that they can be used in the same way on different kinds of terminals. The first character of a key code is 0x80 or 128, shown on the screen as "~@". The second one can be found in the list key-notation. Any of these codes can also be entered with CTRL-V followed by the three digit decimal code.

:source_crnl W15

Windows: Files that are read with ":source" normally have <CR><NL> <EOL>s. These always work. If you are using a file with <NL> <EOL>s (for example, a file made on Unix), this will be recognized if 'fileformats' is not empty and the first line does not end in a <CR>. This fails if the first line has something like ":map <F1> :help^M", where "^M" is a <CR>. If the first line ends in a <CR>, but following ones don't, you will get an error message, because the <CR> from the first lines will be lost.

On other systems, Vim expects ":source"ed files to end in a <NL>. These always work. If you are using a file with <CR><NL> <EOL>s (for example, a file made on MS-Windows), all lines will have a trailing <CR>. This may cause problems for some commands (e.g., mappings). There is no automatic <EOL> detection, because it's common to start with a line that defines a mapping that ends in a <CR>, which will confuse the automaton.

line-continuation

Long lines in a ":source"d Ex command script file can be split by inserting

a line continuation symbol "\" (backslash) at the start of the next line.
There can be white space before the backslash, which is ignored.

Example: the lines

```
:set comments=sr:/*,mb:*,el:*/,
             \://,
             \b:#,
             \:%,
             \n:>,
             \fb:-
```

are interpreted as if they were given in one line:

```
:set comments=sr:/*,mb:*,el:*/,://,b:#,:%,n:>,fb:-
```

All leading whitespace characters in the line before a backslash are ignored.
Note however that trailing whitespace in the line before it cannot be
inserted freely; it depends on the position where a command is split up
whether additional whitespace is allowed or not.

When a space is required it's best to put it right after the backslash. A
space at the end of a line is hard to see and may be accidentally deleted.

```
:syn match Comment
        \ "very long regexp"
        \ keepend
```

There is a problem with the ":append" and ":insert" commands:

```
:1append
\asdf
.
```

The backslash is seen as a line-continuation symbol, thus this results in the
command:

```
:1appendasdf
.
```

To avoid this, add the 'C' flag to the 'cpoptions' option:

```
:set cpo+=C
:1append
\asdf
.
:set cpo-=C
```

Note that when the commands are inside a function, you need to add the 'C'
flag when defining the function, it is not relevant when executing it.

```
:set cpo+=C
:function Foo()
:1append
\asdf
.
:endfunction
:set cpo-=C
```

line-continuation-comment

To add a comment in between the lines start with '"\ '. Notice the space
after the backslash. Example:

```
let array = [
         "\ first entry comment
         \ 'first',
         "\ second entry comment
         \ 'second',
         \ ]
```

Rationale:
        Most programs work with a trailing backslash to indicate line
        continuation. Using this in Vim would cause incompatibility with Vi.
        For example for this Vi mapping:

```
:map xx  asdf\
```

        Therefore the unusual leading backslash is used.

        Starting a comment in a continuation line results in all following
        continuation lines to be part of the comment. Since it was like this
        for a long time, when making it possible to add a comment halfway a
        sequence of continuation lines, it was not possible to use \", since

that was a valid continuation line. Using '"\ ' comes closest, even
though it may look a bit weird. Requiring the space after the
backslash is to make it very unlikely this is a normal comment line.

Debugging scripts

debug-scripts

Besides the obvious messages that you can add to your scripts to find out what they are doing, Vim offers a debug mode. This allows you to step through a sourced file or user function and set breakpoints.

NOTE: The debugging mode is far from perfect. Debugging will have side effects on how Vim works. You cannot use it to debug everything. For example, the display is messed up by the debugging messages.

An alternative to debug mode is setting the 'verbose' option. With a bigger number it will give more verbose messages about what Vim is doing.

STARTING DEBUG MODE

debug-mode

To enter debugging mode use one of these methods:

1. Start Vim with the -D argument:

```
vim -D file.txt
```

   Debugging will start as soon as the first vimrc file is sourced. This is useful to find out what is happening when Vim is starting up. A side effect is that Vim will switch the terminal mode before initialisations have finished, with unpredictable results.
   For a GUI-only version (Windows) the debugging will start as soon as the GUI window has been opened. To make this happen early, add a ":gui" command in the vimrc file.

:debug

2. Run a command with ":debug" prepended. Debugging will only be done while this command executes. Useful for debugging a specific script or user function. And for scripts and functions used by autocommands. Example:

```
:debug edit test.txt.gz
```

3. Set a breakpoint in a sourced file or user function. You could do this in the command line:

```
vim -c "breakadd file */explorer.vim" .
```

   This will run Vim and stop in the first line of the "explorer.vim" script.
   Breakpoints can also be set while in debugging mode.

In debugging mode every executed command is displayed before it is executed. Comment lines, empty lines and lines that are not executed are skipped. When a line contains two commands, separated by "|", each command will be displayed separately.

DEBUG MODE

Once in debugging mode, the usual Ex commands can be used. For example, to inspect the value of a variable:

```
echo idx
```

When inside a user function, this will print the value of the local variable "idx". Prepend "g:" to get the value of a global variable:

```
echo g:idx
```

All commands are executed in the context of the current function or script. You can also set options, for example setting or resetting 'verbose' will show what happens, but you might want to set it just before executing the lines you are interested in:

```
:set verbose=20
```

Commands that require updating the screen should be avoided, because their effect won't be noticed until after leaving debug mode. For example:

```
:help
```

won't be very helpful.

There is a separate command-line history for debug mode.

The line number for a function line is relative to the start of the function. If you have trouble figuring out where you are, edit the file that defines

the function in another Vim, search for the start of the function and do
"99j". Replace "99" with the line number.

Additionally, these commands can be used:

>cont

cont Continue execution until the next breakpoint is hit.

>quit

quit Abort execution. This is like using CTRL-C, some
things might still be executed, doesn't abort
everything. Still stops at the next breakpoint.

>next

next Execute the command and come back to debug mode when
it's finished. This steps over user function calls
and sourced files.

>step

step Execute the command and come back to debug mode for
the next command. This steps into called user
functions and sourced files.

>interrupt

interrupt This is like using CTRL-C, but unlike ">quit" comes
back to debug mode for the next command that is
executed. Useful for testing :finally and :catch
on interrupt exceptions.

>finish

finish Finish the current script or user function and come
back to debug mode for the command after the one that
sourced or called it.

>bt

>backtrace

>where

backtrace Show the call stacktrace for current debugging
session.
bt
where

>frame

frame N Goes to N backtrace level. + and - signs make movement
relative. E.g., ":frame +3" goes three frames up.

>up

up Goes one level up from call stacktrace.

>down

down Goes one level down from call stacktrace.

About the additional commands in debug mode:

- There is no command-line completion for them, you get the completion for the normal Ex commands only.
- You can shorten them, up to a single character, unless more than one command starts with the same letter. "f" stands for "finish", use "fr" for "frame".
- Hitting <CR> will repeat the previous one. When doing another command, this is reset (because it's not clear what you want to repeat).
- When you want to use the Ex command with the same name, prepend a colon: ":cont", ":next", ":finish" (or shorter).

The backtrace shows the hierarchy of function calls, e.g.:

```
>bt
3 function One[3]
2 Two[3]
->1 Three[3]
0 Four
line 1: let four = 4
```

The "->" points to the current frame. Use "up", "down" and "frame N" to
select another frame.

In the current frame you can evaluate the local function variables. There is
no way to see the command at the current line yet.

DEFINING BREAKPOINTS

:breaka :breakadd

:breaka[dd] func [lnum] {name}
Set a breakpoint in a function. Example:

```
:breakadd func Explore
```

Doesn't check for a valid function name, thus the breakpoint can be set before the function is defined.

:breaka[dd] file [lnum] {name}
Set a breakpoint in a sourced file. Example:

```
:breakadd file 43 init.vim
```

:breaka[dd] here
Set a breakpoint in the current line of the current file. Like doing:

```
:breakadd file <cursor-line> <current-file>
```

Note that this only works for commands that are executed when sourcing the file, not for a function defined in that file.

:breaka[dd] expr {expression}
Sets a breakpoint, that will break whenever the {expression} evaluates to a different value. Example:

```
:breakadd expr g:lnum
```

Will break, whenever the global variable lnum changes.

Errors in evaluation are suppressed, you can use the name of a variable that does not exist yet. This also means you will not notice anything if the expression has a mistake.

Note if you watch a script-variable this will break when switching scripts, since the script variable is only valid in the script where it has been defined and if that script is called from several other scripts, this will stop whenever that particular variable will become visible or inaccessible again.

The [lnum] is the line number of the breakpoint. Vim will stop at or after this line. When omitted line 1 is used.

:debug-name

{name} is a pattern that is matched with the file or function name. The pattern is like what is used for autocommands. There must be a full match (as if the pattern starts with "^" and ends in "$"). A "*" matches any sequence of characters. 'ignorecase' is not used, but "\c" can be used in the pattern to ignore case /\c. Don't include the () for the function name!

The match for sourced scripts is done against the full file name. If no path is specified the current directory is used. Examples:

```
breakadd file explorer.vim
```

matches "explorer.vim" in the current directory.

```
breakadd file *explorer.vim
```

matches ".../plugin/explorer.vim", ".../plugin/iexplorer.vim", etc.

```
breakadd file */explorer.vim
```

matches ".../plugin/explorer.vim" and "explorer.vim" in any other directory.

The match for functions is done against the name as it's shown in the output of ":function". For local functions this means that something like "<SNR>99_" is prepended.

Note that functions are first loaded and later executed. When they are loaded the "file" breakpoints are checked, when they are executed the "func" breakpoints.

DELETING BREAKPOINTS

:breakd :breakdel E161

:breakd[el] {nr}
Delete breakpoint {nr}. Use :breaklist to see the number of each breakpoint.

:breakd[el] *
Delete all breakpoints.

:breakd[el] func [lnum] {name}
Delete a breakpoint in a function.

:breakd[el] file [lnum] {name}
Delete a breakpoint in a sourced file.

:breakd[el] here
Delete a breakpoint at the current line of the current file.

When [lnum] is omitted, the first breakpoint in the function or file is deleted.

The {name} must be exactly the same as what was typed for the ":breakadd"
command. "explorer", "*explorer.vim" and "*explorer*" are different.

LISTING BREAKPOINTS

:breakl[ist] :breakl :breaklist
List all breakpoints.

OBSCURE

:debugg[reedy] :debugg :debuggreedy
Read debug mode commands from the normal input stream, instead
of getting them directly from the user. Only useful for test
scripts. Example:

```
echo 'q^Mq' | vim -e -s -c debuggreedy -c 'breakadd file script.vim' -S script.vim
```

:0debugg[reedy]
Undo ":debuggreedy": get debug mode commands directly from the
user, don't use typeahead for debug commands.

Profiling profile profiling

Profiling means that Vim measures the time that is spent on executing
functions and/or scripts.

You can also use the reltime() function to measure time.

For profiling syntax highlighting see :syntime.

For example, to profile the one_script.vim script file:

```
:profile start /tmp/one_script_profile
:profile file one_script.vim
:source one_script.vim
:exit
```

:prof[ile] start {fname} :prof :profile E750
Start profiling, write the output in {fname} upon exit or when
a :profile stop or :profile dump command is invoked.
"~/" and environment variables in {fname} will be expanded.
If {fname} already exists it will be silently overwritten.
The variable v:profiling is set to one.

:prof[ile] stop
Write the collected profiling information to the logfile and
stop profiling. You can use the :profile start command to
clear the profiling statistics and start profiling again.

:prof[ile] pause
Stop profiling until the next :profile continue command.
Can be used when doing something that should not be counted
(e.g., an external command). Does not nest.

:prof[ile] continue
Continue profiling after :profile pause.

:prof[ile] func {pattern}
Profile function that matches the pattern {pattern}.
See :debug-name for how {pattern} is used.

:prof[ile][!] file {pattern}
Profile script file that matches the pattern {pattern}.
See :debug-name for how {pattern} is used.
This only profiles the script itself, not the functions
defined in it.
When the [!] is added then all functions defined in the script
will also be profiled.
Note that profiling only starts when the script is loaded
after this command. A :profile command in the script itself
won't work.

:prof[ile] dump
Write the current state of profiling to the logfile
immediately. After running this command, Vim continues to
collect the profiling statistics.

:profd[el] ... :profd :profdel
Stop profiling for the arguments specified. See :breakdel
for the arguments. Examples:

```
profdel func MyFunc
profdel file MyScript.vim
profdel here
```

You must always start with a ":profile start fname" command. The resulting
file is written when Vim exits. For example, to profile one specific
function:

```
profile start /tmp/vimprofile
profile func MyFunc
```

Here is an example of the output, with line
numbers prepended for the explanation:

```
1 FUNCTION  Test2()
2 Called 1 time
3 Total time:   0.155251
4  Self time:   0.002006
5
6 count  total (s)   self (s)
7       9              0.000096   for i in range(8)
8       8   0.153655   0.000410     call Test3()
9       8              0.000070   endfor
10                                 " Ask a question
11      1              0.001341   echo input("give me an answer: ")
```

The header (lines 1-4) gives the time for the whole function. The "Total"
time is the time passed while the function was executing. The "Self" time is
the "Total" time reduced by time spent in:

- other user defined functions
- sourced scripts
- executed autocommands
- external (shell) commands

Lines 7-11 show the time spent in each executed line. Lines that are not
executed do not count. Thus a comment line is never counted.

The Count column shows how many times a line was executed. Note that the
"for" command in line 7 is executed one more time as the following lines.
That is because the line is also executed to detect the end of the loop.

The time Vim spends waiting for user input isn't counted at all. Thus how
long you take to respond to the input() prompt is irrelevant.

Profiling should give a good indication of where time is spent, but keep in
mind there are various things that may clobber the results:

- Real elapsed time is measured, if other processes are busy they may cause
  delays at unpredictable moments. You may want to run the profiling several
  times and use the lowest results.
- If you have several commands in one line you only get one time. Split the
  line to see the time for the individual commands.
- The time of the lines added up is mostly less than the time of the whole
  function. There is some overhead in between.
- Functions that are deleted before Vim exits will not produce profiling
  information. You can check the v:profiling variable if needed:

```
:if !v:profiling
:   delfunc MyFunc
:endif
```

- Profiling may give weird results on multi-processor systems, when sleep
  mode kicks in or the processor frequency is reduced to save power.
- The "self" time is wrong when a function is used recursively.

Visual mode Visual-mode visual-mode

Visual mode is a flexible and easy way to select a piece of text for an operator. It is the only way to select a block of text (visual-block).

This is introduced in section 04.4 of the user manual.

1. Using Visual mode visual-use

Using Visual mode consists of three parts:

1. Mark the start of the text with "v", "V" or CTRL-V.

   The character under the cursor will be used as the start.
2. Move to the end of the text.

   The text from the start of the Visual mode up to and including the character under the cursor is highlighted.
3. Type an operator command.

   The highlighted characters will be operated upon.

The hl-Visual group determines the highlighting of the visual selection. The 'virtualedit' option can be used to allow positioning the cursor to positions where there is no actual character.

The highlighted text normally includes the character under the cursor. However, when the 'selection' option is set to "exclusive" and the cursor is after the Visual area, the character under the cursor is not included.

With "v" the text before the start position and after the end position will not be highlighted. However, all uppercase and non-alpha operators, except "~" and "U", will work on whole lines anyway. See the list of operators below.

visual-block

With CTRL-V (blockwise Visual mode) the highlighted text will be a rectangle between start position and the cursor. However, some operators work on whole lines anyway (see the list below). The change and substitute operators will delete the highlighted text and then start insertion at the top left position.

2. Starting and stopping Visual mode visual-start

v charwise-visual

[count]v — Start Visual mode per character.
With [count] select the same number of characters or lines as used for the last Visual operation, but at the current cursor position, multiplied by [count].
When the previous Visual operation was on a block both the width and height of the block are multiplied by [count].
When there was no previous Visual operation [count] characters are selected. This is like moving the cursor right N * [count] characters. One less when 'selection' is not "exclusive".

V linewise-visual

[count]V — Start Visual mode linewise.
With [count] select the same number of lines as used for the last Visual operation, but at the current cursor position, multiplied by [count]. When there was no previous Visual operation [count] lines are selected.

CTRL-V blockwise-visual

[count]CTRL-V — Start Visual mode blockwise.

If you use <Esc>, click the left mouse button or use any command that does a jump to another buffer while in Visual mode, the highlighting stops and no text is affected. Also when you hit "v" in charwise Visual mode, "CTRL-V" in blockwise Visual mode or "V" in linewise Visual mode. If you hit CTRL-Z the highlighting stops and the editor is suspended or a new shell is started CTRL-Z.

v_v v_CTRL-V v_V

new mode after typing:	"v"	"CTRL-V"	"V"
old mode			
Normal	Visual	blockwise Visual	linewise Visual
Visual	Normal	blockwise Visual	linewise Visual
blockwise Visual	Visual	Normal	linewise Visual
linewise Visual	Visual	blockwise Visual	Normal

gv v_gv reselect-Visual

gv — Starts Visual mode with the previous Visual area and mode. In Visual mode the current and the previous Visual area are exchanged. After using "p" or "P" in Visual mode the text that was put will be selected.

An operator target that internally creates a temporary Visual selection (gn, "d<C-v>j", an omap-info text object) does not update the previous ("gv") area (nor '< '>, visualmode()).

gn (gn v_gn)
: Searches forward for the last-used search pattern, like with n, and starts Visual mode to select the match. If the cursor is on the match, visually selects it. If an operator is pending, operates on the match. E.g., "dgn" deletes the text of the next match. If Visual mode is active, extends the selection until the end of the next match.

  The Visual marks '< '> are not changed, so "cgn" with a /\%V pattern can be repeated with .

  'wrapscan' applies.
  Note: Unlike n the search direction does not depend on the previous search command.

gN (gN v_gN)
: Like gn but searches backward, like with N.

<LeftMouse>
: Set the current cursor position. If Visual mode is active it is stopped. Only when 'mouse' option contains 'n' or 'a'. If the position is within 'so' lines from the last line on the screen the text is scrolled up. If the position is within 'so' lines from the first line on the screen the text is scrolled down.

<RightMouse>
: Start Visual mode if it is not active. The text from the cursor position to the position of the click is highlighted. If Visual mode was already active move the start or end of the highlighted text, whichever is closest, to the position of the click. Only when 'mouse' option contains 'n' or 'a'.

  Note: when 'mousemodel' is set to "popup", <S-LeftMouse> has to be used instead of <RightMouse>.

<LeftRelease>
: This works like a <LeftMouse>, if it is not at the same position as <LeftMouse>. In an older version of xterm you won't see the selected area until the button is released, unless there is access to the display where the xterm is running (via the DISPLAY environment variable or the -display argument). Only when 'mouse' option contains 'n' or 'a'.

<A-LeftMouse>
: Starts or extends the Visual area blockwise, see <A-LeftMouse>.

If Visual mode is not active and the "v", "V" or CTRL-V is preceded with a count, the size of the previously highlighted area is used for a start. You can then move the end of the highlighted area and give an operator. The type of the old area is used (character, line or blockwise).

- Linewise Visual mode: The number of lines is multiplied with the count.
- Blockwise Visual mode: The number of lines and columns is multiplied with the count.
- Normal Visual mode within one line: The number of characters is multiplied with the count.
- Normal Visual mode with several lines: The number of lines is multiplied with the count, in the last line the same number of characters is used as in the last line in the previously highlighted area.

The start of the text is the Cursor position. If the "$" command was used as one of the last commands to extend the highlighted text, the area will be extended to the rightmost column of the longest line.

If you want to highlight exactly the same area as the last time, you can use "gv" gv v_gv.

<Esc> (v_<Esc>)
: In Visual mode: Stop Visual mode.

  (v_META v_ALT)
  ALT (META) may act like <Esc> if the chord is not mapped. For example <A-x> acts like <Esc>x if <A-x> does not have a visual-mode mapping.

CTRL-C (v_CTRL-C)
: In Visual mode: Stop Visual mode. When insert mode is pending (the mode message shows "-- (insert) VISUAL --"), it is also stopped. On MS-Windows, you may need to press CTRL-Break.

3. Changing the Visual area visual-change

v_o

o Go to Other end of highlighted text: The current cursor position becomes the start of the highlighted text and the cursor is moved to the other end of the highlighted text. The highlighted area remains the same.

v_O

O Go to Other end of highlighted text. This is like "o", but in Visual block mode the cursor moves to the other corner in the same line. When the corner is at a character that occupies more than one position on the screen (e.g., a <Tab>), the highlighted text may change.

v_$

When the "$" command is used with blockwise Visual mode, the right end of the highlighted text will be determined by the longest highlighted line. This stops when a motion command is used that does not move straight up or down.

For moving the end of the block many commands can be used, but you cannot use Ex commands, commands that make changes or abandon the file. Commands (starting with) ".", "&", CTRL-^, "Z", CTRL-], CTRL-T, CTRL-R, CTRL-I and CTRL-O cause a beep and Visual mode continues.

When switching to another window on the same buffer, the cursor position in that window is adjusted, so that the same Visual area is still selected. This is especially useful to view the start of the Visual area in one window, and the end in another. You can then use <RightMouse> (or <S-LeftMouse> when 'mousemodel' is "popup") to drag either end of the Visual area.

4. Operating on the Visual area visual-operators

The operators that can be used are:

~	switch case	v_~
d	delete	v_d
c	change (4)	v_c
y	yank	v_y
>	shift right (4)	v_>
<	shift left (4)	v_<
!	filter through external command (1)	v_!
=	filter through 'equalprg' option command (1)	v_=
gq	format lines to 'textwidth' length (1)	v_gq

The objects that can be used are:

aw	a word (with white space)	v_aw
iw	inner word	v_iw
aW	a WORD (with white space)	v_aW
iW	inner WORD	v_iW
as	a sentence (with white space)	v_as
is	inner sentence	v_is
ap	a paragraph (with white space)	v_ap
ip	inner paragraph	v_ip
al	all lines	v_al
il	inner line	v_il
ab	a () block (with parentheses)	v_ab
ib	inner () block	v_ib
aB	a {} block (with braces)	v_aB
iB	inner {} block	v_iB
at	a <tag> </tag> block (with tags)	v_at
it	inner <tag> </tag> block	v_it
a<	a <> block (with <>)	v_a<
i<	inner <> block	v_i<
a[	a [] block (with [])	v_a[
i[	inner [] block	v_i[
a"	a double quoted string (with quotes)	v_aquote
i"	inner double quoted string	v_iquote
a'	a single quoted string (with quotes)	v_a'
i'	inner simple quoted string	v_i'
a`	a string in backticks (with backticks)	v_a`
i`	inner string in backticks	v_i`

Additionally the following commands can be used:

:	start Ex command for highlighted lines (1)	v_:
r	change (4)	v_r
s	change	v_s
C	change (2)(4)	v_C
S	change (2)	v_S
R	change (2)	v_R
x	delete	v_x
D	delete (3)	v_D
X	delete (2)	v_X
Y	yank (2)	v_Y
p	put	v_p
P	put without overwriting registers	v_P
J	join (1)	v_J
U	make uppercase	v_U

u	make lowercase	v_u
^]	find tag	v_CTRL-]
I	block insert	v_b_I
A	block append	v_b_A

(1): Always whole lines, see :visual example.
(2): Whole lines when not using CTRL-V.
(3): Whole lines when not using CTRL-V, delete until the end of the line when
     using CTRL-V.
(4): When using CTRL-V operates on the block only.

Note that the ":vmap" command can be used to specifically map keys in Visual
mode. For example, if you would like the "/" command not to extend the Visual
area, but instead take the highlighted text and search for that:

```
:vmap / y/<C-R>"<CR>
```

(In the <> notation <>, when typing it you should type it literally; you
need to remove the 'B' flag from 'cpoptions'.)

If you want to give a register name using the """ command, do this just before
typing the operator character: "v{move-around}"xd".

If you want to give a count to the command, do this just before typing the
operator character: "v{move-around}3>" (move lines 3 indents to the right).

{move-around}

The {move-around} is any sequence of movement commands. Note the difference
with {motion}, which is only ONE movement command.

Another way to operate on the Visual area is using the /\%V item in a
pattern. For example, to replace all '(' in the Visual area with '#':

```
:'<,'>s/\%V(/#/g
```

Note that the "'<,'>" will appear automatically when you press ":" in Visual
mode.

5. Blockwise operators blockwise-operators

Reminder: Use 'virtualedit' to be able to select blocks that start or end
after the end of a line or halfway through a tab.

Visual-block Insert v_b_I

With a blockwise selection, I{string}<ESC> will insert {string} at the start
of block on every line of the block, provided that the line extends into the
block. Thus lines that are short will remain unmodified. TABs are split to
retain visual columns. Works only for adding text to a line, not for
deletions. See v_b_I_example.

Visual-block Append v_b_A

With a blockwise selection, A{string}<ESC> will append {string} to the end of
block on every line of the block. There is some differing behavior where the
block RHS is not straight, due to different line lengths:

1. Block was created with <C-v>$

   In this case the string is appended to the end of each line.
2. Block was created with <C-v>{move-around}

   In this case the string is appended to the end of the block on each line,
   and whitespace is inserted to pad to the end-of-block column.

See v_b_A_example.
Note: "I" and "A" behave differently for lines that don't extend into the
selected block. This was done intentionally, so that you can do it the way
you want.
Works only for adding text to a line, not for deletions.

Visual-block change v_b_c

All selected text in the block will be replaced by the same text string. When
using "c" the selected text is deleted and Insert mode started. You can then
enter text (without a line break). When you hit <Esc>, the same string is
inserted in all previously selected lines.

Visual-block Change v_b_C

Like using "c", but the selection is extended until the end of the line for
all lines.

v_b_<

Visual-block Shift v_b_>

The block is shifted by 'shiftwidth'. The RHS of the block is irrelevant.
The LHS of the block determines the point from which to apply a right shift,
and padding includes TABs optimally according to 'ts' and 'et'. The LHS of
the block determines the point up to which to shift left.

See v_b_>_example.
See v_b_<_example.

Visual-block Replace v_b_r

Every screen char in the highlighted region is replaced with the same char, ie
TABs are split and the virtual whitespace is replaced, maintaining screen
layout.
See v_b_r_example.

6. Repeating visual-repeat

Repeating a Visual operation works "semantically": . replays the captured
keysequence (Visual selection plus operator) at the cursor: "viwd" then "."
deletes the word at the cursor, whatever its size. (**Note:** this is unlike Vim,
where Visual-repeat works on the same fixed-size region. If you prefer that
behavior, see visual-fixed-size.)

A [count] given to "." is prepended to the replayed keys. If the selection was
extended by a command that cannot be replayed (mouse, search, Ex command,
scroll), or used gv (e.g. a mapping like ">gv"), "." instead applies the
operator to a same-size area, as if "1v" (v) preceded it.

visual-fixed-size

Example: To mimic Vim's fixed-size Visual dot-repeat: after a Visual
operation, reselect the fixed-size region ("1v", v) and applies the
operator:

```
local vop ---@type string?
vim.api.nvim_create_autocmd('CmdAtom', {
  ---@param ev {data: vim.event.cmdatom.data}
  callback = function(ev)
    if ev.data.type == 'visual' then
      vop = ev.data.atoms and ev.data.atoms[#ev.data.atoms].keys or nil
    elseif ev.data.changed then
      vop = nil  -- the last change is no longer the Visual one
    end
  end,
})
vim.keymap.set('n', '.', function()
  vim.schedule(function()
    vim.api.nvim_feedkeys(vop and ('1v' .. vop) or '.', 'n', false)
  end)
end)
```

The Visual mode default-mappings "@" repeats a register for all selected
lines if the selection is linewise. See v_@-default for details. For
example, given the text:

```
        123(hello)321
        456(world)654
        456(NOT THIS)654
```

With register "x" containing the commands yi(VP, visually selecting the
first two lines and typing @x produces:

```
        hello
        world
        456(NOT THIS)654
```

7. Examples visual-examples

:visual_example

Currently the ":" command works on whole lines only. When you select part of
a line, doing something like ":!date" will replace the whole line. If you
want only part of the line to be replaced you will have to make a mapping for
it. In a future release ":" may work on partial lines.

Here is an example, to replace the selected text with the output of "date":

```
:vmap _a <Esc>`>a<CR><Esc>`<i<CR><Esc>!!date<CR>kgJgJ
```

(In the <> notation <>, when typing it you should type it literally; you
need to remove the 'B' flag from 'cpoptions')

What this does is:

```
<Esc>           stop Visual mode
`>              go to the end of the Visual area
a<CR><Esc>      break the line after the Visual area
`<              jump to the start of the Visual area
i<CR><Esc>      break the line before the Visual area
!!date<CR>      filter the Visual text through date
kJJ             Join the lines back together
```

visual-search

Here is an idea for a mapping that makes it possible to do a search for the
selected text:

```
:vmap X y/<C-R>"<CR>
```

(In the <> notation <>, when typing it you should type it literally; you
need to remove the 'B' flag from 'cpoptions')

Note that special characters (like '.' and "*") will cause problems.

Visual-block Examples blockwise-examples

With the following text, I will indicate the commands to produce the block and
the results below. In all cases, the cursor begins on the 'a' in the first
line of the test text.
The following modeline settings are assumed ":ts=8:sw=4:".

It will be helpful to
:set hls
/<TAB>
where <TAB> is a real TAB. This helps visualise the operations.

The test text is:

```
abcdefghijklmnopqrstuvwxyz
abc             defghijklmnopqrstuvwxyz
abcdef  ghi             jklmnopqrstuvwxyz
abcdefghijklmnopqrstuvwxyz
```

1. fo<C-v>3jISTRING<ESC> v_b_I_example

```
abcdefghijklmnSTRINGopqrstuvwxyz
abc           STRING  defghijklmnopqrstuvwxyz
abcdef  ghi   STRING    jklmnopqrstuvwxyz
abcdefghijklmnSTRINGopqrstuvwxyz
```

abc                         defghijklmnopqrstuvwxyz
abcdef  ghi                         jklmnopqrstuvwxyz
abcdefghijklmn            opqrstuvwxyz
```

1. fo<C-v>5l3jrX v_b_r_example

```
abcdefghijklmnXXXXXXuvwxyz
abc           XXXXXXhijklmnopqrstuvwxyz
abcdef  ghi   XXXXXX    jklmnopqrstuvwxyz
abcdefghijklmnXXXXXXuvwxyz
```

8. Select mode Select Select-mode

Select mode looks like Visual mode, but the commands accepted are quite
different. This resembles the selection mode in Microsoft Windows.
When the 'showmode' option is set, "-- SELECT --" is shown in the last line.

Entering Select mode:

- Using the mouse to select an area, and 'selectmode' contains "mouse".

  'mouse' must also contain a flag for the current mode.
- Using a non-printable movement command, with the Shift key pressed, and

  'selectmode' contains "key". For example: <S-Left> and <S-End>. 'keymodel'
  must also contain "startsel".
- Using "v", "V" or CTRL-V command, and 'selectmode' contains "cmd".

- Using "gh", "gH" or "g_CTRL-H" command in Normal mode.

- From Visual mode, press CTRL-G. v_CTRL-G

Commands in Select mode:

- Printable characters, <NL> and <CR> cause the selection to be deleted, and
  Vim enters Insert mode. The typed character is inserted.
- Non-printable movement commands, with the Shift key pressed, extend the
  selection. 'keymodel' must include "startsel".
- Non-printable movement commands, with the Shift key NOT pressed, stop Select
  mode. 'keymodel' must include "stopsel".
- ESC stops Select mode.
- CTRL-O switches to Visual mode for the duration of one command. v_CTRL-O
- CTRL-G switches to Visual mode.
- CTRL-R {register} selects the register to be used for the text that is
  deleted when typing text. v_CTRL-R
  Unless you specify the "_" (black hole) register, the unnamed register is
  also overwritten.

Otherwise, typed characters are handled as in Visual mode.

When using an operator in Select mode, and the selection is linewise, the selected lines are operated upon, but like in charwise selection. For example, when a whole line is deleted, it can later be pasted in the middle of a line.

Mappings and menus in Select mode. Select-mode-mapping

When mappings and menus are defined with the :vmap or :vmenu command they work both in Visual mode and in Select mode. When these are used in Select mode Vim automatically switches to Visual mode, so that the same behavior as in Visual mode is effective. If you don't want this use :xmap or :smap.

One particular edge case:

```
:vnoremap <C-K> <Esc>
```

This ends Visual mode when in Visual mode, but in Select mode it does not work, because Select mode is restored after executing the mapped keys. You need to use:

```
:snoremap <C-K> <Esc>
```

Users will expect printable characters to replace the selected area. Therefore avoid mapping printable characters in Select mode. Or use :sunmap after :map and :vmap to remove it for Select mode.

After the mapping or menu finishes, the selection is enabled again and Select mode entered, unless the selected area was deleted, another buffer became the current one or the window layout was changed.

When a character was typed that causes the selection to be deleted and Insert mode started, Insert mode mappings are applied to this character. This may cause some confusion, because it means Insert mode mappings apply to a character typed in Select mode. Language mappings apply as well.

gV v_gV

gV — Avoid the automatic reselection of the Visual area after a Select mode mapping or menu has finished. Put this just before the end of the mapping or menu. At least it should be after any operations on the selection.

gh

gh — Start Select mode, charwise. This is like "v", but starts Select mode instead of Visual mode. Mnemonic: "get highlighted".

gH

gH — Start Select mode, linewise. This is like "V", but starts Select mode instead of Visual mode. Mnemonic: "get Highlighted".

g_CTRL-H

g CTRL-H — Start Select mode, blockwise. This is like CTRL-V, but starts Select mode instead of Visual mode. Mnemonic: "get Highlighted".

Predefined variables v:var v:

Most variables are read-only, when a variable can be set by the user, it will
be mentioned at the variable description below. The type cannot be changed.

v:argf argf-variable

v:argf
File arguments (expanded to absolute paths) given at startup.

Unlike v:argv, this does not include option arguments such as -u, --cmd, or +cmd. Unlike argv(), it is not affected by later :args, :argadd, or plugin modifications.

Example:

```
nvim file1.txt +ls -- file2.txt
:echo v:argf
" ['/path/to/cwd/file1.txt', '/path/to/cwd/file2.txt']
```

v:argv argv-variable

v:argv
Command line arguments (-u, --cmd, +cmd, …) Nvim was invoked with. The first item is the Nvim command.

See v:progpath to get the full path to Nvim.
See v:argf to get only file args, without other options.

v:cascading cascading-variable

v:cascading
v:true during multicursor cascade, v:false otherwise.
Read-only.

v:char char-variable

v:char
Argument for evaluating 'formatexpr' and used for the typed character when using <expr> in an abbreviation :map-<expr>.
It is also used by the InsertCharPre, InsertEnter, CmdlineLeave and CmdlineLeavePre events.

v:charconvert_from charconvert_from-variable

v:charconvert_from
The name of the character encoding of a file to be converted.
Only valid while evaluating the 'charconvert' option.

v:charconvert_to charconvert_to-variable

v:charconvert_to
The name of the character encoding of a file after conversion.
Only valid while evaluating the 'charconvert' option.

v:cmdarg cmdarg-variable

v:cmdarg
The extra arguments ("++p", "++enc=", "++ff=") given to a file read/write command. This is set before an autocommand event for a file read/write command is triggered. There is a leading space to make it possible to append this variable directly after the read/write command. **Note:** "+cmd" isn't included here, because it will be executed anyway.

v:cmdbang cmdbang-variable

v:cmdbang
Set like v:cmdarg for a file read/write command. When a "!" was used the value is 1, otherwise it is 0. Note that this can only be used in autocommands. For user commands <bang> can be used.

v:collate collate-variable

v:collate
The current locale setting for collation order of the runtime environment. This allows Vim scripts to be aware of the current locale encoding. Technical: it's the value of LC_COLLATE. When not using a locale the value is "C".
This variable can not be set directly, use the :language command.
See multi-lang.

v:completed_item completed_item-variable

v:completed_item
Dictionary containing the complete-items for the most recently completed word after CompleteDone. Empty if the completion failed, or after leaving and re-entering insert mode.
Note: Plugins can modify the value to emulate the builtin CompleteDone event behavior.

v:count count-variable

v:count
The count given for the last Normal mode command. Can be used to get the count before a mapping. Read-only. Example:

```
:map _x :<C-U>echo "the count is " .. v:count<CR>
```

Note: The <C-U> is required to remove the line range that you get when typing ':' after a count.
When there are two counts, as in "3d2w", they are multiplied, just like what happens in the command, "d6w" for the example.
Also used for evaluating the 'formatexpr' option.

v:count1 count1-variable

v:count1
Just like "v:count", but defaults to one when no count is used.

v:ctype ctype-variable

v:ctype
The current locale setting for characters of the runtime environment. This allows Vim scripts to be aware of the current locale encoding. Technical: it's the value of LC_CTYPE. When not using a locale the value is "C". This variable can not be set directly, use the :language command.
See multi-lang.

v:dying dying-variable

v:dying
Normally zero. When a deadly signal is caught it's set to one. When multiple signals are caught the number increases. Can be used in an autocommand to check if Vim didn't terminate normally.
Example:

```
:au VimLeave * if v:dying | echo "\nAAAAaaaarrrggghhhh!!!\n" | endif
```

Note: if another deadly signal is caught when v:dying is one, VimLeave autocommands will not be executed.

v:echospace echospace-variable

v:echospace
Number of screen cells that can be used for an :echo message in the last screen line before causing the hit-enter prompt (no longer applicable when ui2 is enabled).

Depends on 'showcmd', 'ruler' and 'columns'. You need to check 'cmdheight' for whether there are full-width lines available above the last line.

v:errmsg errmsg-variable

v:errmsg
Last error message that occurred (not necessarily displayed). Modifiable (can be set).
Example:

```
let v:errmsg = ""
silent! next
if v:errmsg != ""
  " ... handle error
```

v:errors errors-variable assert-return

v:errors
Errors found by assert functions, such as assert_true().
This is a list of strings.
The assert functions append an item when an assert fails.
The return value indicates this: a one is returned if an item was added to v:errors, otherwise zero is returned.
To remove old results make it empty:

```
let v:errors = []
```

If v:errors is set to anything but a list it is made an empty list by the assert function.

v:event event-variable

v:event
Dictionary of event data for the current autocommand. Valid only during the event lifetime; storing or passing v:event is invalid! Copy it instead:

```
au TextYankPost * let g:foo = deepcopy(v:event)
```

Keys vary by event; see the documentation for the specific event, e.g. DirChanged or TextYankPost.

KEY	DESCRIPTION
abort	Whether the event triggered during an aborting condition (e.g. c_Esc or c_CTRL-C for CmdlineLeave).
chan	channel-id
changed_window	Is v:true if the event fired while changing window (or tab) on DirChanged.
cmdlevel	Level of cmdline.
cmdtype	Type of cmdline, cmdline-char.
col	Column count of popup menu on CompleteChanged, relative to screen.
complete_type	See complete_info_mode
complete_word	The selected word, or empty if completion was abandoned/discarded.
completed_item	Current selected item on CompleteChanged, or {} if no item selected.
cwd	Current working directory.
height	Height of popup menu on CompleteChanged
inclusive	Motion is inclusive, else exclusive.
info	Dict of arbitrary event data.

operator Current operator. Also set for Ex commands (unlike v:operator). For example if TextYankPost is triggered by the :yank Ex command then v:event.operator is "y".
reason CompleteDone reason.
regcontents Text stored in the register as a readfile()-style list of lines.
regname Requested register (e.g "x" for "xyy), or empty string for an unnamed operation.
regtype Type of register as returned by getregtype().
row Row count of popup menu on CompleteChanged, relative to screen.
scope Event-specific scope name.
scrollbar v:true if popup menu has a scrollbar, or v:false if not.
size Total number of completion items on CompleteChanged.
status Job status or exit code, -1 means "unknown". TermClose
visual Selection is visual (as opposed to e.g. a motion range).
width Width of popup menu on CompleteChanged
windows List of window IDs that changed on WinResized

v:exception exception-variable

v:exception

The value of the exception most recently caught and not finished. See also v:stacktrace, v:throwpoint, and throw-variables.
Example:

```
try
  throw "oops"
catch /.*/
  echo "caught " .. v:exception
endtry
```

Output: "caught oops".

v:exiting exiting-variable

v:exiting

Exit code, or v:null before invoking the VimLeavePre and VimLeave autocmds. See :q, :x and :cquit.
Example:

```
:au VimLeave * echo "Exit code is " .. v:exiting
```

v:exitreason exitreason-variable

v:exitreason

Reason for the current exit. Set before QuitPre. Reset if exit was canceled.

Possible values:

- "" Not exiting, or exit was canceled.
- "quit" :quit, :qall, :wq, ZZ, ZQ, etc.
- "restart" :restart, ZR.
- "restart!" :restart!, [count]ZR.

Example:

```
autocmd ExitPre * if v:exitreason ==# 'restart' | echomsg 'restarting' | endif
```

Read-only.

v:false false-variable

v:false

Special value used to put "false" in JSON and msgpack. See json_encode(). This value is converted to "v:false" when used as a String (e.g. in expr5 with string concatenation operator) and to zero when used as a Number (e.g. in expr5 or expr7 when used with numeric operators). Read-only.

v:fcs_choice fcs_choice-variable

v:fcs_choice

What should happen after a FileChangedShell event was triggered. Can be used in an autocommand to tell Vim what to do with the affected buffer:
reload Reload the buffer (does not work if the file was deleted).
edit Reload the buffer and detect the values for options such as 'fileformat', 'fileencoding', 'binary' (does not work if the file was deleted).
ask Ask the user what to do, as if there

was no autocommand. Except that when
only the timestamp changed nothing
will happen.
<empty> Nothing, the autocommand should do
everything that needs to be done.
The default is empty. If another (invalid) value is used then
Vim behaves like it is empty, there is no warning message.

v:fcs_reason fcs_reason-variable

v:fcs_reason

The reason why the FileChangedShell event was triggered.
Can be used in an autocommand to decide what to do and/or what
to set v:fcs_choice to. Possible values:

- deleted file no longer exists
- conflict file contents, mode or timestamp was changed and buffer is modified
- changed file contents has changed
- mode mode of file changed
- time only file timestamp changed

v:fname fname-variable

v:fname

When evaluating 'includeexpr': the file name that was
detected. Empty otherwise.

v:fname_diff fname_diff-variable

v:fname_diff

The name of the diff (patch) file. Only valid while
evaluating 'patchexpr'.

v:fname_in fname_in-variable

v:fname_in

The name of the input file. Valid while evaluating:

option	used for
'charconvert'	file to be converted
'diffexpr'	original file
'patchexpr'	original file

And set to the swap file name for SwapExists.

v:fname_new fname_new-variable

v:fname_new

The name of the new version of the file. Only valid while
evaluating 'diffexpr'.

v:fname_out fname_out-variable

v:fname_out

The name of the output file. Only valid while
evaluating:

option	used for
'charconvert'	resulting converted file [1]
'diffexpr'	output of diff
'patchexpr'	resulting patched file

[1] When doing conversion for a write command (e.g., ":w
file") it will be equal to v:fname_in. When doing conversion
for a read command (e.g., ":e file") it will be a temporary
file and different from v:fname_in.

v:folddashes folddashes-variable

v:folddashes

Used for 'foldtext': dashes representing foldlevel of a closed
fold.
Read-only in the sandbox. fold-foldtext

v:foldend foldend-variable

v:foldend

Used for 'foldtext': last line of closed fold.
Read-only in the sandbox. fold-foldtext

v:foldlevel foldlevel-variable

v:foldlevel

Used for 'foldtext': foldlevel of closed fold.
Read-only in the sandbox. fold-foldtext

v:foldstart foldstart-variable

v:foldstart

Used for 'foldtext': first line of closed fold.
Read-only in the sandbox. fold-foldtext

v:hlsearch hlsearch-variable

v:hlsearch

Variable that indicates whether search highlighting is on.
Setting it makes sense only if 'hlsearch' is enabled. Setting
this variable to zero acts like the :nohlsearch command,
setting it to one acts like

```
let &hlsearch = &hlsearch
```

Note that the value is restored when returning from a
function. function-search-undo.

v:insertmode insertmode-variable

v:insertmode
Used for the InsertEnter and InsertChange autocommand
events. Values:
i Insert mode
r Replace mode
v Virtual Replace mode

v:key key-variable

v:key
Key of the current item of a Dictionary. Only valid while
evaluating the expression used with map() and filter().
Read-only.

v:lang lang-variable

v:lang
The current locale setting for messages of the runtime
environment. This allows Vim scripts to be aware of the
current language. Technical: it's the value of LC_MESSAGES.
The value is system dependent.
This variable can not be set directly, use the :language
command.
It can be different from v:ctype when messages are desired
in a different language than what is used for character
encoding. See multi-lang.

v:lc_time lc_time-variable

v:lc_time
The current locale setting for time messages of the runtime
environment. This allows Vim scripts to be aware of the
current language. Technical: it's the value of LC_TIME.
This variable can not be set directly, use the :language
command. See multi-lang.

v:lnum lnum-variable

v:lnum
Line number for the 'foldexpr' fold-expr, 'formatexpr',
'indentexpr' and 'statuscolumn' expressions, tab page number
for 'guitablabel' and 'guitabtooltip'. Only valid while one of
these expressions is being evaluated. Read-only when in the
sandbox.

v:lua lua-variable

v:lua
Prefix for calling Lua functions from expressions.
See v:lua-call for more information.

v:maxcol maxcol-variable

v:maxcol
Maximum line length. Depending on where it is used it can be
screen columns, characters or bytes. The value currently is
2147483647 on all systems.

v:mouse_col mouse_col-variable

v:mouse_col
Column number for a mouse click obtained with getchar().
This is the screen column number, like with virtcol(). The
value is zero when there was no mouse button click.

v:mouse_lnum mouse_lnum-variable

v:mouse_lnum
Line number for a mouse click obtained with getchar().
This is the text line number, not the screen line number. The
value is zero when there was no mouse button click.

v:mouse_win mouse_win-variable

v:mouse_win
Window number for a mouse click obtained with getchar().
First window has number 1, like with winnr(). The value is
zero when there was no mouse button click.

v:mouse_winid mouse_winid-variable

v:mouse_winid
window-ID for a mouse click obtained with getchar().
The value is zero when there was no mouse button click.

v:msgpack_types msgpack_types-variable

v:msgpack_types
Dictionary containing msgpack types used by msgpackparse()
and msgpackdump(). All types inside dictionary are fixed
(not editable) empty lists. To check whether some list is one
of msgpack types, use is operator.

v:null null-variable

v:null
Special value used to put "null" in JSON and NIL in msgpack.
See json_encode(). This value is converted to "v:null" when
used as a String (e.g. in expr5 with string concatenation
operator) and to zero when used as a Number (e.g. in expr5
or expr7 when used with numeric operators). Read-only.
In some places v:null can be used for a List, Dict, etc.
that is not set. That is slightly different than an empty
List, Dict, etc.

v:numbermax numbermax-variable
v:numbermax Maximum value of a number.

v:numbermin numbermin-variable
v:numbermin Minimum value of a number (negative).

v:numbersize numbersize-variable
v:numbersize
Number of bits in a Number. This is normally 64, but on some systems it may be 32.

v:oldfiles oldfiles-variable
v:oldfiles
List of file names that is loaded from the shada file on startup. These are the files that Vim remembers marks for. The length of the List is limited by the ' argument of the 'shada' option (default is 100).
When the shada file is not used the List is empty.
Also see :oldfiles and c_#<.
The List can be modified, but this has no effect on what is stored in the shada file later. If you use values other than String this will cause trouble.

v:operator operator-variable
v:operator
The last operator given in Normal mode. This is a single character except for commands starting with <g> or <z>, in which case it is two characters. Best used alongside v:prevcount and v:register. Useful if you want to cancel Operator-pending mode and then use the operator, e.g.:

```
:omap O <Esc>:call MyMotion(v:operator)<CR>
```

The value remains set until another operator is entered, thus don't expect it to be empty.
v:operator is not set for :delete, :yank or other Ex commands.
Read-only.

v:option_command option_command-variable
v:option_command
Command used to set the option. Valid while executing an OptionSet autocommand.

value	option was set via
"setlocal"	:setlocal or :let l:xxx
"setglobal"	:setglobal or :let g:xxx
"set"	:set or :let
"modeline"	modeline

v:option_new option_new-variable
v:option_new
New value of the option. Valid while executing an OptionSet autocommand.

v:option_old option_old-variable
v:option_old
Old value of the option. Valid while executing an OptionSet autocommand. Depending on the command used for setting and the kind of option this is either the local old value or the global old value.

v:option_oldglobal option_oldglobal-variable
v:option_oldglobal
Old global value of the option. Valid while executing an OptionSet autocommand.

v:option_oldlocal option_oldlocal-variable
v:option_oldlocal
Old local value of the option. Valid while executing an OptionSet autocommand.

v:option_type option_type-variable
v:option_type
Scope of the set command. Valid while executing an OptionSet autocommand. Can be either "global" or "local"

v:prevcount prevcount-variable
v:prevcount
The count given for the last but one Normal mode command. This is the v:count value of the previous command. Useful if you want to cancel Visual or Operator-pending mode and then use the count, e.g.:

```
:vmap % <Esc>:call MyFilter(v:prevcount)<CR>
```

Read-only.

v:profiling profiling-variable
v:profiling
Normally zero. Set to one after using ":profile start".
See profiling.

v:progname progname-variable
v:progname
The name by which Nvim was invoked (with path removed).
Read-only.

v:progpath progpath-variable

v:progpath
Absolute path to the current running Nvim.
Read-only.

v:register register-variable

v:register
The name of the register in effect for the current normal mode command (regardless of whether that command actually used a register). Or for the currently executing normal mode mapping (use this in custom commands that take a register).
If none is supplied it is the default register '"', unless 'clipboard' contains "unnamed" or "unnamedplus", then it is "*" or '+'.
Also see getreg() and setreg()

v:relnum relnum-variable

v:relnum
Relative line number for the 'statuscolumn' expression.
Read-only.

v:scrollstart scrollstart-variable

v:scrollstart
String describing the script or function that caused the screen to scroll up. It's only set when it is empty, thus the first reason is remembered. It is set to "Unknown" for a typed command.

v:searchforward searchforward-variable

v:searchforward
Search direction: 1 after a forward search, 0 after a backward search. It is reset to forward when directly setting the last search pattern, see quote/.
Note that the value is restored when returning from a function. function-search-undo.
Read-write.

v:servername servername-variable

v:servername
Primary listen-address of Nvim, the first item returned by serverlist(). Usually this is the named pipe created by Nvim at startup or given by --listen (or the deprecated $NVIM_LISTEN_ADDRESS env var).

See also serverstart() serverstop().
Read-only.

$NVIM

$NVIM is set to v:servername by terminal and jobstart(), and is thus a hint that the current environment is a child (direct subprocess) of Nvim.

Example: a child Nvim process can detect and make requests to its parent Nvim:

```
if vim.env.NVIM then
  local ok, chan = pcall(vim.fn.sockconnect, 'pipe', vim.env.NVIM, {rpc=true})
  if ok and chan then
    local client = vim.api.nvim_get_chan_info(chan).client
    local rv = vim.rpcrequest(chan, 'nvim_exec_lua', [[return ... + 1]], { 41 })
    vim.print(('got "%s" from parent Nvim'):format(rv))
  end
end
```

v:shell_error shell_error-variable

v:shell_error
Result of the last shell command. When non-zero, the last shell command had an error. When zero, there was no problem. This only works when the shell returns the error code to Vim. The value -1 is often used when the command could not be executed. Read-only.
Example:

```
!mv foo bar
if v:shell_error
  echo 'could not rename "foo" to "bar"!'
endif
```

v:stacktrace stacktrace-variable

v:stacktrace
The stack trace of the exception most recently caught and not finished. Refer to getstacktrace() for the structure of stack trace. See also v:exception, v:throwpoint, and throw-variables.

v:startreason startreason-variable

v:startreason
The reason Nvim started. Possible values:

- "normal" Normal startup, yearning for life, etc.
- "restart" Started by :restart.

- "restart!" Started by :restart!.

Read-only.

v:starttime starttime-variable

v:starttime
Timestamp (nanoseconds since UNIX epoch) when the Nvim process started.

To see the current "uptime":

```
vim.print(('uptime: %d seconds'):format(os.time() - (vim.v.starttime / 1e9)))
```

Read-only.

v:statusmsg statusmsg-variable

v:statusmsg
Last given status message.
Modifiable (can be set).

v:stderr stderr-variable

v:stderr
channel-id corresponding to stderr. The value is always 2; use this variable to make your code more descriptive. Unlike stdin and stdout (see stdioopen()), stderr is always open for writing. Example:

```
:call chansend(v:stderr, "error: toaster empty\n")
```

v:swapchoice swapchoice-variable

v:swapchoice
SwapExists autocommands can set this to the selected choice for handling an existing swapfile:

```
'o'    Open read-only
'e'    Edit anyway
'r'    Recover
'd'    Delete swapfile
'q'    Quit
'a'    Abort
```

The value should be a single-character string. An empty value results in the user being asked, as would happen when there is no SwapExists autocommand. The default is empty.

v:swapcommand swapcommand-variable

v:swapcommand
Normal mode command to be executed after a file has been opened. Can be used for a SwapExists autocommand to have another Vim open the file and jump to the right place. For example, when jumping to a tag the value is ":tag tagname\r". For ":edit +cmd file" the value is ":cmd\r".

v:swapname swapname-variable

v:swapname
Name of the swapfile found.
Only valid during SwapExists event.
Read-only.

v:t_blob t_blob-variable v:t_TYPE

v:t_blob Value of Blob type. Read-only. See: type()

v:t_bool t_bool-variable

v:t_bool Value of Boolean type. Read-only. See: type()

v:t_dict t_dict-variable

v:t_dict Value of Dictionary type. Read-only. See: type()

v:t_float t_float-variable

v:t_float Value of Float type. Read-only. See: type()

v:t_func t_func-variable

v:t_func Value of Funcref type. Read-only. See: type()

v:t_list t_list-variable

v:t_list Value of List type. Read-only. See: type()

v:t_number t_number-variable

v:t_number Value of Number type. Read-only. See: type()

v:t_string t_string-variable

v:t_string Value of String type. Read-only. See: type()

v:termrequest termrequest-variable

v:termrequest
The value of the most recent OSC, DCS or APC control sequence sent from a process running in the embedded terminal. This can be read in a TermRequest event handler to respond to queries from embedded applications.

v:termresponse termresponse-variable

v:termresponse
The most recent OSC, DCS, APC, or recognized CSI (DA1, kitty multiple-cursors) control sequence received by Nvim from the host-terminal. Can be read in a TermResponse event handler after querying the terminal.

v:testing testing-variable

v:testing Must be set before using test_garbagecollect_now().

v:this_session this_session-variable
v:this_session
Full filename of the last loaded or saved session file.
Empty when no session file has been saved. See :mksession.
Modifiable (can be set).

v:throwpoint throwpoint-variable
v:throwpoint
The point where the exception most recently caught and not
finished was thrown. Not set when commands are typed. See
also v:exception, v:stacktrace, and throw-variables.
Example:

```
try
  throw "oops"
catch /.*/
  echo "Exception from" v:throwpoint
endtry
```

Output: "Exception from test.vim, line 2"

v:true true-variable
v:true
Special value used to put "true" in JSON and msgpack. See
json_encode(). This value is converted to "v:true" when used
as a String (e.g. in expr5 with string concatenation
operator) and to one when used as a Number (e.g. in expr5 or
expr7 when used with numeric operators). Read-only.

v:useractive useractive-variable user-idle
v:useractive
Timestamp (nanoseconds since UNIX epoch) indicating the most
recent user activity, i.e. when a key is received from a UI
(TUI input or nvim_input()).

Initialized to 0 (no user activity since startup).
Read-only.

v:val val-variable
v:val
Value of the current item of a List or Dictionary. Only
valid while evaluating the expression used with map() and
filter(). Read-only.

v:version version-variable
v:version
Vim version number: major version times 100 plus minor
version. Vim 5.0 is 500, Vim 5.1 is 501.
Read-only.
Use has() to check the Nvim (not Vim) version:

```
:if has("nvim-0.2.1")
```

v:versionlong versionlong-variable
v:versionlong
Like v:version, but also including the patchlevel in the last
four digits. Version 8.1 with patch 123 has value 8010123.
This can be used like this:

```
if v:versionlong >= 8010123
```

However, if there are gaps in the list of patches included
this will not work well. This can happen if a recent patch
was included into an older version, e.g. for a security fix.
Use the has() function to make sure the patch is actually
included.

v:vim_did_enter vim_did_enter-variable
v:vim_did_enter
0 during startup, 1 just before VimEnter.
See also v:vim_did_init, which is set earlier.
Read-only.

v:vim_did_init vim_did_init-variable
v:vim_did_init
0 during initialization, 1 after sourcing the user vimrc,
just before load-plugins.
See also v:vim_did_enter, which is set later.
Read-only.

v:virtnum virtnum-variable
v:virtnum
Virtual line number for the 'statuscolumn' expression.
Negative when drawing the status column for virtual lines, zero
when drawing an actual buffer line, and positive when drawing
the wrapped part of a buffer line.
Read-only.

v:warningmsg warningmsg-variable
v:warningmsg
Last given warning message.
Modifiable (can be set).

v:windowid windowid-variable
v:windowid
Application-specific window "handle" which may be set by any

attached UI. Defaults to zero.
Note: For Nvim windows use winnr() or win_getid(), see
window-ID.

Editing with multiple windows and buffers. buffers

The commands which have been added to use multiple windows and buffers are explained here. Additionally, there are explanations for commands that work differently when used in combination with more than one window.

The basics are explained in chapter 7 and 8 of the user manual usr_07.txt usr_08.txt.

1. Introduction windows-intro window

Summary:
A buffer is the in-memory text of a file.
A window is a viewport on a buffer.
A tabpage is a collection of windows.

A window is a viewport onto a buffer. You can use multiple windows on one buffer, or several windows on different buffers.

A buffer is a file loaded into memory for editing. The original file remains unchanged until you write the buffer to the file.

A buffer can be in one of three states:

active-buffer

active: The buffer is displayed in a window. If there is a file for this buffer, it has been read into the buffer. The buffer may have been modified since then and thus be different from the file.

hidden-buffer

hidden: The buffer is not displayed. If there is a file for this buffer, it has been read into the buffer. Otherwise it's the same as an active buffer, you just can't see it.

inactive-buffer

inactive: The buffer is not displayed and does not contain anything. Options for the buffer are remembered if the file was once loaded. It can contain marks from the shada file. But the buffer doesn't contain text.

In a table:

state	displayed	loaded	":buffers"
in window shows			
active	yes	yes	'a'
hidden	no	yes	'h'
inactive	no	no	' '

buffer-reuse

Each buffer has a unique number and the number will not change within a Vim session. The bufnr() and bufname() functions can be used to convert between a buffer name and the buffer number. There is one exception: if a new empty buffer is created and it is not modified, the buffer will be re-used when loading another file into that buffer. This also means the buffer number will not change.

The main Vim window can hold several split windows. There are also tabpages, each of which can hold multiple windows.

focusable

If a window is focusable, it is part of the "navigation stack", that is, editor commands such as :windo, CTRL-W, etc., will consider the window as one that can be made the "current window". A non-focusable window will be skipped by such commands as it isn't assigned a window number. It can be explicitly focused by nvim_set_current_win(), because it is still assigned a window-ID. If it is focused, it will also have a window number. Non-focusable windows are not listed by :tabs, or counted by the default 'tabline'. Their buffer content is not included in 'complete' "w" completion.

Windows (especially floating windows) can have many other api-win_config properties such as "hide" and "fixed" which also affect behavior.

window-hidden

If the api-win_config hide flag is set, then the window is "hidden": it exists but is not shown anywhere. Hidden windows may be focused (the cursor may enter it), so the cursor can perform actions in it, but the cursor will be invisible. Hidden windows and their statuslines are not redrawn.

window-ID winid windowid

Each window has a unique identifier called the window ID, which is permanent during the Nvim session. The win_getid() and win_id2tabwin() functions convert between the window/tab "number" and the identifier.

window-number

Windows are numbered according to their arrangement in a tabpage; this window "number" is given by winnr() and may change whenever windows are opened or closed. The window number is only valid in one specific tab, whereas the window ID is valid globally, across tabs. For most functions that take a window ID or a window number, the window number only applies to the current tab, while the window ID can refer to a window in any tab.

2. Starting Vim windows-starting

By default, Vim starts with one window, just like Vi.

The "-o" and "-O" arguments to Vim can be used to open a window for each file in the argument list. The "-o" argument will split the windows horizontally; the "-O" argument will split the windows vertically. If both "-o" and "-O" are given, the last one encountered will be used to determine the split orientation. For example, this will open three windows, split horizontally:

```
vim -o file1 file2 file3
```

"-oN", where N is a decimal number, opens N windows split horizontally. If there are more file names than windows, only N windows are opened and some files do not get a window. If there are more windows than file names, the last few windows will be editing empty buffers. Similarly, "-ON" opens N windows split vertically, with the same restrictions.

If there are many file names, the windows will become very small. You might want to set the 'winheight' and/or 'winwidth' options to create a workable situation.

Buf/Win Enter/Leave autocommands are not executed when opening the new windows and reading the files, that's only done when they are really entered.

status-line

A status line will be used to separate windows. The 'laststatus' option tells when the last window also has a status line:

'laststatus' = 0	never a status line
'laststatus' = 1	status line if there is more than one window
'laststatus' = 2	always a status line
'laststatus' = 3	have a global statusline at the bottom instead of one for each window

You can change the contents of the status line with the 'statusline' option. This option can be local to the window, so that you can have a different status line in each window.

Normally, inversion is used to display the status line. This can be changed with the hl-StatusLine highlight group. If no highlighting is used for the status line, the '^' character is used for the current window, and '=' for other windows. If 'mouse' is enabled, a status line can be dragged to resize windows.

filler-lines

The lines after the last buffer line in a window are called filler lines. By default, these lines start with a tilde (~) character. The "eob" item in the 'fillchars' option can be used to change this character. By default, these characters are highlighted as NonText (hl-NonText). The EndOfBuffer highlight group (hl-EndOfBuffer) can be used to change the highlighting of the filler characters.

3. Opening and closing a window opening-window

CTRL-W s CTRL-W_s

CTRL-W S CTRL-W_S

CTRL-W CTRL-S CTRL-W_CTRL-S

:[N]sp[lit] [++opt] [+cmd] :sp :split

Split current window in two. The result is two viewports on the same file.

Make the new window N high (default is to use half the height of the current window). Reduces the current window height to create room (and others, if the 'equalalways' option is set, 'eadirection' isn't "hor", and one of them is higher than the current or the new window).

Note: CTRL-S does not work on all terminals and might block further input, use CTRL-Q to get going again.
Also see ++opt and +cmd.

E242 E1159

Be careful when splitting a window in an autocommand, it may mess up the window layout if this happens while making other window layout changes.

:[N]sp[lit] [++opt] [+cmd] {file} :split_f

Like :split but create a new window and start editing file {file} in it.
This behaves almost like a ":split" first, and then an ":edit" command, but the alternate file name in the original window is set to {file}.
If [+cmd] is given, execute the command when the file has been loaded +cmd.
Also see ++opt.
Make new window N high (default is to use half the existing height). Reduces the current window height to create room (and others, if the 'equalalways' option is set).

CTRL-W CTRL-V CTRL-W_CTRL-V

CTRL-W v CTRL-W_v

:[N]vs[plit] [++opt] [+cmd] [file] :vs :vsplit
Like :split, but split vertically. The windows will be
spread out horizontally if
1. a width was not specified,

2. 'equalalways' is set,

3. 'eadirection' isn't "ver", and

4. one of the other windows is wider than the current or new

window.
If N was given make the new window N columns wide, if
possible.
Note: In other places CTRL-Q does the same as CTRL-V, but here
it doesn't!

CTRL-W n CTRL-W_n

CTRL-W CTRL-N CTRL-W_CTRL-N

:[N]new [++opt] [+cmd] :new

Create a new window and start editing an empty file in it.
Make new window N high (default is to use half the existing
height). Reduces the current window height to create room
(and others, if the 'equalalways' option is set and
'eadirection' isn't "hor").
Also see ++opt and +cmd.
If 'fileformats' is not empty, the first format given will be
used for the new buffer. If 'fileformats' is empty, the
'fileformat' of the current buffer is used. This can be
overridden with the ++opt argument.
Autocommands are executed in this order:
1. WinLeave for the current window

2. WinEnter for the new window

3. BufLeave for the current buffer

4. BufEnter for the new buffer

This behaves like a ":split" first, and then an ":enew"
command.

:[N]new [++opt] [+cmd] {file}
Like :split_f, create a new window and start editing {file}.

:[N]vne[w] [++opt] [+cmd] [file] :vne :vnew
Like :new, but split vertically. If 'equalalways' is set
and 'eadirection' isn't "ver" the windows will be spread out
horizontally, unless a width was specified.

:[N]sv[iew] [++opt] [+cmd] [file] :sv :sview splitview
Same as ":split", but set 'readonly' option for this buffer.

:[N]sf[ind] [++opt] [+cmd] {file} :sf :sfi :sfind splitfind
Same as ":split", but search for {file} in 'path' like in
:find. Doesn't split if {file} is not found.

CTRL-W CTRL-^ CTRL-W_CTRL-^ CTRL-W_^
CTRL-W ^ Split the current window in two and edit the alternate file.
When a count N is given, split the current window and edit
buffer N. Similar to ":sp #" and ":sp #N", but it allows the
other buffer to be unnamed. This command matches the behavior
of CTRL-^, except that it splits a window first.

CTRL-W ge CTRL-W_ge

Detach the current window as an external window.
Only available when using a UI with ui-multigrid support.

Note that the 'splitbelow' and 'splitright' options influence where a new
window will appear.

E36

Creating a window will fail if there is not enough room. Every window needs
at least one screen line and column, sometimes more. Options 'winminheight'
and 'winminwidth' are relevant.

:vert :vertical
:vert[ical] {cmd}
Execute {cmd}. If it contains a command that splits a window,

it will be split vertically. For vertical wincmd = windows
will be equalized only vertically.
Doesn't work for :execute and :normal.

:hor :horizontal
:hor[izontal] {cmd}
Execute {cmd} in a horizontal split window. Supports these
commands:

- :wincmd =: equalize windows only horizontally.

- :terminal: open a terminal buffer in a split window.

- :checkhealth: open a healthcheck buffer in a split window.

:lefta[bove] {cmd} :lefta :leftabove
:abo[veleft] {cmd} :abo :aboveleft
Execute {cmd}. If it contains a command that splits a window,
it will be opened left (vertical split) or above (horizontal
split) the current window. Overrules 'splitbelow' and
'splitright'.
Doesn't work for :execute and :normal.

:rightb[elow] {cmd} :rightb :rightbelow
:bel[owright] {cmd} :bel :belowright
Execute {cmd}. If it contains a command that splits a window,
it will be opened right (vertical split) or below (horizontal
split) the current window. Overrules 'splitbelow' and
'splitright'.
Doesn't work for :execute and :normal.

:topleft E442
:to[pleft] {cmd}
Execute {cmd}. If it contains a command that splits a window,
it will appear at the top and occupy the full width of the Vim
window. When the split is vertical the window appears at the
far left and occupies the full height of the Vim window.
Doesn't work for :execute and :normal.

:bo :botright
:bo[tright] {cmd}
Execute {cmd}. If it contains a command that splits a window,
it will appear at the bottom and occupy the full width of the
Vim window. When the split is vertical the window appears at
the far right and occupies the full height of the Vim window.
Doesn't work for :execute and :normal.

These command modifiers can be combined to make a vertically split window
occupy the full height. Example:

```
:vertical topleft split tags
```

Opens a vertically split, full-height window on the "tags" file at the far
left of the Vim window.

Closing a window

:q[uit]
:{count}q[uit] :count_quit

CTRL-W q CTRL-W_q

CTRL-W CTRL-Q CTRL-W_CTRL-Q

Without {count}: Quit the current window. If {count} is
given quit the {count} window.

edit-window

When quitting the last edit window (not counting help or
preview windows), exit Vim.

When 'hidden' is set, and there is only one window for the
current buffer, it becomes hidden. When 'hidden' is not set,
and there is only one window for the current buffer, and the
buffer was changed, the command fails.
(**Note:** CTRL-Q does not work on all terminals).
If [count] is greater than the last window number the last
window will be closed:

```
:1quit  " quit the first window
:$quit  " quit the last window
:9quit  " quit the last window
        " if there are fewer than 9 windows opened
:-quit  " quit the previous window
:+quit  " quit the next window
:+2quit " quit the second next window
```

When closing a help window, and this is not the only window,
Vim will try to restore the previous window layout, see
:helpclose.

:q[uit]!
:{count}q[uit]!
Without {count}: Quit the current window. If {count} is given quit the {count} window
If this was the last window for a buffer, any changes to that buffer are lost. When quitting the last window (not counting help windows), exit Vim. The contents of the buffer are lost, even when 'hidden' is set.

:clo[se][!]
:{count}clo[se][!]
CTRL-W c CTRL-W_c :clo :close
Without {count}: Close the current window. If given close the {count} window.

When 'hidden' is set, or when the buffer was changed and the [!] is used, the buffer becomes hidden (unless there is another window editing it).

When there is only one edit-window in the current tabpage and there is another tabpage, this closes the current tabpage.

This command fails when: E444

- There is only one window on the screen.

- When 'hidden' is not set, [!] is not used, the buffer has

changes, and there is no other window on this buffer. Changes to the buffer are not written and won't get lost, so this is a "safe" command.

CTRL-W CTRL-C CTRL-W_CTRL-C

You might have expected that CTRL-W CTRL-C closes the current window, but that does not work, because the CTRL-C cancels the command.

:hide

:hid[e]
:{count}hid[e]
Without {count}: Quit the current window, unless it is the last window on the screen.
If {count} is given quit the {count} window.

The buffer becomes hidden (unless there is another window editing it or 'bufhidden' is unload, delete or wipe).
If the window is the last one in the current tabpage the tabpage is closed.

The value of 'hidden' is irrelevant for this command.
Changes to the buffer are not written and won't get lost, so this is a "safe" command.

:hid[e] {cmd} Execute {cmd} with 'hidden' set. The previous value of 'hidden' is restored after {cmd} has been executed.
Example:

```
:hide edit Makefile
```

This will edit "Makefile", and hide the current buffer if it has any changes.

:on[ly][!]
:{count}on[ly][!]
CTRL-W o CTRL-W_o E445
CTRL-W CTRL-O CTRL-W_CTRL-O :on :only
Make the current window the only one on the screen. All other windows are closed. For {count} see the :quit command above :count_quit.

When the 'hidden' option is set, all buffers in closed windows become hidden.

When 'hidden' is not set, and the 'autowrite' option is set, modified buffers are written. Otherwise, windows that have buffers that are modified are not removed, unless the [!] is given, then they become hidden. But modified buffers are never abandoned, so changes cannot get lost.

:fc :fclose

:[count]fc[lose][!]
Close [count] floating windows with the highest zindex values.
'!' to close all floating windows.

4. Moving cursor to other windows window-move-cursor

CTRL-W <Down> CTRL-W <Down>

CTRL-W CTRL-J CTRL-W_CTRL-J CTRL-W_j
CTRL-W j Move cursor to Nth window below current one. Uses the cursor position to select between alternatives.

CTRL-W <Up> CTRL-W_<Up>

CTRL-W CTRL-K CTRL-W_CTRL-K CTRL-W_k
CTRL-W k Move cursor to Nth window above current one. Uses the cursor position to select between alternatives.

CTRL-W <Left> CTRL-W_<Left>

CTRL-W CTRL-H CTRL-W_CTRL-H

CTRL-W <BS> CTRL-W_<BS> CTRL-W_h
CTRL-W h Move cursor to Nth window left of current one. Uses the cursor position to select between alternatives.

CTRL-W <Right> CTRL-W_<Right>

CTRL-W CTRL-L CTRL-W_CTRL-L CTRL-W_l
CTRL-W l Move cursor to Nth window right of current one. Uses the cursor position to select between alternatives.

CTRL-W w CTRL-W_w CTRL-W_CTRL-W
CTRL-W CTRL-W Without count: move cursor to the focusable window below/right of the current one. If none, go to the top-left window. With count: go to Nth window (numbered top-left to bottom-right), skipping unfocusable windows. To obtain the window number see bufwinnr() and winnr(). When N is larger than the number of windows go to the last focusable window.

CTRL-W_W

CTRL-W W Without count: move cursor to the focusable window above/left of current one. If none, go to the bottom-right window. With count: go to Nth window, like CTRL-W w.

CTRL-W t CTRL-W_t CTRL-W_CTRL-T
CTRL-W CTRL-T Move cursor to top-left window.

CTRL-W b CTRL-W_b CTRL-W_CTRL-B
CTRL-W CTRL-B Move cursor to bottom-right window.

CTRL-W p CTRL-W_p CTRL-W_CTRL-P
CTRL-W CTRL-P Go to previous (last accessed) window.

CTRL-W_P E441
CTRL-W P Go to preview window. When there is no preview window this is an error.

If Visual mode is active and the new window is not for the same buffer, the Visual mode is ended. If the window is on the same buffer, the cursor position is set to keep the same Visual area selected.

:winc :wincmd
These commands can also be executed with ":wincmd":

:[count]winc[md] {arg}
:winc[md] [count] {arg}
  Like executing CTRL-W [count] {arg}. Example:

```
:wincmd j
```

  Moves to the window below the current one.
  This command is useful when a Normal mode cannot be used (for the CursorHold autocommand event). Or when a Normal mode command is inconvenient.
  The count can also be a window number. Example:

```
:exe nr .. "wincmd w"
```

  This goes to window "nr".

Note: All CTRL-W commands can also be executed with :wincmd, for those places where a Normal mode command can't be used or is inconvenient (e.g. in a browser-based terminal).

5. Moving windows around window-moving

CTRL-W r CTRL-W_r CTRL-W_CTRL-R E443
CTRL-W CTRL-R Rotate windows downwards/rightwards. The first window becomes the second one, the second one becomes the third one, etc. The last window becomes the first window. The cursor remains in the same window.
  This only works within the row or column of windows that the current window is in.

CTRL-W_R

CTRL-W R Rotate windows upwards/leftwards. The second window becomes the first one, the third one becomes the second one, etc. The first window becomes the last window. The cursor remains in the same window.
  This only works within the row or column of windows that the current window is in.

CTRL-W x CTRL-W_x CTRL-W_CTRL-X
CTRL-W CTRL-X Without count: Exchange current window with next one. If there is no next window, exchange with previous window.

With count: Exchange current window with Nth window (first
window is 1). The cursor is put in the other window.
When vertical and horizontal window splits are mixed, the
exchange is only done in the row or column of windows that the
current window is in.

The following commands can be used to change the window layout. For example,
when there are two vertically split windows, CTRL-W K will change that in
horizontally split windows. CTRL-W H does it the other way around.

CTRL-W_K

CTRL-W K Move the current window to be at the very top, using the full
width of the screen. This works like :topleft split, except
it is applied to the current window and no new window is
created.

CTRL-W_J

CTRL-W J Move the current window to be at the very bottom, using the
full width of the screen. This works like :botright split,
except it is applied to the current window and no new window
is created.

CTRL-W_H

CTRL-W H Move the current window to be at the far left, using the
full height of the screen. This works like
:vert topleft split, except it is applied to the current
window and no new window is created.

CTRL-W_L

CTRL-W L Move the current window to be at the far right, using the full
height of the screen. This works like :vert botright split,
except it is applied to the current window and no new window
is created.

CTRL-W_T

CTRL-W T Move the current window to a new tabpage. This fails if
there is only one window in the current tabpage.
This works like :tab split, except the previous window is
closed.
When a count is specified the new tabpage will be opened
before the tabpage with this index. Otherwise it comes after
the current tabpage.

6. Window resizing window-resize

CTRL-W_=

CTRL-W = Make all windows (almost) equally high and wide, but use
'winheight' and 'winwidth' for the current window. Windows
with 'winfixheight' set keep their height, and windows with
'winfixwidth' set keep their width.

To equalize only vertically (each window equally high) use:

```
:vertical wincmd =
```

To equalize only horizontally (each window equally wide) use:

```
:horizontal wincmd =
```

To equalize windows when Nvim itself is resized, see
VimResized.

:res[ize] -N :res :resize CTRL-W_-
CTRL-W - Decrease current window height by N (default 1).
If used after :vertical: decrease width by N.

:res[ize] +N CTRL-W_+

CTRL-W + Increase current window height by N (default 1).
If used after :vertical: increase width by N.

:res[ize] [N]
CTRL-W CTRL-_ CTRL-W_CTRL-_ CTRL-W__
CTRL-W _ Set current window height to N (default: highest possible).

:{winnr}res[ize] [+-]N
Like :resize above, but apply the size to window {winnr}
instead of the current window. See also nvim_win_resize().

z{nr}<CR> Set current window height to {nr}.

CTRL-W_<

CTRL-W < Decrease current window width by N (default 1).

CTRL-W_>

CTRL-W > Increase current window width by N (default 1).

:vert[ical] res[ize] [N] :vertical-resize CTRL-W_bar
CTRL-W | Set current window width to N (default: widest possible).

You can also resize a window by dragging a status line up or down with the mouse. Or by dragging a vertical separator line left or right. This only works if the version of Vim that is being used supports the mouse and the 'mouse' option has been set to enable it.

The option 'winheight' ('wh') is used to set the minimal window height of the current window. This option is used each time another window becomes the current window. If the option is '0', it is disabled. Set 'winheight' to a very large value, e.g., '9999', to make the current window always fill all available space. Set it to a reasonable value, e.g., '10', to make editing in the current window comfortable.

The equivalent 'winwidth' ('wiw') option is used to set the minimal width of the current window.

When the option 'equalalways' ('ea') is set, all the windows are automatically made the same size after splitting or closing a window. If you don't set this option, splitting a window will reduce the size of the current window and leave the other windows the same. When closing a window, the extra lines are given to the window above it.

The 'eadirection' option limits the direction in which the 'equalalways' option is applied. The default "both" resizes in both directions. When the value is "ver" only the heights of windows are equalized. Use this when you have manually resized a vertically split window and want to keep this width. Likewise, "hor" causes only the widths of windows to be equalized.

The option 'cmdheight' ('ch') is used to set the height of the command-line. If you are annoyed by the hit-enter prompt for long messages, set this option to 2 or 3.

If there is only one window, resizing that window will also change the command line height. If there are several windows, resizing the current window will also change the height of the window below it (and sometimes the window above it).

The minimal height and width of a window is set with 'winminheight' and 'winminwidth'. These are hard values, a window will never become smaller.

WinScrolled and WinResized autocommands

win-scrolled-resized

If you want to get notified of changes in window sizes, the WinResized autocommand event can be used.
If you want to get notified of text in windows scrolling vertically or horizontally, the WinScrolled autocommand event can be used. This will also trigger in window size changes.
Exception: the events will not be triggered when the text scrolls for 'incsearch'.

WinResized-event

The WinResized event is triggered after updating the display, several windows may have changed size then. A list of the IDs of windows that changed since last time is provided in the v:event.windows variable, for example:

```
        [1003, 1006]
```

WinScrolled-event

The WinScrolled event is triggered after WinResized, and also if a window was scrolled. That can be vertically (the text at the top of the window changed) or horizontally (when 'wrap' is off or when the first displayed part of the first line changes). Note that WinScrolled will trigger many more times than WinResized, it may slow down editing a bit.

The information provided by WinScrolled is a dictionary for each window that has changes, using the window ID as the key, and a total count of the changes with the key "all". Example value for v:event:

```
{
   all:  {width: 0, height:  2, leftcol: 0, skipcol: 0, topline: 1, topfill: 0},
   1003: {width: 0, height: -1, leftcol: 0, skipcol: 0, topline: 0, topfill: 0},
   1006: {width: 0, height:  1, leftcol: 0, skipcol: 0, topline: 1, topfill: 0},
}
```

Note that the "all" entry has the absolute values of the individual windows accumulated.

If you need more information about what changed, or you want to "debounce" the events (not handle every event to avoid doing too much work), you may want to use the winlayout() and getwininfo() functions.

WinScrolled and WinResized do not trigger when the first autocommand is added, only after the first scroll or resize. They may trigger when switching to another tabpage.

The commands executed are expected to not cause window size or scroll changes. If this happens anyway, the event will trigger again very soon. In other words: Just before triggering the event, the current sizes and scroll positions are stored and used to decide whether there was a change.

7. Argument and buffer list commands

buffer-list

args list	buffer list	meaning

```
1. :[N]argument [N]     11. :[N]buffer [N]      to arg/buf N
2. :[N]next [file ..]   12. :[N]bnext [N]       to Nth next arg/buf
3. :[N]Next [N] 13. :[N]bNext [N]       to Nth previous arg/buf
4. :[N]previous [N]     14. :[N]bprevious [N]   to Nth previous arg/buf
5. :rewind / :first     15. :brewind / :bfirst  to first arg/buf
6. :last                16. :blast              to last arg/buf
7. :all         17. :ball               edit all args/buffers
                        18. :unhide             edit all loaded buffers
                        19. :[N]bmod [N]        to Nth modified buf
```

split & args list	split & buffer list	meaning

```
21. :[N]sargument [N]   31. :[N]sbuffer [N]     split + to arg/buf N
22. :[N]snext [file ..] 32. :[N]sbnext [N]      split + to Nth next arg/buf
23. :[N]sNext [N]       33. :[N]sbNext [N]      split + to Nth previous arg/buf
24. :[N]sprevious [N]   34. :[N]sbprevious [N]  split + to Nth previous arg/buf
25. :srewind / :sfirst   35. :sbrewind / :sbfirst split + to first arg/buf
26. :slast               36. :sblast            split + to last arg/buf
27. :sall                37. :sball             edit all args/buffers
                         38. :sunhide           edit all loaded buffers
                         39. :[N]sbmod [N]      split + to Nth modified buf

40. :args               list of arguments
41. :buffers            list of buffers
```

The meaning of [N] depends on the command:
 [N] is the number of buffers to go forward/backward on 2/12/22/32,
     3/13/23/33, and 4/14/24/34
 [N] is an argument number, defaulting to current argument, for 1 and 21
 [N] is a buffer number, defaulting to current buffer, for 11 and 31
 [N] is a count for 19 and 39

Note: ":next" is an exception, because it must accept a list of file names
for compatibility with Vi.

The argument list and multiple windows

The current position in the argument list can be different for each window.
Remember that when doing ":e file", the position in the argument list stays
the same, but you are not editing the file at that position. To indicate
this, the file message (and the title, if you have one) shows
"(file (N) of M)", where "(N)" is the current position in the file list, and
"M" the number of files in the file list.

All the entries in the argument list are added to the buffer list. Thus, you
can also get to them with the buffer list commands, like ":bnext".

:[N]al[l][!] [N] :al :all :sal :sall
:[N]sal[l][!] [N]
Rearrange the screen to open one window for each argument.
All other windows are closed. When a count is given, this is
the maximum number of windows to open.
With the :tab modifier open a tabpage for each argument.
When there are more arguments than 'tabpagemax' further ones
become split windows in the last tabpage.
When the 'hidden' option is set, all buffers in closed windows
become hidden.
When 'hidden' is not set, and the 'autowrite' option is set,
modified buffers are written. Otherwise, windows that have
buffers that are modified are not removed, unless the [!] is
given, then they become hidden. But modified buffers are
never abandoned, so changes cannot get lost.
[N] is the maximum number of windows to open. 'winheight'
also limits the number of windows opened ('winwidth' if
:vertical was prepended).
Buf/Win Enter/Leave autocommands are not executed for the new
windows here, that's only done when they are really entered.
If autocommands change the window layout while this command is
busy an error will be given. E249

:[N]sa[rgument][!] [++opt] [+cmd] [N] :sa :sargument
Short for ":split | argument [N]": split window and go to Nth
argument. But when there is no such argument, the window is
not split. Also see ++opt and +cmd.

:[N]sn[ext][!] [++opt] [+cmd] [file ..] :sn :snext
Short for ":split | [N]next": split window and go to Nth next
argument. But when there is no next file, the window is not
split. Also see ++opt and +cmd.

:[N]spr[evious][!] [++opt] [+cmd] [N] :spr :sprevious
:[N]sN[ext][!] [++opt] [+cmd] [N] :sN :sNext
Short for ":split | [N]Next": split window and go to Nth
previous argument. But when there is no previous file, the
window is not split. Also see ++opt and +cmd.

:sre :srewind
:sre[wind][!] [++opt] [+cmd]
Short for ":split | rewind": split window and go to first argument. But when there is no argument list, the window is not split. Also see ++opt and +cmd.

:sfir :sfirst
:sfir[st] [++opt] [+cmd]
Same as ":srewind".

:sla :slast
:sla[st][!] [++opt] [+cmd]
Short for ":split | last": split window and go to last argument. But when there is no argument list, the window is not split. Also see ++opt and +cmd.

:dr :drop
:dr[op] [++opt] [+cmd] {file} ..
Edit the first {file} in a window.

- If the file is already open in a window change to that window.
- If the file is not open in a window edit the file in the current window. If the current buffer can't be abandoned, the window is split first.
- Windows that are not in the argument list or are not full width will be closed if possible.

The argument-list is set, like with the :next command.
The purpose of this command is that it can be used from a program that wants Vim to edit another file, e.g., a debugger.
When using the :tab modifier each argument is opened in a tabpage. The last window is used if it's empty.
Also see ++opt and +cmd.

8. Do a command in all buffers or windows list-repeat

:windo

:[range]windo {cmd} Execute {cmd} in each focusable window, or only for windows in a given [range] of window numbers. It works like doing this:

```
CTRL-W t
:{cmd}
CTRL-W w
:{cmd}
etc.
```

This only operates in the current tabpage.
When an error is detected on one window, further windows will not be visited.
The last window (or where an error occurred) becomes the current window.
{cmd} can contain '|' to concatenate several commands.
{cmd} must not open or close windows or reorder them.

Also see :tabdo, :argdo, :bufdo, :cdo, :ldo, :cfdo and :lfdo.

:bufdo

:[range]bufdo[!] {cmd} Execute {cmd} in each buffer in the buffer list or if [range] is given only for buffers for which their buffer number is in the [range]. It works like doing this:

```
:bfirst
:{cmd}
:bnext
:{cmd}
etc.
```

When the current file can't be abandoned and the [!] is not present, the command fails.
When an error is detected on one buffer, further buffers will not be visited.
Unlisted buffers are skipped.
The last buffer (or where an error occurred) becomes the current buffer.
{cmd} can contain '|' to concatenate several commands.
{cmd} must not delete buffers or add buffers to the buffer list.
Note: While this command is executing, the Syntax autocommand event is disabled by adding it to 'eventignore'. This considerably speeds up editing each buffer.

Also see :tabdo, :argdo, :windo, :cdo, :ldo,
:cfdo and :lfdo.

Examples:

```
:windo set nolist foldcolumn=0 | normal! zn
```

This resets the 'list' option and disables folding in all windows.

```
:bufdo set fileencoding= | update
```

This resets the 'fileencoding' in each buffer and writes it if this changed
the buffer. The result is that all buffers will use the 'encoding' encoding
(if conversion succeeds).

9. Tag or file name under the cursor

window-tag

:sta :stag

:sta[g][!] [tagname]
Does ":tag[!] [tagname]" and splits the window for the found
tag. Refer to 'switchbuf' to jump to a tag in a vertically
split window or a new tabpage. See also :tag.

CTRL-W] CTRL-W_] CTRL-W_CTRL-]
CTRL-W CTRL-] Split current window in two. Use identifier under cursor as a
tag and jump to it in the new upper window.
In Visual mode uses the Visually selected text as a tag.
Make new window N high. Refer to 'switchbuf' to jump to a tag
in a vertically split window or a new tabpage.

CTRL-W g]

CTRL-W g] Split current window in two. Use identifier under cursor as a
tag and perform ":tselect" on it in the new upper window.
In Visual mode uses the Visually selected text as a tag.
Make new window N high.

CTRL-W g CTRL-]

CTRL-W g CTRL-] Split current window in two. Use identifier under cursor as a
tag and perform ":tjump" on it in the new upper window.
In Visual mode uses the Visually selected text as a tag.
Make new window N high.

CTRL-W f CTRL-W_f CTRL-W_CTRL-F
CTRL-W CTRL-F Split current window in two. Edit file name under cursor.
Like ":split gf", but window isn't split if the file does not
exist.
Uses the 'path' variable as a list of directory names where to
look for the file. Also the path for current file is
used to search for the file name.
If the name is a hypertext link that looks like
"type://machine/path", only "/path" is used.
If a count is given, the count'th matching file is edited.

CTRL-W F CTRL-W_F

Split current window in two. Edit file name under cursor and
jump to the line number following the file name. See gF for
details on how the line number is obtained.

CTRL-W gf CTRL-W_gf

Open a new tabpage and edit the file name under the cursor.
Like "tab split" and "gf", but the new tabpage isn't created
if the file does not exist.

CTRL-W gF CTRL-W_gF

Open a new tabpage and edit the file name under the cursor
and jump to the line number following the file name. Like
"tab split" and "gF", but the new tabpage isn't created if
the file does not exist.

CTRL-W gt CTRL-W_gt

Go to next tabpage, same as gt.

CTRL-W gT CTRL-W_gT

Go to previous tabpage, same as gT.

Also see CTRL-W_CTRL-I: open window for an included file that includes
the keyword under the cursor.

10. The preview window

preview-window

The preview window is a special window to show (preview) another file. It is
normally a small window used to show an include file or definition of a
function.

There can be only one preview window (per tabpage). It is created with one
of the commands below. The 'previewheight' option can be set to specify the
height of the preview window when it's opened. The 'previewwindow' option is

set in the preview window to be able to recognize it. The 'winfixheight' option is set to have it keep the same height when opening/closing other windows.

preview-popup

Alternatively, a floating window can be used by setting the 'previewpopup' option. When set, it overrules the 'previewwindow' and 'previewheight' settings.

:pt :ptag

:pt[ag][!] [tagname]
Does ":tag[!] [tagname]" and shows the found tag in a "Preview" window without changing the current buffer or cursor position. If a "Preview" window already exists, it is re-used (like a help window is). If a new one is opened, 'previewheight' is used for the height of the window. See also :tag.
See below for an example. CursorHold-example
Small difference from :tag: When [tagname] is equal to the already displayed tag, the position in the matching tag list is not reset. This makes the CursorHold example work after a :ptnext.

CTRL-W z CTRL-W_z

CTRL-W CTRL-Z CTRL-W_CTRL-Z :pc :pclose

:pc[lose][!]
Close any "Preview" window currently open. When the 'hidden' option is set, or when the buffer was changed and the [!] is used, the buffer becomes hidden (unless there is another window editing it). The command fails if any "Preview" buffer cannot be closed. See also :close.

:pp :ppop

:[count]pp[op][!]
Does ":[count]pop[!]" in the preview window. See :pop and :ptag.

CTRL-W } CTRL-W_}

Use identifier under cursor as a tag and perform a :ptag on it. Make the new Preview window (if required) N high. If N is not given, 'previewheight' is used.

CTRL-W g } CTRL-W_g}

Use identifier under cursor as a tag and perform a :ptjump on it. Make the new Preview window (if required) N high. If N is not given, 'previewheight' is used.

:pb :pbuffer

:[N]pb[uffer][!] [+cmd] [N]
Edit buffer [N] from the buffer list in the preview window. If [N] is not given, the current buffer remains being edited. See :buffer-! for [!]. This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag. Also see +cmd.

:ped :pedit

:ped[it][!] [++opt] [+cmd] {file}
Edit {file} in the preview window. The preview window is opened like with :ptag. The current window and cursor position isn't changed. Useful example:

```
:pedit +/fputc /usr/include/stdio.h
```

Also see ++opt and +cmd.

:ps :psearch

:[range]ps[earch][!] [count] [/]pattern[/]
Works like :ijump but shows the found match in the preview window. The preview window is opened like with :ptag. The current window and cursor position isn't changed. Useful example:

```
:psearch popen
```

Like with the :ptag command, you can use this to automatically show information about the word under the cursor. This is less clever than using :ptag, but you don't need a tags file and it will also find matches in system include files. Example:

```
:au! CursorHold *.[ch] ++nested exe "silent! psearch " .. expand("<cword>")
```

Warning: This can be slow.

Example CursorHold-example

```
:au! CursorHold *.[ch] ++nested exe "silent! ptag " .. expand("<cword>")
```

This will cause a ":ptag" to be executed for the keyword under the cursor, when the cursor hasn't moved for the time set with 'updatetime'. "++nested" makes other autocommands be executed, so that syntax highlighting works in the

preview window. The "silent!" avoids an error message when the tag could not
be found. Also see CursorHold. To disable this again:

```
:au! CursorHold
```

A nice addition is to highlight the found tag, avoid the ":ptag" when there
is no word under the cursor, and a few other things:

```
:au! CursorHold *.[ch] ++nested call PreviewWord()
:func PreviewWord()
:  if &previewwindow                    " don't do this in the preview window
:    return
:  endif
:  let w = expand("<cword>")             " get the word under cursor
:  if w =~ '\a'                  " if the word contains a letter
:
:    " Delete any existing highlight before showing another tag
:    silent! wincmd P                    " jump to preview window
:    if &previewwindow           " if we really get there...
:      match none                        " delete existing highlight
:      wincmd p                  " back to old window
:    endif
:
:    " Try displaying a matching tag for the word under the cursor
:    try
:       exe "ptag " .. w
:    catch
:      return
:    endtry
:
:    silent! wincmd P                    " jump to preview window
:    if &previewwindow           " if we really get there...
:        if has("folding")
:          silent! .foldopen             " don't want a closed fold
:        endif
:        call search("$", "b")           " to end of previous line
:        let w = substitute(w, '\\', '\\\\', "")
:        call search('\<\V' .. w .. '\>')       " position cursor on match
:        " Add a match highlight to the word at this position
:      hi previewWord term=bold ctermbg=green guibg=green
:        exe 'match previewWord "\%' .. line(".") .. 'l\%' .. col(".") .. 'c\k*"'
:      wincmd p                  " back to old window
:    endif
:  endif
:endfun
```

11. Using hidden buffers

buffer-hidden

A hidden buffer is not displayed in a window, but is still loaded into memory.
This makes it possible to jump from file to file, without the need to read or
write the file every time you get another buffer in a window.

:buffer-!

If the option 'hidden' ('hid') is set, abandoned buffers are kept for all
commands that start editing another file: ":edit", ":next", ":tag", etc. The
commands that move through the buffer list sometimes make the current buffer
hidden although the 'hidden' option is not set. This happens when a buffer is
modified, but is forced (with '!') to be removed from a window, and
'autowrite' is off or the buffer can't be written.

You can make a hidden buffer not hidden by starting to edit it with any
command, or by deleting it with the ":bdelete" command.

The 'hidden' is global, it is used for all buffers. The 'bufhidden' option
can be used to make an exception for a specific buffer. It can take these
values:

<empty>	Use the value of 'hidden'.
hide	Hide this buffer, also when 'hidden' is not set.
unload	Don't hide but unload this buffer, also when 'hidden' is set.
delete	Delete the buffer.

hidden-quit

When you try to quit Vim while there is a hidden, modified buffer, you will
get an error message and Vim will make that buffer the current buffer. You
can then decide to write this buffer (":wq") or quit without writing (":q!").
Be careful: there may be more hidden, modified buffers!

A buffer can also be unlisted. This means it exists, but it is not in the
list of buffers. unlisted-buffer

:files[!] [flags] :files

:buffers[!] [flags] :buffers :ls
:ls[!] [flags]
Show all buffers. Example:

1 #h "/test/text" line 1

2u "asdf" line 0
3 %a + "version.c" line 1

When the [!] is included the list will show unlisted buffers
(the term "unlisted" is a bit confusing then...).

Each buffer has a unique number. That number will not change,
thus you can always go to a specific buffer with ":buffer N"
or "N CTRL-^", where N is the buffer number.

For the file name these special values are used:
"[Prompt]" prompt-buffer
"[Scratch]" 'buftype' is "nofile"
"[No Name]" no file name specified

Indicators (chars in the same column are mutually exclusive):
u unlisted-buffer (only displayed when [!] is used)
% buffer in the current window
alternate-file buffer for :e# and CTRL-^
a an active buffer: loaded and visible
h hidden-buffer: loaded, but not displayed in a window
\- 'nomodifiable' buffer
= readonly buffer
R terminal buffer with a Running job (open channel)
F terminal buffer with a Finished job (closed channel)
? terminal buffer without a job: :terminal NONE
\+ 'modified' buffer
x buffer with read errors

[flags] can be a combination of the following characters,
which restrict the buffers to be listed:
\+ modified buffers
\- 'nomodifiable' buffers
= readonly buffers
a active buffers
u unlisted buffers (overrides the "!")
h hidden buffers
x buffers with a read error
% current buffer
alternate buffer
R terminal buffers with a Running job
F terminal buffers with a Finished job
t show time last used and sort buffers
Combining flags means they are "and"ed together, e.g.:
h+ hidden buffers which are modified
a+ active buffers which are modified

When using :filter the pattern is matched against the
displayed buffer name, e.g.:

```
filter /\.vim/ ls
```

:bad :badd

:bad[d] [+lnum] {fname}
Add file name {fname} to the buffer list, without loading it,
if it wasn't listed yet. If the buffer was previously
deleted, not wiped, it will be made listed again.
If "lnum" is specified, the cursor will be positioned at that
line when the buffer is first entered. Note that other
commands after the + will be ignored.

:balt

:balt [+lnum] {fname}
Like :badd and also set the alternate file for the current
window to {fname}.

:[N]bd[elete][!] :bd :bdel :bdelete E516
:bd[elete][!] [N]
Unload buffer [N] (default: current buffer) and delete it from
the buffer list. If the buffer was changed, this fails,
unless [!] is specified, in which case changes are lost.
The file remains unaffected. Any windows for this buffer are
closed. If buffer [N] is the current buffer, another buffer
will be displayed instead. This is the most recent entry in
the jump list that points into a loaded buffer.

Actually, the buffer isn't completely deleted, it is removed
from the buffer list unlisted-buffer and option values,
variables and mappings/abbreviations for the buffer are
cleared. If [N] is the last listed buffer in a window (i.e.,
there is no other listed buffer to switch to), the buffer is
emptied instead of being unloaded. The window is not closed,
and the buffer may be reused as a new buffer buffer-reuse.
This ensures every window always has a valid buffer.

Examples:

```
:.,$-bdelete " delete buffers from the current one to
" last but one
:%bdelete " delete all buffers
```

:bd[elete][!] {bufname} E93 E94
Like ":bdelete[!] [N]", but buffer given by name, see {bufname}.

:bd[elete][!] N1 N2 ...
Do ":bdelete[!]" for buffer N1, N2, etc. The arguments can be buffer numbers or buffer names (but not buffer names that are a number). Insert a backslash before a space in a buffer name.

:N,Mbd[elete][!]
Do ":bdelete[!]" for all buffers in the range N to M inclusive.

:[N]bw[ipeout][!] :bw :bwipe :bwipeout E517
:bw[ipeout][!] {bufname}
:N,Mbw[ipeout][!]
:bw[ipeout][!] N1 N2 ...
Like :bdelete, but really delete the buffer. Everything related to the buffer is lost. All marks in this buffer become invalid, option settings are lost, the jumplist and tagstack data will be purged, etc. Don't use this unless you know what you are doing. Examples:

```
:.+,$bwipeout   " wipe out all buffers after the current
                " one
:%bwipeout          " wipe out all buffers
```

:[N]bun[load][!] :bun :bunload E515
:bun[load][!] [N]
Unload buffer [N] (default: current buffer). The memory allocated for this buffer will be freed. The buffer remains in the buffer list.
If the buffer was changed, this fails, unless when [!] is specified, in which case the changes are lost.
Any windows for this buffer are closed. If buffer [N] is the current buffer, another buffer will be displayed instead.
This is the most recent entry in the jump list that points into a loaded buffer.

:bun[load][!] {bufname}
Like ":bunload[!] [N]", but buffer given by name.
Also see {bufname}.

:N,Mbun[load][!]
Do ":bunload[!]" for all buffers in the range N to M inclusive.

:bun[load][!] N1 N2 ...
Do ":bunload[!]" for buffer N1, N2, etc. The arguments can be buffer numbers or buffer names (but not buffer names that are a number). Insert a backslash before a space in a buffer name.

:[N]b[uffer][!] [+cmd] [N] :b :bu :buf :buffer E86
Edit buffer [N] from the buffer list. If [N] is not given, the current buffer remains being edited. See :buffer-! for [!]. This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Also see +cmd.

:[N]b[uffer][!] [+cmd] {bufname} {bufname}

Edit buffer for {bufname} from the buffer list. A partial name also works, so long as it is unique in the list of buffers.
Note that a buffer whose name is a number cannot be referenced by that name; use the buffer number instead. Same is true if the buffer name starts with a +, it will be interpreted as the start of a +cmd.
Insert a backslash before a space in a buffer name.
See :buffer-! for [!].
This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Also see +cmd.

:[N]sb[uffer] [+cmd] [N] :sb :sbuffer
Split window and edit buffer [N] from the buffer list. If [N] is not given, the current buffer is edited. Respects the "useopen" setting of 'switchbuf' when splitting. This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Also see +cmd.

:[N]sb[uffer] [+cmd] {bufname}
Split window and edit buffer for {bufname} from the buffer list. This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Note: If what you want to do is split the buffer, make a copy under another name, you can do it this way:

```
:w foobar | sp #
```

Also see +cmd.

:[N]bn[ext][!] [+cmd] [N] :bn :bnext E87
Go to [N]th next buffer in buffer list. [N] defaults to one.
Wraps around the end of the buffer list.
See :buffer-! for [!].
Also see +cmd.
If you are in a help buffer, this takes you to the next help
buffer (if there is one). Similarly, if you are in a normal
(non-help) buffer, this takes you to the next normal buffer.
This is so that if you have invoked help, it doesn't get in
the way when you're browsing code/text buffers. The next
three commands also work like this.

]b

]b Mapped to :bnext. default-mappings

:sbn :sbnext
:[N]sbn[ext] [+cmd] [N]
Split window and go to [N]th next buffer in buffer list.
Wraps around the end of the buffer list. Uses 'switchbuf'
Also see +cmd.

:[N]bN[ext][!] [+cmd] [N] :bN :bNext :bp :bprevious E88

[b

[b Mapped to :bprevious. default-mappings

:[N]bp[revious][!] [+cmd] [N]
Go to [N]th previous buffer in buffer list. [N] defaults to
one. Wraps around the start of the buffer list.
See :buffer-! for [!] and 'switchbuf'.
Also see +cmd.

:[N]sbN[ext] [+cmd] [N] :sbN :sbNext :sbp :sbprevious
:[N]sbp[revious] [+cmd] [N]
Split window and go to [N]th previous buffer in buffer list.
Wraps around the start of the buffer list.
Uses 'switchbuf'.
Also see +cmd.

:br[ewind][!] [+cmd] :br :bre :brewind
Go to first buffer in buffer list. If the buffer list is
empty, go to the first unlisted buffer.
See :buffer-! for [!].

[B

[B Mapped to :brewind. default-mappings

:bf[irst] [+cmd] :bf :bfirst
Same as :brewind.
Also see +cmd.

:sbr[ewind] [+cmd] :sbr :sbrewind
Split window and go to first buffer in buffer list. If the
buffer list is empty, go to the first unlisted buffer.
Respects the 'switchbuf' option.
Also see +cmd.

:sbf[irst] [+cmd] :sbf :sbfirst
Same as ":sbrewind".

:bl[ast][!] [+cmd] :bl :blast
Go to last buffer in buffer list. If the buffer list is
empty, go to the last unlisted buffer.
See :buffer-! for [!].

]B

]B Mapped to :blast. default-mappings

:sbl[ast] [+cmd] :sbl :sblast
Split window and go to last buffer in buffer list. If the
buffer list is empty, go to the last unlisted buffer.
Respects 'switchbuf' option.

:[N]bm[odified][!] [+cmd] [N] :bm :bmodified E84
Go to [N]th next modified buffer. **Note:** this command also
finds unlisted buffers. If there is no modified buffer the
command fails.

:[N]sbm[odified] [+cmd] [N] :sbm :sbmodified
Split window and go to [N]th next modified buffer.
Respects 'switchbuf' option.
Note: this command also finds buffers not in the buffer list.

:[N]unh[ide] [N] :unh :unhide :sun :sunhide
:[N]sun[hide] [N]
Rearrange the screen to open one window for each loaded buffer
in the buffer list. When a count is given, this is the
maximum number of windows to open.

:[N]ba[ll] [N] :ba :ball :sba :sball
:[N]sba[ll] [N] Rearrange the screen to open one window for each buffer in
the buffer list. When a count is given, this is the maximum
number of windows to open. 'winheight' also limits the number
of windows opened ('winwidth' if :vertical was prepended).
Buf/Win Enter/Leave autocommands are not executed for the new
windows here, that's only done when they are really entered.

When the :tab modifier is used new windows are opened in a
new tab, up to 'tabpagemax'.

Note: All the commands above that start editing another buffer, keep the 'readonly' flag as it was. This differs from the ":edit" command, which sets the 'readonly' flag each time the file is read.

12. Special kinds of buffers special-buffers

Instead of containing the text of a file, buffers can also be used for other purposes. A few options can be set to change the behavior of a buffer:

'bufhidden'	what happens when the buffer is no longer displayed in a window.
'buftype'	what kind of a buffer this is
'swapfile'	whether the buffer will have a swap file
'buflisted'	buffer shows up in the buffer list

A few useful kinds of a buffer:

quickfix — Used to contain the error list or the location list. See :cwindow and :lwindow. This command sets the 'buftype' option to "quickfix". You are not supposed to change this! 'swapfile' is off.

help — Contains a help file. Will only be created with the :help command. The flag that indicates a help buffer is internal and can't be changed. The 'buflisted' option will be reset for a help buffer.

terminal — A terminal window buffer, see terminal. The contents cannot be read or changed until the job ends.

directory — Displays directory contents. Can be used by a file explorer plugin. The buffer is created with these settings:

```
:setlocal buftype=nowrite
:setlocal bufhidden=
:setlocal noswapfile
```

The buffer name is the name of the directory and is adjusted when using the :cd command.

scratch-buffer

scratch — Contains text that can be discarded at any time. It is kept when closing the window, it must be deleted explicitly. Settings:

```
:setlocal buftype=nofile
:setlocal bufhidden=hide
:setlocal noswapfile
```

The buffer name can be used to identify the buffer, if you give it a meaningful name.

unlisted-buffer

unlisted — The buffer is not in the buffer list. It is not used for normal editing, but to show a help file, remember a file name or marks. The ":bdelete" command will also set this option, thus it doesn't completely delete the buffer. Settings:

```
:setlocal nobuflisted
```

Builtin plugin: zip

Nvim opens a read-only listing when :edit is used with a zip archive. The listing is a dir buffer with 'filetype' set to "zip"; entries open as read-only zip://{archive}/{path} buffers. Requires the unzip executable.

Recognized extensions include zip, jar, apk, epub, Office and OpenDocument formats, whl, xpi, pkpass, and cbz. Remote archives are fetched by vim.net.

Reading an entry from an encrypted archive prompts for its password.

g:loaded_nvim_zip_plugin

To disable the built-in zip browser, set this before startup:

```
vim.g.loaded_nvim_zip_plugin = 1
```

MAPPINGS zip-mappings

The standard dir-buffer-mappings, plus:

- x extracts the entry under the cursor into the current directory, discarding its path inside the archive. It never overwrites an existing file.

At the archive root, - opens the containing filesystem directory.

LIMITATIONS zip-limitations

Archive entries cannot be updated. Remote archives are not refetched on reload, and there is no PowerShell fallback, no custom backend command, and no support for the legacy g:zip_* variables. Use old-zip when those features are required.

Only the original zip encryption is supported, not AES.

Legacy plugin: zip old-zip

The legacy Vimscript zip plugin browses, updates, and extracts archive entries. It is not loaded by default; use :packadd to activate it:

```
vim.cmd.packadd('old-zip')
```

This can be done at any time. Its manual is then available as :help pi_zip.txt.
